these, calcium arsenate appears to be the most practical from the standpoint of cost, availability, and plant injury.

In a separate laboratory experiment with three insecticides it was observed that paris green and copper cyanide were capable of causing considerable mortality purely by contact with the under surface of the body. Calcium arsenate was the least toxic of the three as a contact poison.

Field tests using calcium arsenate (3 to 5 lb. to 1,000 sq. ft.) gave satisfactory results.

**Insecticide tests for cotton aphid and boll weevil control during 1941.** I. J. BECNEI and E. H. FLOYD. (La. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 623-626).—Experiments conducted in two localities with calcium arsenate alone and with other materials to determine their effect upon the cotton aphid, the boll weevil, and upon the yield of seed cotton are reported, the results being analyzed statistically. The cotton aphid and boll weevil infestations were lowest on plats receiving calcium arsenate plus 1 percent nicotine, the average yield increase over the checks being 359 lb. of seed cotton per acre; with calcium arsenate plus 10 percent sulfur and 0.5 percent rotenone 168 lb.; with calcium arsenate plus 10 percent sulfur and 0.2 percent pyrethrins 258 lb., and with calcium arsenate alone 323 lb.

**Control of insects in fourteen thousand corn bins.** M. D. FARRAR and W. P. FLINT. (Ill. Nat. Hist. Survey, Ill. Expt. Sta., and U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 615-619).—Of 12 fumigating mixtures tested at several dosage levels to determine their respective toxicity to grain insects, those offering the most promise as highly toxic fumigants for shelled corn in steel bins are ethylene dichloride-carbon tetrachloride (3-1)-methyl bromide 10 percent, propylene dichloride-carbon tetrachloride (3-1)-methyl bromide 10 percent, and Ethide-carbon tetrachloride and chloropierin-carbon tetrachloride. Satisfactory if sufficient dosage is used are ethylene dichloride-carbon tetrachloride (3-1), carbon bisulfide, carbon tetrachloride-carbon bisulfide (4-1), and similar proprietary mixtures. Methyl bromide when used alone was not a satisfactory grain fumigant in steel bins.

**Stem galls of sugar-cane induced with insect extracts.** J. P. MARTIN, (Hawaii. Sugar Planters' Expt. Sta.). (*Science*, 96 (1942), No. 2480, p. 39).—Reference is made to the production in 1936 of stem galls of sugarcane, for the first time, by artificial inoculations of extracts of the green leafhopper *Draeculacephala mollipes*, and evidence is presented indicating that the stimulus to gall formation is chemical in nature. In studies in 1941 galls were produced with an extract prepared from adults of the corn leafhopper *Peregrinus maidis* and the pink sugarcane mealybug *Trionymus sacchari*. It was shown that stem galls developed when extracts prepared from the corn and green leafhoppers were sterilized at 15 lb. steam pressure for 20 min., thus indicating that the stimulus to gall formation is chemical rather than biological in nature.

**The use of frass in the identification of forest insect damage.** R. F. MORRIS (*Canad. Ent.*, 74 (1942), No. 9, pp. 164-167, fig. 1).—This contribution includes a frass key for the identification of certain spruce defoliators.

**Lice and some other external parasites of domestic animals and poultry in the Province of Quebec.** W. E. WHITEHEAD (*Macdonald Col., McGill Univ., Farm Bul.* 7 (1942), pp. 27, pls. 6, figs. 2).

**The nymphal development for the [American cock]roach (*Periplaneta americana* L.),** J. T. GRIFFITHS and O. E. TAUBER. (Iowa Expt. Sta.). (*Jour. N. Y. Ent. Soc.*, 50 (1942), No. 3, pp. 263-272, fig. 1).—At a temperature of 29° C. (84.2° F.) the female American cockroach generally required 11 and the male 12 instars before reaching maturity. More stadia are necessary for some indi-

viduals. It is suggested that this increase may be due to unfavorable environmental conditions or bodily injury. The males averaged 276 (range 198–346) and the females 251 days (range 171–360) to complete their development at 29°. Similarly, at room temperature the females became adults sooner than did the males. Under laboratory conditions and at room temperature a complete reproductive cycle ("egg to egg") may be passed in about 243 days, but normally it takes about 15 mo. The entire life span (egg to "natural" death) usually extends over a period of about 630 days, but may last for more than 1,200 days. The regeneration of certain parts, such as portions of lost appendages, is possible throughout nymphal development.

**The compound 4,6-dinitro-o-cresol as a cockroach poison, J. B. GAHAN.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 669–673).—In toxicity tests against the American cockroach 4,6-dinitro-o-cresol was found to be more toxic and to kill more rapidly than either sodium fluoride or pyrethrum within a 3-day period, being more effective at a 5-percent concentration than pyrethrum at 5 percent or sodium fluoride at 50 percent. Exposure to the air in a room for 7 days did not destroy the toxicity of a 10-percent dust. In tests designed to eliminate the possibility of ingestion the compound was highly effective as a contact insecticide. Of seven materials tested as diluents, talc and redwood bark flour were found to be the most effective.

**Tartar emetic for thrips control on greenhouse carnations, R. D. EICHMANN** (*Washington Sta. Bul.* 417 (1942), pp. 35, figs. 10).—The onion thrips and the gladiolus thrips injure carnations in Washington greenhouses by rupturing the petal surface and ingesting the pigmented plant juices and by so doing produce decolorized areas. Since thrips spend most of the time inside the flowers bait type sprays are superior to contact insecticides. From 1 to 1.5 lb. of tartar emetic plus 3 lb. of white sugar per 100 gal. of spray gave excellent results. The varieties less susceptible to evidence of thrips damage have proved valuable to carnation producers.

**Control of the tobacco thrips on shade-grown tobacco in Connecticut, A. W. MORRILL, JR.** (U. S. D. A. coop. Conn. [New Haven] Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 646–649, fig. 1).—The results of experiments conducted with shade-grown tobacco at Windsor, Conn., from 1936 to 1941, inclusive, for the control of the tobacco thrips are reported, the details for 1938–41 being given in table form.

**Control of plant bugs in citrus groves, J. R. WATSON.** (Fla. Expt. Sta.). (*Citrus Indus.*, 23 (1942), No. 11, pp. 4–5)

**A study of leafhopper feeding injury to food manufacture and water-vapor loss of grape leaves, H. W. BRODY, N. F. CHILDERS, and G. E. MARSHALL.** (Ohio State Univ. and Purdue Univ.). (*Amer. Fruit Grower*, 61 (1941), No. 8, pp. 6, 14, figs. 4).

**The place of concentrated sprays in the pea aphid control program, H. GLASGOW.** (N. Y. State Expt. Sta. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 649–653, figs. 3).—Report is made of work conducted during the past 5 yr. with a view to determining the practicability of using highly concentrated sprays for pea aphid control.

**The summer host of *Aphis fabae* Scop., M. G. JONES** (*Bul. Ent. Res.*, 33 (1942), No. 3, pp. 161–169).—Experiments have shown that when spring migrants of *A. fabae* from *Euonymus europaeus* and *Viburnum opulus* are given a choice of summer host plants enclosed by a muslin cage they col nize bean first and then sugar beet. Dock, poppy, and *Chenopodium* are colonized in no very definite order, but thistle is the last plant to be infested. Further infestation of surrounding plants takes place rapidly by means of apterae, which migrate actively

and colonize plants at random. The total number of aphids on the summer host plants is of the same order as the times of colonization. The effect of parasites and predators is proportional to the numbers present and to the size of the colony.

**Propagation of black scale on potato sprouts, S. E. FLANDERS.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 687-689, figs. 2).—An account of the use of green potato sprouts for the mass propagation of black scale, which use is now as well established as is the use of bleached sprouts for the production of mealybugs.

**Control of hemipterous cotton insects by the use of dusts, J. R. EYER and J. T. MEDLER.** (N. Mex. Expt. Sta. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 630-634, fig. 1).—Of the pentatomid and mirid plant bugs that injure cotton in the irrigated valleys of southern New Mexico, *Adelphocoris superbus* (Uhl.) and species of the genera *Lygus* and *Chlorochroa* are the most important. In a block experiment conducted at State College in 1941 a substantial increase in the yield of cotton was found to result from the use of dusts of paris green and sulfur and calcium arsenate and sulfur. These arsenical-sulfur combinations also produced relatively high mortalities in the case of three species, i. e., Say stinkbug, *L. hesperus*, and *A. superbus*, confined in large field cages.

**Cooperative distribution of organisms causing milky disease of Japanese beetle grubs, R. T. WHITE and S. R. DUTKY.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 679-682).—Report is made of the progress of colonization work conducted by the U. S. Department of Agriculture in cooperation with 11 States and the District of Columbia in the distribution of milky disease organisms with a view to accelerating their natural spread.

**Laboratory tests of organic fumigants for wireworms, R. S. LEHMAN.** (U. S. D. A. coop. Wash. and Idaho Expt. Stas.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 659-661).—In a series of experiments conducted for the purpose of determining the effectiveness of various liquid organic compounds, 114 in number, as fumigants against wireworms, particularly the Pacific coast wireworm and the sugar beet wireworm in the soil, the median lethal concentration of 57 was determined. In this series allyl isothiocyanate proved to be the most toxic compound tested. When it was used in air alone in earlier experiments by the author (*E. S. R.*, 70, p. 511) practically the same results were obtained. Of all the fumigants tested in these experiments 10 showed median lethal concentrations lower than carbon disulfide and 46 higher. "Of the 9 compounds that were more toxic than carbon disulfide in air alone, only 3 were more toxic in the soil, and the relative toxicity was much less. The soil evidently absorbs much of the fumigant, making it less available to the insect. It is also true, as other (unpublished) tests have shown, that in the field diffusion plays an important part. Thus chloropicrin, which is 14.3 times as toxic as carbon disulfide in soil in the laboratory, is only twice as toxic in the field. Allyl isothiocyanate, which is 29.3 times as toxic in the laboratory, has about the same toxicity as carbon disulfide in the field. The greater toxicity of carbon disulfide to wireworms in the field is probably due to its ability to diffuse and its small loss by absorption in the soil."

The relative toxicities of some of the compounds tested as compared with carbon disulfide, when used both in soil and in air alone, are presented in a table.

**Control of flea beetles on cigar-wrapper tobacco with cube dust in the Florida-Georgia area, F. S. CHAMBERLIN and A. H. MADDEN.** (U. S. D. A. coop. Fla. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 634-637).—Report is made of experiments conducted at Quincy, Fla., 1938-40, to determine the proper schedule and number of applications of a cube root and tobacco dust mixture containing 1 percent of rotenone for the control of the tobacco flea beetle on

cigar-wrapper tobacco. The results indicate that the most profitable schedule may be expected to vary from season to season. One application per week, with a total of 11 applications for the season, gave the most economical control under conditions of heavy infestation, while 1 application every 10 days, with a total of 3 applications per season, was sufficient with a very light infestation. The authors are led to conclude that 1 application per week from transplanting time until the crop approaches maturity will normally give adequate protection.

**Toxicity of acrylonitrile, chloroacetonitrile, ethylene dichloride, and other fumigants to the confused flour beetle,** H. H. RICHARDSON and A. H. CASANGES. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 664-668, figs. 2).—Laboratory tests of the toxicity of certain chemicals as fumigants against the confused flour beetle in 5-hr. exposures at 25° C. are reported. Small volumes of chemicals as volatile as carbon disulfide were conveniently measured by use of a small hypodermic syringe attached to a micropipette. Acrylonitrile and chloroacetonitrile were the most toxic chemicals and appear worth further study as fumigants. They were also very toxic to the bedbug. "Other chemicals tested are listed by groups approximately in the order of decreasing toxicity, as follows: (1) Methyl bromide, 1,1-dichloro-1-nitropropane, and 1,1-dichloro-1-nitroethane, (2) methyl allyl chloride, methyl allyl bromide, and ethylene oxide, (3) carbon disulfide, and (4) ethyl bromide. Ethylene dichloride was found to have a delayed killing action which increased mortality considerably over a period of about 20 days after fumigation. A noninflammable mixture with carbon tetrachloride (3:1 by volume) also showed a latent effect, but the carbon tetrachloride added little or nothing to toxicity. Judging only from the mortality produced after 20 days, ethylene dichloride is not far below methyl bromide in the toxicity scale. However, beetles fumigated with these low concentrations of ethylene dichloride may lay viable eggs before death, and the dosages must be increased to prevent egg laying."

**Three curculionid pests of the oiticica nut,** L. PYENSON (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 715-718, figs. 2).—Report is made of observations on three curculionid pests of the oiticica tree (*Licania rigida*), namely, *Conotrachelus licaniae* Marsh. and two undetermined or possibly new species of the genus in the river valleys of Brazil. It is pointed out that recently the nuts of this tree have become of commercial importance as a source of a fairly light colored oil which greatly resembles tung oil in odor and in many of its other physical and chemical properties.

**Life history, habits, and control of the beanstalk weevil *Sternechus paludatus* in the Estancia Valley, New Mexico,** J. G. SHAW and J. R. DOUGLASS (U. S. Dept. Agr., *Tech. Bul.* 816 (1942), pp. 36, figs. 19).—*S. paludatus* (Casey), a new pest of bean plants, is found in the foothills of the Manzano Mountains which border the Estancia Valley on the west. In the spring most of the weevils leave their natural host, New Mexican locust (*Robinia neomexicana*), to feed on young bean plants in nearby fields. Damage or destruction of both hosts occurs from oviposition scars, larvae feeding within the stems and leaf petioles, and external feeding on tender areas by the adult. Life history studies revealed that the weevil has only one generation, and only the overwintered females oviposit. Eggs are deposited from May through August. Young bean plants were used for developmental studies, and sections of stems containing eggs and subsequently larvae were held in test tubes for observation. Full-grown larvae enter the soil to pupate, and to observe subterranean development a special rack to hold soil was constructed. The ends and bottom, made of wood, supported parallel pieces of glass, and adjoining these plates cells were molded to accommodate each larva. The developmental period from egg to adult required from about 50 to

70 days, and the rate of development compared with the average mean temperature suggests a linear relationship. Adults hibernate successfully in litter in the ponderosa pine and nut pine forest zones. Temperature seems to be the sole factor in influencing emergence from hibernation. Activity begins at about 45° F. The only known insect enemies of this weevil affect the egg stage, namely, a thrips and nymphs of the insidious flower bug *Orius insidiosus* (Say). Best control with insecticides under laboratory conditions was obtained with barium fluosilicate and zinc arsenite, the former having an immediate effect and the latter a much more delayed one.

**Certain plume moths of economic importance in California**, W. H. LANGE, JR. (Univ. Calif.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 718-724, figs. 6).—Report is made of the study of five species of Pterophoridae of the genus *Platyptilia*, which cause damage of economic importance in California either to agriculturally grown plants or, in one case, to plants of importance as sources of nectar for honeybees, namely, *P. carduidactyla* (Riley), *P. antirrhina* Lange, *P. williamsii* Grinnell, *P. fuscicornis* Zeller, and certain races of *P. pica* Wlsm.

**A survey of biological destruction of cactus on Nebraska range land**, M. W. PEDERSEN. (Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 8, pp. 769-770).—A survey of the destruction of cacti (*Opuntia hemifusa* and *O. fragilis*) on the range in the hard lands and sand hills near Valentine, Nebr., by the caterpillar of a pyralid moth of the genus *Melitara*, thought to be *M. dentata*, is reported. The author's observations indicate that in the areas covered the spread of these cacti is being effectively controlled by this caterpillar. While the ecology of this insect has not been worked out for this area, observations indicate that its activity should be taken into consideration in range management of short-grass vegetation.

**Supplementary control measures for codling moth**, A. M. WOODSIDE (*Virginia Sta. Bul.* 342 (1942), pp. 19, figs. 6).—Increasing difficulty in the control of codling moth by sprays has stimulated demand for information on the effectiveness of packing shed and general orchard sanitation, scraping of the trees, treating cavities and decayed places, proper pruning practices, chemically treated bands, and bait traps. This publication notes that a tightly constructed packing shed traps many moths escaping from orchard crates and storage. Cocoons in boxes can be killed by submergence in boiling water for 1 min. Prop poles should be stacked outside the orchard. Thinning in heavily infested orchards kills many larvae if this fruit is destroyed properly. Hibernating worms may be killed by scraping off the rough bark and burning it during the winter. Experimental results show that proper banding will reduce infestation 35 to 50 percent. Reductions of about 50 percent in fruit infestation have been obtained where a bait trap was used in each tree in time to catch the earliest of the spring-brood flight.

[**Codling moth control**] (*Vermont Sta. Bul.* 495 (1942), pp. 30, 31, fig. 1).—The results of further studies on moth flight by M. B. Cummings and C. H. Blasberg (*E. S. R.*, 86, p. 358) are reported.

**A study of codling moth oviposition in a mixed pear orchard**, C. C. HATTINGH (*Jour. Ent. Soc. South. Africa*, 5 (1942), pp. 137-146).

**Biological control of the codling moth in South Africa**, R. I. NEL (*Jour. Ent. Soc. South. Africa*, 5 (1942), pp. 118-137).

**Methyl bromide fumigation to control oriental fruit moth on dormant nursery stock**, A. C. JOHNSON, E. M. LIVINGSTONE, and J. W. BULGER (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 674-677, figs. 2).—In the search for a quick and economical method for the treatment of nursery stock hosts of the oriental fruit moth tests were made of trichloroethylene, ethyl formate,

methyl bromide, a mixture of ethylene oxide and ethylene dichloride, and ethylene dichloride alone, and methyl bromide was selected as the most promising. All stages of the insect were tested, the eggs and larvae being the most resistant. Dosages of 1.5 lb. of methyl bromide per 1,000 cu. ft. for a period of 4 hr. at 60° F. or 1 lb. at 70° were found to be lethal to overwintering larvae (the stage occurring on dormant nursery stock) in atmospheric fumigations. Recommended dosages for commercial use were 3 lb. per 1,000 cu. ft. for 4 hr. at 60° or 2 lb. for 4 hr. at 70°.

**Investigations on the control of the European corn borer** (*Connecticut [New Haven] Sta. Bul. 462 (1942), pp. 549-591, figs. 16*).—This contribution is presented in two parts, as follows:

*I. Biological aspects*, R. L. Beard (pp. 551-566).—Research conducted in 1940 and 1941 indicated that during the egg-laying period of the European corn borer moth eggs are deposited on plants smaller than the midwhorl stage. When eggs are deposited on plants smaller than the late whorl stage few of the emerging larvae become established. Beyond this stage of plant growth a gradient of survival increasing in the older plant stages appears. Due to escape from oviposition and inability to support larvae, plants smaller than the late whorl stage at the time of moth flight are not likely to be severely infested. The principal primary infestation is in the tassel in plants larger than the midwhorl stage and smaller than the early silking stage. The tassel in plants larger than the early silking stage does not support larvae, and the borers which were resident there secondarily infest other parts of the plant. Stalks absorb the principal part of the secondary infestation. Developing ears are the preferred location in plants of the early silking stage or larger. The borer attack in the ears, therefore, is due more to a primary infestation than to the migrants from the previously infested tassel.

*II. Studies of insecticides*, N. Turner (pp. 567-591).—Continuing earlier work (B. S. R., 77, p. 665), no definite advantage was found, in tests covering the period 1936-41, for the addition of spreading agents to ground derris or cube root for corn borer sprays. Dusts containing 1 percent rotenone in pure ground derris root were not as effective for European corn borer control as dual-fixed nicotine containing 4 percent nicotine. Inert materials impregnated with extracts of pure ground derris or pyrethrum flowers were not significantly less effective than rotenone dust. At lower percentage nicotine, nicotine bentonite was more toxic than dual-fixed nicotine, but the reverse was true when the nicotine content was increased. With nicotine bentonite approximately 11 percent nicotine would be required to be as effective as 4 percent nicotine in dual-fixed nicotine. Dust applications with hand dusters were more effective than by means of a power duster. Modifications of the standard schedule of four treatments at 5-day intervals for control of the first generation were less effective than the standard. Data indicate that in the tests made, where treatment was confined to the hatching period, number of treatments was more important in general than any of the timing tried. For control of second generation larvae four treatments applied at 7-day intervals was almost as effective as five treatment at 5-day intervals.

**Factors determining the reduction in yield of field corn by the European corn borer**, L. H. PATCH, G. W. STILL, M. SCHLOSBERG, and G. T. BOTTGER.

(U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 10, pp. 473-482, fig. 1).—Field corn plots were infested by hand with egg masses of the European corn borer to obtain different levels of population of borers. The reduction of yield within cornfields was linear up to 22 borers per plant. Data from 18 plantings of the Clarage variety in various localities in northwestern Ohio from 1929

through 1933 showed that the rates of yield reduction were 2.68 and 4.86 percent per borer per plant when normal yields were 85 and 28 bu. per acre, respectively. Yield from plantings of hybrids was reduced 3.02 percent per borer per plant when the normal yield was 85 bu. and 3.93 percent at a yield level of 105 bu. During drought the damage per borer at a given yield level appears to be increased. Soil types or fertility levels appeared to have no direct effect on the rate of yield reduction per borer. For a 4-yr. period the average normal yield of 85 bu. per acre for corn planted on the average date of May 9 was reduced 2.85 percent per borer compared with 4.71 percent for the same hybrids giving about the same average yield but planted 23 days later. Plants of the later plantings although infested at the same time as early plantings were in a relatively early stage of development and were more severely damaged because of the longer period of borer feeding before the critical period of ear production and the consequent weaker condition of the plants and the larger average size of borers during the period of ear production. Attempts to find hybrids able to maintain their yields in the presence of a given level of borer population to a greater degree than would other hybrids of equal yielding ability were without much success.

**Development of synthetic food media for use in nutrition studies of the European corn borer, G. T. BOTTGER.** (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 10, pp. 493-500).—information from various nutritional studies on the European corn borer was used in conducting a series of tests for rearing larvae on a synthetic food medium. Twenty food mediums formulated to approximate the composition of green corn tissue were placed in rearing receptacles and infested with newly hatched larvae. As many as 36 percent of the larvae confined to synthetic food survived to maturity. In one trial 30 percent and in four others 20 percent or more of the larvae pupated. Casein appeared superior to zein as a source of protein, while a 2:1 ratio of glucose to sucrose appeared to satisfy the carbohydrate requirement of growing larvae. The tests indicated that vitamins A, B<sub>1</sub>, and E are of nutritional value to European corn borer larvae, particularly in the absence of a sufficiently high concentration of casein in the food medium.

**Development and use of sugarcane varieties resistant to the sugarcane borer, R. MATHES and J. W. INGRAM.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 638-642).—Work under way from 1936 to 1941, inclusive, on the resistance of common varieties of sugarcane to the sugarcane borer, the comparative susceptibility to sugarcane borer injury of several promising new varieties of sugarcane potentially suitable for release to growers, and new varieties resistant to the borer is considered, accompanied by tabulated data.

**Tomato fruitworm control, J. L. HOERNER.** (Colo. Expt. Sta.). (*Canning Age*, 23 (1942), No. 10, p. 533).

**Results attained in the biological control of *Diatraea saccharalis* (F.) in Florida, L. C. SCARAMUZZA and J. W. INGRAM.** (U. S. D. A. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 642-645).—The work of introduction and colonization of sugarcane borer parasites is reported upon.

**Catálogo sistematico y zoogeografico de los lepidopteros Mexicanos.—I, Papilionoidea. II, Hesperioidea. III, Sphingoidea y Saturnioidea** [Systematic and zoogeographic catalog of the Lepidoptera of Mexico, I-III], C. C. HOFFMAN (*An. Inst. Biol.* [Univ. Nac. Mex.], 11 (1940), No. 2, pp. 639-739, figs. 2; 12 (1941), No. 1, pp. 237-294; 13 (1942), No. 1, pp. 213-256).—The several parts of this catalog deal with the Papilionoidea, Hesperioidea, and Sphingoidea and Saturnioidea, respectively. An index to the genera and species accompanies each of the parts.

**Notes on mosquitoes in Nebraska (Diptera: Culicidae),** H. D. TATE and W. W. WIRTH. (Nehr. Expt. Sta.). (*Ent. News*, 53 (1942), No. 8, pp. 211-215).—A list is given of 19 species of mosquitoes collected in Nebraska, accompanied by localities in the State in which they have been collected.

**Simple tests for estimating the suitability of mineral oils as mosquito larvicides,** W. A. L. DAVID (*Bul. Ent. Res.*, 33 (1942), No. 3, pp. 195-203).

**Biology of the narcissus bulb fly in the Pacific Northwest,** C. F. DOUCETTE, R. LATTA, C. H. MARTIN, R. SCHOPP, and P. M. EIDE (*U. S. Dept. Agr., Tech. Bul.* 809 (1942), pp. 67, figs. 28).—The narcissus bulb fly is a major pest of narcissus in the Pacific Northwest. Eggs are deposited at the base of the foliage or in the soil nearby and hatch in from 10 to 12 days. Larvae enter the bulbs in late May and June and develop through three instars to mature size by late September or October and overwinter in the bulbs. These leave the bulbs in early spring and pupate close to the soil surface, and adults emerge in May and June. Development of some larvae is retarded so they pass the first winter as second or third instars, reach maturity the second summer, and pupate the next spring. Larvae cause damage usually by entering through the basal plate and burrowing upward into the scale region, eventually consuming a large part of the bulb. Average infestation of narcissus in the Pacific Northwest has ranged between 2.5 and 4.5 percent, and the value of infested bulbs is estimated at from \$80,000 to \$100,000 each year. Natural larval mortality in commercial stocks has averaged between 25 and 51 percent of the larvae successfully entering the bulbs. In the Pacific Northwest natural enemies have not become important.

**Toxicity of paradichlorobenzene to third-instar larvae of the housefly,** H. C. MANIS, A. L. DUGAS, and I. FOX. (Iowa State Col.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 662-664, fig. 1).—In tests of the toxicity of paradichlorobenzene to the third-instar larvae of the housefly it was found that concentrations above 249.4 mg. per 100 gm. of treated food are quite toxic to the larvae, and at a concentration of 1,234.6 mg. per 100 gm. of treated food 100-percent mortality was obtained. The median lethal concentration of paradichlorobenzene was found to be 430.5 mg. per 100 gm. of treated food. Concentrations corresponding to 497.5 and 1,234.6 mg. per 100 gm. of treated food resulted in 100-percent mortality in open and closed garbage pails when applied as a layer over the top of the food. The toxic action of paradichlorobenzene in these experiments is apparently due to its combined actions as a fumigant and a stomach poison.

**Waste celery as a breeding medium for the stablefly or "dog fly," with suggestions for control,** S. W. SIMMONS and W. E. DOVE. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 709-715, figs. 2).—It has been found that in Florida waste celery is an important breeding place for the stablefly, more commonly known in that State as the dog fly. "At Sanford, Belle Glade, Sarasota, Wiersdale, and Island Grove the present methods of disposing of about 180,000 to 270,000 cu. yd. of waste celery have resulted in severe localized outbreaks. The maximum density of dog fly breeding was calculated at 54,462 flies per cubic foot, and in selected places the housefly breeding was even more dense. Soon after exposure green strippings became infested, and in a little less than 18 days they produced adult dog flies. Where infested strippings were plowed under, third-stage larvae and pupae continued to produce flies. One cage containing 36 sq. ft. of plowed-under strippings produced a total of 11,653 dog flies in 5 days. For the treatment of infested litter some effective insecticides were found, but on account of the expense and time involved in treating the huge quantities it is suggested that the waste be crushed at the washing plants and

that the pulp be conveyed automatically through a vat of diluted creosote or gas condensate. It appears that the saving from treating the smaller quantity of waste would more than offset the cost of the crushing machinery and insecticide."

**The cabbage maggot in North Carolina**, B. B. FULTON (*North Carolina Sta. Bul.* 335 (1942), pp. 24, figs. 7).—The cabbage maggot, a pest in the mountains of North Carolina, has three generations each year, but only the first is destructive to cabbage. Winter is spent in puparia in the soil. Flies emerging gradually increase until the mountain laurel starts to bloom and then decrease rapidly. Three applications of mercury insecticides gave good control of maggots in seedbeds. Late planting reduces or eliminates the need for insecticidal protection, for example maggot injury is greatly reduced if plant bed seeding is delayed until flowering dogwood is in full bloom. Proper location of seedbeds, washing roots of plants before setting, and elimination of fall hosts such as cabbage stumps and turnips aid in the reduction of infestations. Radishes as a trap crop proved of little value. Cabbage flea beetle injury is sometimes severe in seedbeds and is confused with cabbage maggot injury.

**Plague flea, *Xenopsylla cheopis*, in Kansas**, A. W. GRUNDMANN, H. P. BOLES, and J. E. ACKERT. (Kans. Expt. Sta.). (*Kans. Acad. Sci. Trans.*, 44 (1941), pp. 238-240).—A more detailed account of the oriental rat flea than that noted (E. S. R., 85, p. 511).

**Pollen grains in nectar and honey**, F. E. TODD and G. H. VANSSELL. (U. S. D. A. coop. Univ. Calif.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 728-731).—The data presented in tables include the pollen grains in hand-collected nectar, the frequency distribution of the number of pollen grains in the honey stomach of bees 15 min. after feeding as compared with the number immediately after feeding, the number of pollen grains in three types of food before feeding and after storage by the bees, a comparison of pollen counts in nectars from nine plants when collected by hand and by the bees, and the pollen content of bee-collected nectars arranged in order of increasing number of grains.

**Damage to highways by the mound-building prairie ant**, R. F. FRITZ and W. A. VICKERS. (Kans. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 725-727, fig. 1).—An account of the mound-building prairie ant *Pogonomyrmex occidentalis* Cress., which is abundant throughout central and western Kansas, especially along roads and highways, where conditions are favorable to its existence. Every year these ants do considerable damage to highway shoulders and surfaces because of their custom of clearing the shoulders of soil-binding vegetation and of building nests beneath the road surface. Control of this ant can be accomplished by evaporating carbon disulfide under a galvanized tub inverted over the mound.

**Some preliminary observations on the effect of sweetened ant poisons on bees**, F. SHAW. (Mass. State Col.). (*Gleanings Bee Cult.*, 70 (1942), No. 9, pp. 538-539).

**On a new species of *Ephialtes* (Hym.: Ichneumonidae) parasitizing the codling moth**, J. F. PERKINS (*Bul. Ent. Res.*, 33 (1942), No. 3, pp. 171-174).—An ichneumonid parasite of the codling moth reared in the south of France is described as new under the name *E. cydiae*.

**Effect of dormant sprays on parasites of the San Jose and terrapin scales**, J. A. COX. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 698-701, fig. 1).—In the laboratory insecticides commonly used in dormant sprays for orchard pests were quite toxic to parasites of the San Jose and terrapin scales. The parasites reared from the San Jose scale were *Prospaltella perniciosus* Tower, *P. diaspidicola* Silv., *Phycus varicornis* How., *Marietta carnesi* How., *Anagrus epos* Gir., and *Aphytis mytilaspidis* Le Baron, and from the terrapin scale

*Coccophagus fuscipes* How., *C. lycimnia* Walk., *P. varicornis* How., *Chiloneurinus microphagus* Mayr; *Thysanus pulchra* Gir., *M. mexicana* How., *Tetrastichus belpyri* Ashm., *Aphycus stomachosus* Gir., *Aphycus* sp., and *Asteropaeus* sp. It is apparent from the information gained that the present spray practices have a tendency to reduce the parasites in sprayed orchards.

**Metaphycus helvolus**, an encyrtid parasite of the black scale, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 690-698, figs. 2).—Observations of *M. helvolus* (Comp.), an encyrtid parasite of lecanine scales introduced into California from Africa in 1937, are reported. The importance of this parasite in the control of the black scale in South Africa was obscured by the influence of the Argentine ant on the relative abundance of the parasites of this scale, but since the establishment of *M. helvolus* in California in 1937 it has become a dominant factor there in the reduction of the black scale over wide areas. Its effectiveness is, in part, an effect of the predatory habits of the female adult, its exceptionally long oviposition period, its short life cycle, and its solitary parasitization of the stages of the host having the longest period of exposure. *M. helvolus*, *Coccophagus trifasciatus* Comp., and *M. lounsburyi* (How.) are compared as to certain biological characteristics. Insecticides tend to decrease the effectiveness of *M. helvolus* directly by destroying the female adults at a time when there is a scarcity of hosts harboring the immature parasites, or indirectly by bringing about an even-hatch condition of the host generations so that there is a lack of food for the parasites.

**A note on technique for routine examinations of parasitic hymenopterous larvae**, G. C. ULYETT and J. S. v. D. MERWE (*Jour. Ent. Soc. South. Africa*, 5 (1942), pp. 147-151).

**The distribution of the European spruce sawfly *Diprion polytomum* (Htg.) in the Scandinavian and eastern Baltic countries**, W. F. SELLERS. (U. S. D. A.). (*Bul. Ent. Res.*, 33 (1942), No. 3, pp. 149-159, pl. 1, fig. 1).—A survey of the Scandinavian and eastern Baltic countries has shown the most favorable habitats of the spruce sawfly in Europe, as noted by Reeks and Balch et al. (*E. S. R.*, 86, p. 813) to be in one-generation areas under conditions which provided a maximum of sun heat, moisture, and shelter near to the upper limits of spruce growth. The least favorable habitats are the drier, less humid places, especially in the two-generation areas. Sawflies were found everywhere on spruce from the German-Danish border in Denmark and in southern Norway to the northernmost spruce forests of Sweden and from far above the Arctic Circle in Finland southward through the eastern Baltic countries of Estonia, Latvia, and Lithuania. The range of distribution covered in this survey was from approximately latitude 55° in Denmark and Lithuania to latitude 68°45' in Finland. This includes most of the Scandinavian Peninsula, Fennoscandia, and the eastern Baltic countries. Spruce comprised from 25 to 40 percent of the productive forest land of this large area.

**An analysis of the biological control of the European spruce sawfly in New Hampshire, with particular reference to predators**, J. G. CONKLIN (*Ohio State Univ., Abs. Doctoral Diss.*, No. 37 (1942), pp. 63-73).—The marked reduction in the sawfly population during the years of the investigation here reported could not be attributed to the activities of predators, it being caused chiefly by an unidentified disease that affected the larval stages.

**Diapause and egg intoxication in *Diprion polytomum* Hartig**, A. R. GOBELL (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 677-679).

**A new Olesicampe parasite of *Pikonema* sawflies (Hymenoptera: Ichneumonidae)**, G. S. WALLEY (*Canad. Ent.*, 74 (1942), No. 10, pp. 193-194).—An ichneumonid parasite reared from two sawflies of the genus *Pikonema* (*P.*

*alaskensis* (Rohw.) and *P. dimmockii* (Cress.) is described as new under the name *O. pikoncmac*.

The insect-food and hymenopterous parasites of the South African poisonous "button spider" *Latrodectus indistinctus* Camb., A. J. HESSE (*Jour. Ent. Soc. South. Africa*, 5 (1942), pp. 45-63, figs. 3).

**Influence of leaf age and feeding injury on the citrus red mite, C. F. HENDERSON and J. K. HOLLOWAY.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 5, pp. 683-686).—Leaf injury caused by the feeding of the citrus red mite, rendering the leaves unsuitable as food, is shown to be a factor capable of causing the rapid reduction in mite populations that often occur when climatic conditions are apparently favorable and natural enemies are extremely scarce. Two reactions of the mite to leaf injury have been observed, namely, a high reduction in egg production accompanied by a slight increase in mortality. This would indicate some form of nutritional influence which had a more pronounced effect on egg production than on mortality. This reduction in egg production associated with leaf injury was not due to any toxic condition transmissible from one portion of the leaf to another. The numbers of eggs produced on young and medium-age leaves were significantly greater than on old leaves. Feeding injury influenced egg production to a much greater extent on flush-growth leaves than on older leaves.

**The season's experiments with red mite control, C. R. CUTRIGHT.** (Ohio Expt. Sta.). (*Ohio State Hort. Soc. Proc.*, 75 (1942), pp. 32-44).—A late-spring dormant application of petroleum oil is recommended as a spray for red mite control, experiments having shown somewhat better results to be obtained when a 4 percent oil is used rather than a 3 percent oil. Application just before the leaves appear is more effective than when applied while the buds are dormant. If necessary to apply an emergency spray against the mites during the summer months use of a rotenone spray with summer oil or a good sticker is recommended. It is pointed out that ground derris root (5 percent rotenone) can be used at 2.5 lb. per 100 gal. plus 0.5 percent oil or a good sticker.

**Antricola new genus, Amblyomma gertschi new species, and notes on Ixodes spinipalpis (Acarina: Ixodoidea), R. A. COOLEY and G. M. KOHLIS** (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 46, pp. 1733-1736, pl. 1, fig. 1).

**Notes on the biology, toxicity, and breeding of Ixodes holocyclus (Neumann), D. T. OXER and C. L. RICARDO** (*Austral. Vet. Jour.*, 18 (1942), No. 5, pp. 194-199).—Observations of the toxicity of larvae of *I. holocyclus* as well as that of the nymphs are reported. Under laboratory conditions larvae were kept alive for 162 days and nymphs for 275 days. These periods are considered to be longer than any previously recorded for the viability of larvae and nymphs. Several dogs were actively immunized against the adult tick. A brief description is given of methods adopted for the rearing of ticks.

**The microbial flora of the Rocky Mountain wood tick Dermacentor andersoni Stiles, E. A. STEINHAUS** (*Jour. Bact.*, 44 (1942), No. 4, pp. 397-404).—A study of the internal microbial flora of 2,502 specimens of *D. andersoni*, obtained from various sources, yielded 77 strains of bacteria, 2 of yeasts, at least 1 rickettsia (that of Rocky Mountain spotted fever), 1 rickettsialike organism, and 1 strain of bacteriophage. No acidfast bacteria, molds, spirochaetes or motile protozoa were observed in any of the ticks examined. Each of the 77 strains of bacteria was studied in detail with respect to their cultural, morphologic, physiologic, and pathogenic characteristics. Of 2,018 unfed adult ticks, only 1.6 percent harbored bacteria, but of 486 recently fed ticks, bacteria were found in a minimum percentage of 9.1. One possible explanation of the greater number of bacteria in recently fed ticks is the experimental finding that feeding ticks can ingest bacteria from the surface of skin to which they are attached.

## ANIMAL PRODUCTION

The design of animal husbandry experiments, E. W. CRAMPTON (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 263-276).—Attention is called to the importance of design in setting up animal husbandry experiments to make it possible through variance analysis to get answers to more problems with fewer animals than would be necessary if single factor designs were set up. A multiple factor arrangement has the advantage of greater comprehensiveness. An example with six primary treatments on high and low protein rations with and without fish meal for winter and summer pigs of the two sexes, and with and without yeast and skim milk fed separately and combined, is presented. The maximum loss in precision from a single factor design was calculated at about 1 percent. Examples of uses of variance analysis for digestion, feeding, and other trials are presented. The number of independent variables which may be studied by this method is limited only by practical considerations of time and the facilities required for the calculations.

[Abstracts of papers on livestock production and feeding for the thirty-fifth annual meeting of the American Society of Animal Production] (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 345-346, 349-350, 351-352, 353-358, 358, 359-360).—The following papers were summarized:

Effect of Supplying Phosphorus to Cattle, Grazing a Phosphorus-Deficient Range, Upon Beef Production, by W. H. Black, N. R. Ellis, and J. M. Jones (p. 345) (U. S. D. A. and Tex. Expt. Sta.); Relationship of Milk Production of Milking Shorthorn Dams to the Carcass Quality of Their Steer Progeny, by A. C. Cook, W. H. Black, B. Knapp, Jr., and R. W. Phillips (p. 345), The Muscle-Bone Ratio as an Index of Merit in Beef and Dual-Purpose Cattle, by O. G. Hankins, B. Knapp, Jr., and R. W. Phillips (p. 351), Ear Measurements in Relation to Pelt Thickness and Fur Characters of Karakul Lambs, by J. I. Hardy and V. L. Simmons (p. 356), Fineness of Fiber in Eight Sampling Areas on Yearling Rambouillet Ewes, by E. M. Pohle and R. G. Schott (p. 356), Clean Wool Yield Variation Among Regions of Rambouillet Fleeces, by E. M. Pohle, H. W. Wolf, and C. E. Terrill (pp. 356-357), Estimation of Clean Fleece Weight From Unscoured Fleece Weight and Staple Length, by C. E. Terrill, E. M. Pohle, and L. O. Emik (p. 357), A Study of the Fiber Density of the Fleeces of Rambouillet Sheep, by H. W. Wolf, W. M. Dawson, and E. M. Pohle (pp. 357-358), The Value of Legume Hays in the Rations of Fall Farrowed Pigs, by N. R. Ellis, J. H. Zeller, and J. N. King (p. 358), and The Relation Between Growth Rates, Weights and Scores for Pigs at Market Maturity, by A. E. Molln (pp. 359-360) (all U. S. D. A.); The Laxative Nature of Soybean Oilmeal in Rations for Fattening Cattle, by I. F. Edwards, R. R. Snapp, and W. E. Carroll (pp. 345-346), Using Protein Supplements as a Partial Substitute for Corn in the Rations of Fattening Cattle, by F. C. Francis and W. E. Carroll (p. 346), and Distillers' By-Products in Swine Rations, by J. L. Kridler, B. W. Fairbanks, and W. E. Carroll (p. 359) (all Ill. Sta.); Comparison of Protein Supplements for Yearling Steers, by R. B. Hinman, F. B. Morrison, J. I. Miller, C. S. Hobbs, and J. J. Wanderstock (p. 346), and The Relative Efficiency for Ruminants of the Protein Furnished by Common Protein Supplements, by J. I. Miller and F. B. Morrison (p. 353) (both Cornell Univ.); The "Penny-A-Pig" Program, by E. F. Ferrin (pp. 349-350) (Minn. Sta.); Measuring Results in Extension Work, by E. T. Robbins (p. 350) (Univ. Ill.); Factors Effecting Farm Horse Power Efficiency, by R. S. Hudson and L. H. Blakeslee (p. 350) (Mich. Sta. Col.); The Relation of Ultra-Violet Light and Temperature During Aging on Quality of Beef, by M. E. Enslinger, J. Sotola, J. A. McIntosh, C. C. Prouty, and J. Roberts (p. 351), and Fiber Diameter Studies of Different Body Areas, by M. E. Enslinger (pp. 355-

356) (both Wash. State Col.); The Preparation of Muscular Tissues for Histological Study in Normal and Frozen Meat, by E. Johnson, F. N. Andrews, and C. L. Shrewsbury (pp. 351-352) (Purdue Univ.); The Effect of Fasting on the Yield and Carcass Grade of Spring Lambs, by C. M. Kincaid (p. 352) (Va. Sta.); The Effect of Diet on Brood Sow Performance, by O. B. Ross, P. H. Phillips, and G. Bohstedt (p. 353) (Univ. Wis.); The Experimental Design Necessary to Obtain Relative Net Energy Values From Group Feeding Experiments Has Proved to Have Several Advantages, by B. R. Taylor and W. L. Blizzard (pp. 353-354), and Some Factors Encountered in Evaluating Feeds For Fattening Lambs From Feeding Experiments, by H. M. Briggs (p. 355) (both Okla. Sta.); The Digestible Nutrients in Bluegrass Molasses, Alfalfa-Molasses and Corn Silages, by R. B. Hallmark and W. P. Garrigus (p. 354) (Univ. Ky.); Pasture Adjustments in the War, by R. H. Lush (pp. 354-355); Chemical Composition, Grazing Value, and Vegetative Changes of Herbage in a Typical Plains Pasture, by W. N. McMillen, Q. Williams, and W. Langham (p. 355); Vitamins Required by Growing Pigs, by V. F. McRoberts and A. G. Hogan (p. 359) (Univ. Mo.); and Studies in Feeding Soybeans to Pigs, by W. J. Peterson, E. H. Hostetler, and A. O. Shaw (p. 360) (N. C. Sta.).

[Investigations with livestock by the North Carolina Station] (*North Carolina Sta. Rpt. 1941*, pp. 51-53, 54-56, figs. 2).—Brief results are reported on forest grazing with beef cattle; cottonseed meal proving a profitable supplement to reeds for finishing yearling steers; cottonseed meal as a more profitable supplement than corn for wintering beef cattle; creep-feeding for beef calves; tankage, peanut meal, and fish meal as supplements to corn for fattening pigs; minerals with hogged down soybeans; native ewes of Hampshire breeding more profitable than western ewes of Rambouillet-Hampshire crossing for lamb production; and a mineral mixture to increase lamb production for Hampshire ewes.

**New developments in bovine and poultry nutrition.** R. M. BETHEKE. (Ohio Expt. Sta.). (*North Amer. Vet.*, 23 (1942), No. 9, pp. 580-583).—Developments in the nutrition of cattle and chicks are briefly reviewed.

**The fluorine problem in livestock feeding.** H. H. MITCHELL. [Ill. Expt. Sta.]. (*Natl. Res. Council, Reprint and Cir. Ser.*, No. 113 (1942), pp. [2]+10).—The Committee on Animal Nutrition of the National Research Council recommended that the permissible levels of fluorine in the total dry feed be considered tentatively as 0.003 percent for cattle, sheep, and swine, and 0.01 for chickens. In the total grain rations for cattle and sheep there were recommended 0.004 and 0.006 percent, respectively. The levels are based on the results of other investigators, of which an extensive bibliography is presented. These suggestions allow for a considerable margin to take account of individuality in reactions and length of time over which the fluorine is fed.

**Vitamins for livestock.** A. G. HOGAN (*Missouri Sta. Bul.* 453 (1942), pp. 23, figs. 6).—There are compiled the vitamin requirements of the various classes of livestock and poultry, including the various sources of vitamins A, D, thiamin, riboflavin, niacin, and choline in the several feeding stuffs, and the amounts of these feeding stuffs needed to supply vitamins for the several classes of animals.

**Length of feeding period and number of animals required to measure economy of gain in progeny tests of beef bulls.** B. KNAPP, JR., R. W. PHILLIPS, W. H. BLACK, and R. T. CLARK. (U. S. D. A. and Mont. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 285-292, figs. 2).—Data on the efficiency of gains of 62 individually fed steers sired by 3 purebred Hereford bulls from purebred and high grade Hereford cows showed that a feeding period of 168 days was sufficient to indicate differences between progeny groups provided the data were adjusted to differences in the initial weights. These findings were based on an

analysis by variance and covariance methods. The slope of the mean weight and efficiency analyzed by least squares showed that five to six 28-day periods were needed. Differences in initial weight of 100 lb. were responsible for affecting one market grade, and differences of 100 lb. in total gains caused two-thirds of a market grade change. The first 8 progeny of a bull were considered to indicate his ability to transmit efficiency of feed utilization, and little additional information was gained from records on further progeny.

**Non-randomness of variations in daily weights of cattle**, G. A. BAKER and H. R. GUILBERT. (Univ. Calif.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 293-299, fig. 1).—Daily weights in two periods of 33 and 32 days each, of seven heifers and one steer and fed on a ration of alfalfa hay, rolled barley, raisin pulp, and cottonseed meal, showed that when free access was allowed to feed and water there was a positive correlation between deviations in the daily weights and the environmental temperature, but when water was limited at night there was no correlation with variations and daily temperatures. The studies indicated that in feeding trials adequate adjustment periods are necessary, and that in experiments weighing of more rather than less animals at the same time of day increased the accuracy.

**Cattle for the Tropics**, A. O. RHOD (U. S. Dept. Agr., Off. Foreign Agr. Relat., *Agr. in Americas*, 2 (1942), No. 12, pp. 229-231, figs. 2).—A review of progress and expected development of cattle in the warmer climates for beef and milk production.

**The influence of feeding low-nitrogen rations on the reliability of biological values**, J. I. MILLER and F. B. MORRISON. ([N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 9, pp. 429-451, figs. 6).—Data were supplied in three nitrogen balance experiments with 14 wether lambs. Methods employed in previous investigations (E. S. R., 81, p. 92) were employed. There were used high- and low-nitrogen rations which included dried skim milk, linseed meal, soybean meal, corn gluten meal, alfalfa hay, and timothy hay. It was apparent that a preliminary period of 10-12 days was sufficient for lambs to reach a more or less stable level of urinary and fecal nitrogen excretion on a low-protein ration. The additions of about 10 percent protein to low-protein rations of about 2.75 percent increased palatability and resulted in less loss of body weight. When dried skim milk was fed with or without linseed meal, urinary nitrogen losses were greater than when fed with the basal ration alone. The nitrogen of the dried skim milk did not appear to be completely utilized at the low nitrogen levels, but the fecal nitrogen showed it to be completely digested and that it did not affect the metabolic nitrogen losses. For about 30 days following a low-nitrogen feeding period of 20 days, nitrogen was more efficiently utilized but the protein was less well digested. Biological values were generally higher after a low-nitrogen period than were obtained by the same lambs prior to the low-nitrogen period.

**The effect of adding large amounts of cottonseed meal to a lamb fattening ration**, H. M. BRIGGS and V. G. HELLER. (Okla. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 277-284).—Digestion trials with 16 wether lambs on rations similar to those employed (E. S. R., 87, p. 101) showed for rations with the higher content of cottonseed meal a greater protein digestion coefficient, 77.3 percent as an average for three periods, as contrasted with 73.7 percent for rations containing the smaller amounts of cottonseed meal. There was also a greater digestibility of the nitrogen-free extract and fiber with lower cottonseed meal rations. Positive balances of calcium, phosphorus, magnesium, and nitrogen were obtained with both types of rations, resulting in

phosphorus storage but a reduction in calcium storage. Nitrogen intake was above what might be considered optimum levels.

**Measures of growth rate for use in swine selection, R. E. COMSTOCK, L. M. WINTERS, P. S. JORDAN, and O. M. KISER.** (Minn. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 8, pp. 379-389, fig. 1).—The average weekly gain of 203 suckling pigs in connection with the Regional Swine Breeding Laboratory investigations was shown to fluctuate from a regular weekly increase during 8 weeks. It is assumed that the suckling pigs suffered from a nutritional limitation after 6 weeks, regardless of the theoretical increase in milk production after this time. These data and other literature indicate that weaning weight is but slightly dependent on the pigs' genotype. Supplemental feeding prior to weaning makes the weaning weight a better measure of hereditary ability to grow. Correlations of the weaning weight with the rate of gain from weaning to 200 lb. ( $y$ ) and the rate of gain from 50 to 200 lb. ( $y_1$ ) are discussed. The results indicate that  $y$  is biased in favor of heavy weaning pigs and  $y_1$  in favor of light weaners. By the use of intrasire regressions of offspring on dam the heritability of  $y$ ,  $y_1$ , weaning weight, and 180-day weight is estimated, and the postweaning growth rates were more heritable than the other two characters. It is tentatively concluded that  $y$  would be more useful in selection for growth rate than  $y_1$ , since the former favors heavy weaning weights. This is a desirable but not highly heritable character.

**Vitamin B<sub>6</sub> (pyridoxine) in the nutrition of the pig, E. H. HUGHES and R. L. SQUIBB.** (Univ. Calif.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 320-325, figs. 2).—Fits were produced in pigs when kept on floors free of molds and yeasts and supplied with diets deficient in vitamin B<sub>6</sub> as used by Chick et al. (E. S. R., 82, p. 663). When these pigs were given 5 mg. of synthetic pyridoxin per 100 lb. live weight they made normal gains and returned to normal blood hemoglobin and normal healthy condition. The requirement of young pigs for pyridoxin hydrochloride was thus estimated as between 0 and 5 mg. per 100 lb. live weight. The results were based on three experiments with 24 pigs about 30 lb. in weight, one half of which were on deficient diets and the other half served as controls. In two of the experiments deficient symptoms were not apparent because of contamination from molds and yeasts.

**Nutritional inadequacy of beet molasses rations for swine, R. A. RASMUSSEN, H. H. SMITH, R. W. PHILLIPS, and T. J. CUNHA** (*Utah Sta. Bul.* 302 (1942), pp. 22, figs. 6).—A more detailed report (E. S. R., 87, p. 259) is given of studies with 182 pigs in which as little as 15 percent of beet molasses resulted in a nutritional disease when fed to pigs under 100 lb. live weight. When as much as nearly 40 percent was fed to pigs weighing approximately 100 lb. or over the disease did not develop.

**Smoked meats.—I, Bacteriological, chemical, and physical measurements on smoked and unsmoked bacon, W. H. WHITE, N. E. GIBBONS, A. H. WOODCOCK, and W. H. COOK** (*Canad. Jour. Res.*, 20 (1942), No. 9, Sect. D, pp. 263-275, figs. 2).—Smoking Wiltshire bacon was found to improve the quality and color and reduce the number of surface bacteria developing in storage. The study was conducted with right and left bacon sides from seven hogs subjected to cures and pumping with 30, 25, and 20 percent brines with and without nitrate. Samples were smoked immediately after pickling and others were held 10 days before smoking to simulate transportation. All were stored at  $-9.4^{\circ}$  C. Chemical and bacteriological examinations of the pickles and the development of fat rancidity were reported with results analyzed by variance.

**Rations and methods of feeding Rhode Island Red pullets, D. C. KENNAED and V. D. CHAMBERLIN** (*Ohio Sta. Bimo. Bul.* 219 (1942), pp. 165-171).—The

protein, mineral, and vitamin requirements of hens were shown to vary with production and body needs, and therefore free choice feeding of whole grain and mash permitted layers to satisfy individual differences and requirements. In the studies there were 5 groups of 42 Rhode Island Red pullets fed 10 mo. on rations with whole corn and oats and 24 and 32 percent protein mash supplements, or 17 percent protein mash supplements with and without skim milk powder. Slightly the best egg production and the lowest mortality and feed costs were produced by the group receiving whole oats and a 17-percent protein mash without milk products. Some feather picking and cannibalism occurred in those receiving whole oats and corn.

**The protein value of Alaska pea meal for chickens, J. S. CARVER, B. B. BOHREN, and J. W. COOK.** (*Washington Sta. Bul.* 418 (1942), pp. 16).—It was found that Alaska pea meal could replace 40–50 percent of the herring fish meal in the protein concentrate of chick starters or laying mash containing 11 and 18 percent protein, respectively. The experiment with the chicks was based on gains of 10 lots of 25 chicks each fed in duplicate over a 2-week period following a 2-week depletion period (*E. S. R.*, 85, p. 384). In the study with laying birds there were five rations fed to 39 hens in duplicate over a 280-day period. As good results in egg production were obtained with pea meal as with 45.6 percent soybean meal and 54.4 percent fish meal protein. There were no significant differences in feed consumption, mortality, egg weight, or quality as a result of feeding pea meal and fish meal 30:70 to equal parts of the proteins.

**Feeding-cane molasses as a constituent of poultry rations.—II, Molasses for adult chickens, W. H. OTT, R. V. BOUCHER, and H. C. KNANDEL.** (*Pa. Expt. Sta.*). (*Poultry Sci.*, 21 (1942), No. 6, pp. 536–539).—Statistical analyses of the egg production, hatchability, and body weights of over 550 hens continued (*E. S. R.*, 87, p. 838) on rations containing 0, 2, 4, and 6 percent cane molasses from 24 to 72 weeks of age showed no significant differences in performance in the first or second generations. The relative cost of yellow corn and feeding-cane molasses seems to be the determining factor in the relative use of these feeds.

**Dietary factors affecting feather growth, H. L. FULLER and H. L. WILCKE.** (*Iowa Expt. Sta.*). (*Poultry Sci.*, 21 (1942), No. 6, pp. 540–547, figs. 5).—In an attempt to determine whether or not the effect of wheat bran and oat hulls in accelerating the rate of feather growth was simply the result of improved general growth, and to attempt to isolate a factor or factors responsible (*E. S. R.*, 84, p. 803), water-extracted and autoclaved wheat bran and oat hulls and the water extract were added to basal rations consisting mainly of oat groats for 38 lots of 16–20 New Hampshire or Barred Plymouth Rock chicks. The New Hampshires were fed to 6 weeks and the Barred Plymouth Rocks 8–10 weeks of age. The lots receiving untreated oat hulls or wheat bran were the fastest feathering groups, followed closely by those receiving heated oat hulls or water extract of oat hulls. The slowest feathering groups were those receiving oat groats, sawdust, and water-extracted oat hulls. The rapid feathering chicks were usually the heaviest in body weights. The analysis by variance showed heated and untreated oat hulls to give the most rapid feather growth of New Hampshires, while autoclaved oat hulls gave the best growth in body weight. Considerable plumage abnormalities occurred in birds receiving water extract of oat hulls and sawdust. The evidence indicated that separate factors were involved in normal feather structure and normal pigmentation in the Barred Plymouth Rock chick. Only the factor or factors necessary for normal pigmentation was destroyed by autoclaving. It was not removed from oat hulls by successive water extractions.

**The effect of the diet of the hen on the shank color of her day-old chicks, J. C. HAMMOND, D. MILLER, and D. WHITSON.** (*U. S. D. A.*). (*Poultry Sci.*,

21 (1942), No. 6, pp. 525-527).—The inclusion of 3 percent of fortified cod-liver oil in the diet of laying hens interfered with the transfer of the pigment from the diet, through the eggs, to the shanks of the chicks. The average shank score (E. S. R., 86, p. 230) was 0.63 as contrasted with 2 or over in chicks from eggs of hens on rations containing 14 percent crude soybean oil, alfalfa leaf meal, soybean meal, and peanut meal. In another experiment shank color score was also reduced by the inclusion of 0.25 percent and 0.5 percent flowers of sulfur. The experiments were conducted with lots containing 50 pullets each.

**Hatchability in relation to the fat content of the diet, B. W. HEYWANG.** (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 521-524).—In two experiments with 200 laying White Leghorn pullets, there were no significant differences in the hatchability of the eggs or the mortality of the chicks produced with diets containing less than 1 percent fat or when 2, 4, and 8 percent of ground rice in the basal ration was replaced by equivalent amounts of corn oil. Thus, no statistical significance could be attributed to differences in the fat content of the diets.

**Evidence of new growth factors for chicks, E. L. JOHNSON, C. W. CARRICK, R. E. ROBERTS, and S. M. HAUGE.** (Ind. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 566-570).—Evidence is presented to indicate that there is a factor or factors present in casein or liver meal, essential for growth of chicks, but distinct from vitamin A, thiamin, riboflavin, nicotinic acid, pantothenic acid, para-aminobenzoic acid, choline, and pyridoxin. This factor was soluble in ether and ethanol and was thermostable. The study was conducted in three experiments with 8 lots of about 20 ♂ and ♀ chicks each fed for 8 weeks with selection for reduced viability in the second and third experiments. These studies were conducted by the use of supplements of casein untreated and treated with ether and ethanol, liver meal, and the purified products. The results showed the best growth to occur to an average of 8 weeks of age in ♂s when liver meal was added to the ration.

**Cow manure as a source of certain vitamins for growing chickens, J. C. HAMMOND.** (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 554-559, fig. 1).—Additions of a carefully dried cow manure to a low grade diet improved the growth of chicks up to 6 weeks of age but had no influence on the growth of chicks fed a high grade diet. Cow manure contains a factor that stimulates comb growth in ♂s and ♀s. Similar benefits were produced by alcohol extracts but not by water extracts. The experiment was conducted with 24 lots of 25 chicks each. No undesirable odors or flavors were detected in the meat.

**Riboflavin in rations for poultry, B. W. FAIRBANKS and T. S. HAMILTON.** (Univ. Ill.). (*North Amer. Vet.*, 23 (1942), No. 9, pp. 575-578).—A review is given of riboflavin effects and the results of deficiencies in poultry. The riboflavin contents are given for several of the more common ingredients of the poultry ration, together with the amounts of each feed per 100 lb. of the ration required to furnish 25 percent of the riboflavin needed by growing chicks.

**The comparative vitamin D requirements of White Leghorn and cross-bred chicks, V. HELMAN and L. W. TIGHE** (*Poultry Sci.*, 21 (1942), No. 6, pp. 511-514, figs. 2).—In a comparison of the vitamin D requirements of growing White Leghorn chicks with more rapidly growing Barred Plymouth Rock ♂ × Rhode Island Red ♀ crossbreds, both types were found to require approximately 50 A. O. A. C. units of vitamin D per 100 gm. of the chick ration to 5 weeks of age. In the conduct of the study 240 chicks of each type were fed in duplicate lots, supplying 0, 10, 20, 30, 40, and 50 units of vitamin D per 100 gm. of the diet.

**Further data on the relation between shell strength, potential hatchability and chick viability in the fowl, S. S. MUNRO** (*Sci. Agr.*, 22 (1942), No.

11, pp. 698-704).—Differences in the specific gravity of eggs between flocks did not serve as reliable indices of hatchability, but within flocks the differences were generally related to the hatching power of the eggs. There was also a higher mortality of chicks from eggs with lower specific gravity than was found in the flock as a whole. This was a further study (E. S. R., 84, p. 515) carried out on over 15,000 eggs produced at eight farms, and showed the peculiarities of eggs from each farm and the possibilities of environmental effects.

**Acorns one cause of olive-colored yolks**, M. W. OLSEN. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 497-499).—Single-Comb White Leghorn hens confined to individual cages and fed rations containing 25-50 percent ground acorn meats, 25 percent ground acorn hulls, and 25 percent whole acorns from white oaks produced eggs with olive yolks after 4-5 days' feeding. Similar results were obtained on yolk color when whole acorns from black oaks were fed. Of 58 eggs with olive yolks 60 percent of the fertile eggs hatched, whereas 79 percent of fertile eggs with yellow yolks developed normally.

**Some studies of leg bone deformities in turkeys**, H. M. NIELSEN and D. E. MADSEN. (Utah Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 500-504, fig. 1).—In investigations with turkey poults low manganese rations did not cause perosis. These studies were conducted with 137 poults divided into lots of about 15 each, one half of which were started at 8 weeks of age and the other half at 14 weeks of age on rations of high calcium and phosphorus with low and normal manganese rations. Normal amounts of calcium and phosphorus were employed. The blood phosphatase analyzed by variance showed that a significant increase occurred with perosis. There were three cases of bone deformity among 17 birds on the standard ration with 6 percent bonemeal. These rations also contained 34.2 mg. manganese per kilogram. Up to 31 weeks of age increases were the least in the groups receiving bonemeal. Blood acid soluble phosphorus and inorganic phosphorus in the plasma were not significantly different in any of the lots.

**The effect of age and weight of turkey eggs on the length of the incubation period**, M. W. OLSEN. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 532-535, figs. 2).—Study of the incubation period of 3,376 turkey eggs at 99.5°-100° F. showed that there was a variation from 25¼ to 28 days. A maximum of 5 hr. of this variation was attributed to egg weight. The average initial egg weight classes of 70-80 gm. required for incubation 637.6 hr., 80-90 gm. 639.8, and 90-100 gm. 641.6 hr. The incubation period was not influenced by the length of the storage period of 1-16 days at 55° prior to the incubation period.

## DAIRY FARMING—DAIRYING

[Abstracts of papers on dairy cattle, production, and feeding for the thirty-fifth annual meeting of the American Society of Animal Production] (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 347-348, 348-349, 352-353).—Results of the following studies are presented: The Evaluation of Grass Silage as a Succulent Feed, by C. B. Bender (pp. 347-348), and Can One Predict the Average Fat Test for a Lactation Period on the Basis of an Incomplete Record? by R. P. Reece (p. 349) (both N. J. Expt. Stas.); The Replacement Value of Cottonseed Meal in a Good Dairy Ration, by A. H. Kuhlman and W. D. Gallup (p. 348) (Okla. A. and M. Col.); and A Method of Equalized Feeding for Use in Lactation Studies With Dairy Cows, by H. L. Lucas and L. A. Maynard (pp. 348-349), and A Study of the Effect of Dietary Fat and the Fat Soluble Vitamins Upon Milk and Fat Production, by J. K. Loosli and H. L. Lucas (pp. 352-353) (both Cornell Univ.).

**Material presented at the Dairy Technology Conference, 1942** (*Columbus: Ohio State Univ., 1942, pp. [1]+IV+78*).—Abstracts on the following subjects were presented: New Developments in Dairy Cattle Feeding, by C. F. Monroe (pp. 1-2), and The Place of Milk in the National Defense Program, by W. E. Krauss (pp. 3-4) (both Ohio Expt. Sta.); Short-Time High-Temperature Pasteurization, by P. C. Stoltz (pp. 5-9); Relation of Thermophilic Bacteria to Pasteurization, by F. W. Fabian (pp. 10-11) (Mich. State Col.); The Applications of the Newer Phosphates in Dairy Operations, by C. T. Roland (pp. 12-15); The Wetting Agents—Their Properties and Applications, by F. M. Scales and M. Kemp (pp. 16-19); Homogenization, by A. W. Farrall (pp. 20-24); A Neglected Phase of Frozen Desserts Sanitation, by F. W. Fabian (pp. 25-26) (Mich. State Col.); The Butter Industry of Tomorrow, by N. R. Baker (pp. 27-30); New Frontiers in Dairy Sanitation, by M. E. Parker (pp. 31-34); Effective Can Washing, by V. Schwarzkopf (pp. 35-36); The Path to Quality, by M. E. Parker (p. 37); Milk Control Laws From the Public Health Standpoint, by M. J. Dotter (pp. 38-41); A Summary of State-Wide Dairy Products Scoring for 1941, by T. V. Armstrong (pp. 42-46) (Ohio State Univ.); Organizing the Work of the Fieldman, From the Viewpoint of Quality Improvement, by E. H. Parfitt (pp. 47-48); Chocolate Milk in the Dairy Industry, by R. A. Larson (pp. 49-50); Methods of Platform Inspection, by J. T. Smith (pp. 51-55); The Relationship of Nutrition to Animal Disease, by T. S. Sutton (pp. 56-58), and Sweetening Agents for Use in Ice Cream, by J. H. Erb (pp. 59-63) (all Ohio State Univ.); The Manufacture, Curing, and Merchandising of American Cheddar Cheese in Valve-Vented Cans, by H. L. Wilson (p. 64) (U. S. D. A.); and Recent Research on Shrinkage in Ice Cream, by J. H. Erb (pp. 65-67), Factors Affecting the Mold Mycelia Count of Butter, by W. L. Slatter (pp. 68-70), Vocational Agriculture and the Fieldman, by J. B. Clinch (pp. 71-73), Diabetic Ice Cream, by H. G. Nelson (pp. 74-76); and The Resazurin Test, by I. H. Burgwald (pp. 77-78) (all Ohio State Univ.).

[Experiments in producing and feeding of dairy cattle] (*North Carolina Sta. Rpt. 1941, pp. 53-54, fig. 1*).—Results are briefly reported on investigations of mastitis as the more important dairymen's problem; small grain-legume silage mixture as a satisfactory silage for yields; and limestone and phosphate for increasing vitamin A content of pastures.

[Investigations with dairy products and dairy cattle by the Vermont Station] (*Vermont Sta. Bul. 495 (1942), pp. 21-22, 23-24*).—Results by H. B. Ellenberger are briefly presented on the efficiency of fat removal by milk and dairy plants; variations in the calcium and phosphorus contents of milk samples with season of production and stage of lactation; relation of vitamin consumption and hay quality to total digestible nutrients required and growth of heifers and their calves; and role of frequency in use of sire, sperm motility, pH of vaginal fluid, sodium bicarbonate douche, and exercise of bull in artificial insemination of dairy cattle.

**Age and weight changes in reaction-time of dairy cattle**, E. B. BROADY. (Univ. Mo.). (*Growth, 6 (1942), No. 2, pp. 179-184, figs. 5*).—The reaction time of dairy cattle to an electric shock showed that the youngest and smallest animals reacted fastest. Differences in the reaction of the rat are assumed due to position and morphology (E. S. R., 85, p. 38). An apparatus for measuring reaction rates in large animals is described.

**The digestibility and utilization by dairy cows of nutrients from fertilized and unfertilized bluegrass pasture**, J. F. EHEART and A. D. PRATT (*Virginia Sta. Tech. Bul. 81 (1942), pp. 28, fig. 1*).—For practical purposes, herbage from unfertilized bluegrass pasture was found to meet the needs for milk production provided enough herbage was available to produce the energy

required to gather the herbage from the poor sod. However, the increased yield from fertilization justified such a practice. In connection with the study there were conducted in 1940 and 1941 a total of 14 digestion and balance trials of 5 days each with dairy cows producing an average of over 12,000 gm. of 4 percent milk per day. Analyses are reported of the nitrogen, carbohydrates, fats, and minerals consumed and found in the feces of the cows eating the fertilized and the unfertilized pasture grasses.

**Wintering rations for cattle**, R. R. THALMAN (*Nebraska Sta. Bul.* 343 [1942], pp. 44).—In several experiments with calves and heifers, comparisons were made of the feeding values of shelled corn, corn silage, and corn fodder in comparison with sorgo silage and whole and chopped sorgo fodder, alfalfa hay, cottonseed cake, tankage, soybean cubes, and limestone with cottonseed cake and molasses. Feeding these roughages with alfalfa hay or a little protein concentrate proved an economical method of utilizing and marketing the roughages. Slightly more gain was produced by an acre of corn silage than by an acre of fodder. Sorgo silage also proved more satisfactory than sorgo fodder. Corn silage and corn fodder were slightly superior to the sorgo products. Weedy silages had a diuretic effect. Limestone increased the average daily gains from corn silage and cottonseed cake, or sorgo silage and cottonseed cake. Older steers gained more rapidly than steer calves. Heifers made approximately the same gains during wintering as steers, but they were too fat for feeders and too thin for killing. Increased gains were produced with limited quantities of molasses.

**Wartime rations for young calves**, D. ESPE and C. Y. CANNON. [Iowa Expt. Sta.]. (*Holstein-Friesian World*, 39 (1942), No. 22, pp. 11, 61, figs. 2).—Holstein-Friesian calves from 3 to 9 weeks of age on reduced amounts of milk products fed a gruel of oatmeal and linseed meal made gains of 1 lb. per head per day. The low fiber in the oatmeal seemed to avoid scouring. Alfalfa hay was successfully fed to older calves with corn, oats, bran, and a protein concentrate, such as soybean meal.

**The effect of number of daily milkings upon persistency of milk production**, I. LUDWIN (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 300-308, fig. 1).—Persistency was increased by more frequent milking if a proportional measure of persistency was used, but when measured by actual rate of decline it was not affected by frequency of milking. A straight line relationship showed the decline in milk yield from the third to the ninth month. The study was made by comparison of persistency of 728 lactations of 364 cows, which were made at different frequencies of milking of 2, 3, or 4 times per day for entire lactations. Pairings were made from A. R. S. O. Holstein-Friesian records so that age, individuality, and herd environment were balanced and the same individual milked at different rates in 2 successive lactations, but with the order of frequency of milking reversed in the 2 cows of a pair in successive years.

**Improved milk goats: A guide for breeders, dairymen, and exhibitors**, W. L. TEWALT (*New York: Orange Judd Pub. Co.*, 1942, pp. 145, figs. 34).—This book gives descriptions and illustrations of the breeds of milk goats, with general directions for goat care and management.

**Ripening cheese in cans**, A. C. DAHLBERG and J. C. MARQUARDT (*New York State Sta. Tech. Bul.* 265 (1942), pp. 17).—Cheddar cheese from raw and pasteurized milk was packed in vented cans and under vacuum with ripening at 40°, 50°, and 60° F. Cheese ripened at 60° developed a good flavor in 2 mo., but colder temperatures interfered with flavor development and a longer time was required without developing full flavor. A good cheese flavor was produced in cheese packed under 7 and 22 in. of vacuum. There was a slight tallowiness at the surface when packed in vented cans under atmospheric conditions. When

less than 7 in. vacuum pressure was developed in the cans cheese from poor quality milk produced gas pressure in the cans, but cheese from the poorer quality milk could be stored and ripened for 2 mo. at 60° with 22 in. vacuum. The addition of 1 gm. of magnesium or calcium hydroxide per 12 oz. of cheese absorbed the gas, which was largely CO<sub>2</sub>. A satisfactory vacuum was maintained in raw milk cheese for 4 mo. by the use of magnesium hydroxide and in pasteurized milk cheese for 8 mo. at 50°. Cheddar cheese was well ripened in vacuum packs and in the presence of hydroxide without developing gas pressure. Limburger, Brie, Tilsiter, and Camembert were best canned under vacuum.

**Growth and enzyme activity of *Penicillium roqueforti*, R. THIRODEAU and H. MACY (Minnesota Sta. Tech. Bul. 152 (1942), pp. 56, figs. 10).**—A study was made of the physical and chemical properties of the mycelium of *P. roqueforti* cultures from four sources and cheese produced after additions of mycelium to the cheese curd. It was concluded that additions of the enzymes of *P. roqueforti* as 6 gm. of mycelium per 5 lb. of blue cheese at the time of hooping produced cheeses of fine quality. Such cheese was ready for the trade in about 5 mo. as compared with 10 mo. for the normal product. Growth of *P. roqueforti* was poor on Czapek medium, and no pellicles were formed. Ranges of pH 4 to 7.5 in the media had no influence on the growth of four strains. As a source of carbon, sucrose seemed as satisfactory as glucose, lactose, and tributyrin and more satisfactory than ethyl acetate. The source of nitrogen had a marked influence on growth. The highest yields of mycelium were obtained when ammonium sulfate was the source of nitrogen. Organic sources were generally favorable for growth, although the pellicle was weak. Growth was stimulated to different degrees by solid materials in the media, such as cork, paraffin, and glass. With 0.1 percent agar in the media which decreased the oxidation potential below 400 mv., growth was favored. The requirement for abundant growth and the formation of a thick resistant felt were best met by the standard medium of sucrose 30 gm., sodium nitrate 1.75, dipotassium phosphate 1, magnesium sulfate 0.4, potassium chloride 0.5, ferrous sulfate 0.01, and agar 1 gm. in 1 l. of solution consisting of 950 cc. of water and 50 cc. of skim milk. In studies of the proteolysis of *P. roqueforti* it was found that only one protease of the trypsin type was produced over a wide pH range as ascertained by formol titration. The optimum activity of the enzyme on a 1-percent casein substrate was obtained between pH 5.8 and 6.3. For proteolysis studies a digestion period less than 20 hr. was recommended. With 3 percent of butter-oil or cottonseed-oil emulsions in an acetate buffer, optimum activity of lipase was obtained between pH 5.3 and 7.5. Sugar retarded but agar and organic nitrogen increased the production of both protease and lipase. Enzymatic activity varied from strain to strain, but protease activity was not retarded by sodium chloride concentrations up to 4 percent, and for lipase 6 percent of sodium chloride. The enzymes of *P. roqueforti* seemed to be tenaciously adsorbed by the cells, and release was beginning only after 30 days when disintegration had started. The nature of the enzymes produced was not clear. They were difficult to liberate and isolate from the mycelium. The protease of *P. roqueforti* was precipitated when the aqueous solution was half saturated with ammonium sulfate.

**Using fruit purées to get new flavors in ribbon ice cream, D. K. TRESSLER. (N. Y. State Expt. Sta.). (Food Indus., 14 (1942), No. 9, pp. 49-51, 99, fig. 1).**—Recipes are given for the preparation of various pectinized fruit juices which have been successfully employed in experimental batches of ice cream.

## VETERINARY MEDICINE

**Animal sanitation and disease control**, R. R. DYKSTRA (*Danville, Ill.: Interstail.* [1942], pp. 558, figs. 91; rev. in *Jour. Amer. Vet. Med. Assoc.*, 101 (1942), No. 786, pp. 213-214).—The subject is treated in the several parts (51 chapters) of this work as follows: Some animal health factors (pp. 23-114), some animal disease factors (pp. 115-152), some methods of disease control (pp. 153-171), infections and their handling (pp. 172-216), external and internal parasites and their control (pp. 217-240), noninfectious, sporadic ailments (pp. 241-344), infectious and communicable ailments (pp. 345-415), some infectious and communicable ailments of barnyard fowl (pp. 416-443), parasites and disease (pp. 444-487), miscellaneous information (pp. 488-537), and livestock sanitary bureaus, boards, and commissions, and the veterinarian (pp. 538-546).

**Textbook of clinical parasitology, including laboratory identification and technic**, D. L. BELDING (*New York and London: D. Appleton-Century Co.*, [1942], pp. XXI+888, figs. 279).—Section 1 of this work is devoted to general parasitology (pp. 1-70), section 2 to the protozoa (pp. 71-222), section 3 the Nematelminthes or roundworms (pp. 223-386), section 4 the Cestoidea or tapeworms (pp. 387-454), section 5 the Trematoda or flukes (pp. 455-588), section 6 Arthropoda (pp. 589-768), and section 7 to technical methods for the diagnosis and treatment of parasitic infections (pp. 769-843). A bibliography is included (pp. 845-846).

**Blood: A review of the recent literature**, F. H. BETHELL, C. C. STURGIS, R. A. HERTIG, and O. T. MALLERY (*Arch. Int. Med.*, 69 (1942), Nos. 5, pp. 856-926; 6, pp. 1051-1126).—Presented with a list of 608 references to the literature reviewed.

**Blood grouping technic: A manual for clinicians, serologists, anthropologists, and students of legal and military medicine**, F. SCHIFF and W. C. BOYD (*New York: Interscience Pubs., Inc.*, 1942, pp. XIV+248, [pl. 1], figs. 45).—Following a foreword by K. Landsteiner and a preface by the junior author, who, following the death of the senior author, completed the work, (1) theoretical foundations (pp. 1-16), (2) general technic of blood group investigation (pp. 17-84), and (3) specific applications of blood grouping techniques (pp. 85-241), including directions for carrying out blood-grouping tests in selecting donors for transfusions, in connection with cases of disputed parentage, and other forensic applications and in anthropological studies, are presented. Eight sectional bibliographies are included.

**Spontaneous and experimental leukaemia in animals**, J. ENGELBRETH-HOLM (*Edinburgh: Oliver & Boyd*, 1942, pp. XXIII+245, figs. 44; rev. in *Science*, 96 (1942), No. 2484, pp. 136-138).—The five parts of this work deal with leukemia in birds and mammals, respectively, as follows: (1) Spontaneous leukemia in animals, (2) transmission experiments, (3) the role of heredity in animal leukemia, (4) attempts to produce leukemia experimentally, and (5) nature of the animal leukemias. A 25-page list of references to the literature is appended. The review is by J. Furth.

[**Contributions on livestock diseases**] (*Assoc. South. Agr. Workers Proc.*, 43 (1942), pp. 90, 109-111).—Contributions on livestock diseases and parasites presented at the annual convention of the Association of Southern Agricultural Workers held at Memphis, Tenn., in February 1942, abstracts of which are given, are: Internal Parasites of Cattle, by L. E. Swanson (p. 90) (Fla. Expt. Sta.); The Relation of Calfhood Vaccination to the Control of Bang's Disease, by W. E. Cotton (pp. 109-110) (Ala. Polytech. Inst.); and Calf Diarrhea, by G. H. Wise and G. W. Anderson (pp. 110-111) (S. C. Sta.).

**The isolation of *Haplosporangium parvum* n. sp. from *Coccidioides immitis* from wild rodents—their relationship to coccidioidomycosis.** C. W. EMMONS and L. L. ASHBURN (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 46, pp. 1715-1727, pls. 4, fig. 1).

**Viability of *Brucella abortus* strain 19 in vaccine.** C. A. MITCHELL and T. MOORE (*Canad. Jour. Compar. Med. and Vet. Sci.*, 6 (1942), No. 10, pp. 292-295).—In a study of the viability of four lots of *B. abortus* strain 19 vaccine, the details of which are given in tables, low temperature proved to be the most important factor in its preservation. It appears to be a factor in drying which rapidly brings about the death of micro-organisms. Although alkali-free vials may have some advantage over ordinary vials in the preservation of viability, this advantage does not appear to be marked.

**Further experiments on accessory growth factor requirements of the *Brucella* group.** S. A. KOSER and M. H. WRIGHT (*Jour. Infect. Diseases*, 71 (1942), No. 1, pp. 86-88).—The findings reported confirm the earlier conclusion of Koser et al. (*E. S. R.*, 87, p. 109) that biotin is needed for certain *Brucella* cultures. Both pure biotin and biotin methyl ester replaced the growth-promoting property of biotin concentrate. Extremely small amounts of pure biotin supported growth; 0.0001  $\mu$ g. per cubic centimeter of medium produced about 90 percent of maximum growth, 0.00001  $\mu$ g. supported approximately half maximum, and 0.000003  $\mu$ g. was sufficient for light growth. The cultures were carried through successive transplants in the presence of 0.00001  $\mu$ g. per cubic centimeter of biotin or biotin methyl ester in the presence of larger quantities of nicotinamide, pantothenic acid, and thiamin. The pyrimidine but not the thiazole component of thiamin was required for all seven of the *Brucella* cultures.

**Immunity in brucellosis.** I. F. HUDDLESON. (*Mich. Expt. Sta.*). (*Bact. Rev.*, 6 (1942), No. 2, pp. 111-142).—This is a review, the principal purpose of which is to bring together many of the data that are related directly or indirectly to the state of active immunity to brucellosis in animals and man, to critically analyze the data as to their significance, and to point out the nature of the immunity. In summary, it is shown that in the bovine there appear to be two types of immunity, (1) a so-called "natural immunity" that functions in young animals up to or near the beginning of ovulation and (2) an acquired immunity which usually develops in unbred heifers and cows, requiring for its stimulus the presence of live organisms in the body or the injection of a labile immunogenic constituent of the bacterial cell. When virulent organisms enter the body of young animals under natural conditions or are injected in small numbers they remain for only a short time and cause little, if any, reaction on the part of the tissues. Only when large numbers of organisms are injected is sufficient reaction provoked to cause the appearance of serum antibodies in a high titer, and even then such antibodies persist for only a short time. A large percentage of normal nonpregnant heifers and cows when exposed to *Brucella* infective material instead of becoming actively infected develop a high degree of active immunity against subsequent exposures. From the small amount of data now available it would appear that the immunity acquired through the infective process persists for more than 5 yr.

"From the facts now available it may be stated categorically that the possibility of animals and human beings acquiring an active immunity to brucellosis through infection is no longer a hypothesis but a demonstrated fact. There is now conclusive proof that an active immunity can be established in adult cattle against brucellosis by infecting them as calves with live *B. abortus*, the vaccine being prepared from a culture of low virulence. The duration of the immunity produced in this manner has not been determined conclusively. Al-

though it seems highly probable that human beings could be immunized against brucellosis, there is up to the present time no convincing proof that an agent for this purpose has been developed. The possibility of an active immunity occurring in swine to *B. suis*, the infecting species, has not been considered in this review due to the fact that no information is available. Very little is known even about the course of the disease under natural conditions. It has long been recognized that swine brucellosis is an important economic disease, and that the infected hog is a reservoir from which the disease is acquired by human beings and other animals. The well-planned research programs on swine brucellosis now being undertaken at Federal and State experiment stations, if continued, should furnish information on the course of the disease and its immunological aspects that is now so badly needed.

"Since there are three known species of *Brucella*, and each may infect species of animals other than the one in which each is commonly found, it would seem essential to the successful application of measures to control the disease to know whether recovery from an attack of one species of *Brucella*, or vaccinal immunization with one species, will afford protection against the other species. In the case of human beings it has been observed repeatedly in many laboratories that those who have developed an immunity as a result of a clinical or subclinical infection with one species may freely work with the others without becoming infected. This observation has been made so many times in several laboratories that it now seems certain that an immunity which is produced by one species will protect against an infection by the other two. There are also experimental data which show that the guinea pig can be immunized against *B. abortus* infection by treatment with the crushed cell fraction derived from *B. suis* as well as from *B. abortus*."

A four-page list of references to the literature cited is included.

**In vitro studies of sulfonamide action on organisms of the *Brucella* group and the counteracting effect of para-aminobenzoic acid.** B. WISE (*Jour. Pharmacol. and Expt. Ther.*, 76 (1942), No. 2, pp. 156-160, figs. 3).—"Comparison of the bacteriostatic action of sulfathiazole, sulfadiazine, and sulfaguanidine on seven *Brucella* strains has shown sulfathiazole and sulfadiazine to have almost the same effect. The bacteriostatic effect of sulfaguanidine is more variable and frequently much less marked than that of the other drugs. Sulfathiazole and sulfadiazine in increasing concentrations above 2.5 mg. percent exhibit very small or no differences in bacteriostatic action, whereas the bacteriostatic effect of sulfaguanidine frequently varies directly with the drug concentration. *p*-Aminobenzoic acid in concentrations of 0.1 and 1.0 mg. percent partially or almost completely inhibits the action of sulfathiazole. Organisms exposed to the action of sulfathiazole for 48 hr., then explanted to drug-free broth, show a continued inhibition of growth which is not due to 'carry-over' of sulfathiazole in the explants. This persisting inhibitory effect is counteracted by *p*-aminobenzoic acid."

**An infectious agent from cases of atypical pneumonia apparently transmissible to cotton rats.** M. D. EATON, G. MEIKELJOHN, W. VANIERICK, and J. C. TALBOT (*Science*, 96 (1942), No. 2501, pp. 518-519).

**Studies in the epidemiology of Q fever.**—X, The transmission of Q fever by the tick *Ixodes holocyclus*, with notes on tick-paralysis in bandicoots, D. J. W. SMITH (*Austral. Jour. Expt. Biol. and Med. Sci.*, 20 (1942), No. 3, pp. 213-217).—In this further contribution (*E. S. R.*, 88, p. 24, 1. *holocyclus* Neuma. was found to be a potential vector of Q fever, larval, nymphal, and adult ticks having been infected experimentally by feeding on infected laboratory animals. The virus was passed from larvae to nymphs and from nymphs to adults, but

not to their progeny. An infected adult tick infected a bandlecoot upon which it fed.

**A description of an unusual *Salmonella* type, with special reference to the evolution of *Salmonella* species,** P. R. EDWARDS and D. W. BRUNER (Ky. Expt. Sta.). (*Jour. Bact.*, 44 (1942), No. 3, pp. 289-300).—Description is given of a new *Salmonella* type, *S. salinatis*. The antigenic formula for this type is IV, XII . . . : d, c, h - d, c, n, z<sub>15</sub>. Through cultivation of *S. salinatis* in semi-solid agar containing agglutinating serum for *Eberthella typhosa*, an organism having the antigenic formula IV, XII . . . : c, h - c, n, z<sub>15</sub> was isolated. The latter is biochemically and serologically indistinguishable from the Sandiego type. The bearing of these observations, and of previous experiments on induced variation, on White's theory of *Salmonella* phylogeny is discussed.

**Observations on the somatic antigens of *Salmonella cholerae-suis* var. kuzendorf,** J. T. HAYSTON (*Austral. Vet. Jour.*, 18 (1942), No. 4, pp. 172-174).

**Prevention and treatment of agranulocytosis and leukopenia in rats given sulfanilylguanidine or succinyl sulfathiazole in purified diets,** S. S. SPICER, F. S. DAFT, W. H. SEBELL, and L. L. ASHBURN (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 42, pp. 1559-1566, fig. 1).—In experimental work rats given sulfaguanidine (sulfanilylguanidine) or sulfasuxidine (succinyl sulfathiazole) in purified diets developed an agranulocytosis, a leukopenia, and a hypocellularity of bone marrow. This blood dyscrasia can largely be prevented or successfully treated with whole dried liver or with certain liver extracts. A list is given of 21 references to the literature cited.

**Quantitative determination of the bacteriostatic effect of the sulfonamide drugs on pneumococci,** C. M. MACLEOD and G. S. MIRICK (*Jour. Bact.*, 44 (1942), No. 3, pp. 277-287).

**Derivatives of dithiocarbamic acid as pesticides,** W. H. TISDALE and A. L. FLENNER (*Indus. and Engin. Chem.*, 34 (1942), No. 4, pp. 501-502).

**Stock-poisoning plants of California,** A. W. SAMPSON and H. E. MALMSTEN (*California Sta. Bul.* 593, rev. (1942), pp. 90, pls. 3, figs. 20).—A revised edition of this bulletin (E. S. R., 74, p. 396).

**The poison plants of New South Wales,** E. HURST (*Sydney: Snelling Pty. Works Pty.*, 1942, pp. XIV+498, [figs. 27]).—This work was compiled under the direction of the Poison Plants Committee of New South Wales. It is presented with a bibliography of 36 pages and a glossary of botanical and medical terms.

**Tung tree (*Aleurites fordii* Hemsl.) foliage poisoning of cattle,** D. A. SANDERS, M. W. EMMEL, and L. E. SWANSON (*Florida Sta. Bul.* 376 (1942), pp. 8, fig. 1).—Following a brief review of the literature, field observations on the toxicity of tung tree foliage, three experimental observations on tung tree foliage and one on castor-bean plant, and the microscopic pathology are considered. The work was projected following a loss in November 1941 of 14 purebred Hereford and Aberdeen-Angus cattle in a herd of 30 animals at pasture after they had eaten discarded green and partly cured leaf foliage from nursery stock of the tung tree. Several of the animals died within 3 to 4 days after onset of symptoms, and animals that survived for a longer period continued to refuse feed, developed a seropurulent nasal discharge, and drooled saliva. Further symptoms consisted of dyspnea, reddening and cracking of the skin of the muzzle, gritting of the teeth, drooped ears, and progressive emaciation. Affected animals remained lying down most of the time and showed considerable distress. Watery feces containing blood soiled the vulva, tail, and buttocks. All 14 animals succumbed within 4 weeks. A feeding experiment led to the conclusion that the castor-bean plant was not responsible for the losses which oc-

curred in this herd. It was shown in feeding experiments that even a small quantity of tung tree foliage is highly toxic and fatal to cattle.

**Some factors influencing the toxicity of selenium,** A. L. MOXON and H. D. ANDERSON. (S. Dak. Expt. Sta.). (*Amer. Chem. Soc. Mtg.*, 103 (1942), *Abs. Papers*, pp. 4A-5A).—Brief reference is made to the results of studies on the influence of various elements and compounds upon the toxicity of selenium that have extended over a period of several years. Using albino rats it was found that arsenic as sodium arsenite when fed at the rate of 5 p. p. m. in drinking water would counteract the toxicity of a diet containing 18 p. p. m. of selenium, and 10 p. p. m. of arsenic in the drinking water gave complete protection with this diet. Sodium arsenite was equally effective. The arsenic sulfides,  $\text{AsS}_2$  and  $\text{AsS}_3$ , were ineffective. Sodium arsenite was effective against selenium as seleniferous wheat, sodium selenite, and selenium-cystine. A diet containing from 12 to 15 p. p. m. of selenium caused death of dogs within 3 to 4 mo. Hatchability of eggs laid by hens fed a seleniferous ration is greatly reduced due to the high incidence of monstrosities. Arsenic used (25 p. p. m. in the salt) for cattle on a seleniferous ranch has shown promise as a preventive measure for the "alkali disease" or selenium poisoning in cattle in seleniferous areas. Certain proteins and protein concentrates have proved to be effective in preventing the toxic effects of seleniferous feeds. There are, however, species differences in the reactions of the proteins. Crude casein will protect rats against the toxic effects of selenium but will not protect dogs against the same amount or even lower amounts of selenium. Linseed meal has been effective against selenium poisoning in both rats and dogs. Fish meal, meat meal, and tankage appear to increase the toxicity of selenium.

**Some effects of copper intake on cattle,** W. M. NEAL. (Fla. Expt. Sta.). (*Amer. Chem. Soc. Mtg.*, 103 (1942), *Abs. Papers*, p. 7A).—Symptoms of copper deficiency in cattle have been found to include anemia, diarrhea, loss of appetite, and depigmentation of the hair. Not all affected animals are anemic. Less than 1.5 to 3.0 p. p. m. of copper in forage dry matter will cause deficiency, although deficiency may occur with several times this amount.

**Blackleg in cattle,** H. WELCH (*Montana Sta. Cir.* 167 (1942), pp. 6, figs. 3).—A revision of Circular 144 (E. S. R., 72, p. 693).

**Abscesses due to infection with *Corynebacterium pyogenes* in bovines,** J. G. H. HOEBEN (*Austral. Vet. Jour.*, 18 (1942), No. 5, pp. 209-211).

**An attempt to demonstrate a virus as the cause of mastitis in cattle,** L. D. BUSHNELL. (Kans. State Col.). (*Jour. Bact.*, 44 (1942), No. 3, p. 393).—The author has been unable to confirm the finding of Broadhurst, Cameron, and McLean (E. S. R., 82, p. 103) regarding a filtrable virus as the cause of mastitis in cows.

**Some new observations on the developmental cycle of the organism of bovine pleuropneumonia and related microbes,** E. KLIENEBERGER and J. SMILES (*Jour. Hyg. [London]*, 42 (1942), No. 2, pp. 110-123, pls. 4).—A study made of the growth phases of pleuropneumonia by two new methods, (1) a new fixing and staining technic and (2) a new dark-ground method, is reported upon. The life cycle of the organism of this affection and related microbes as revealed by means of both methods is described.

**The geographical distribution of bovine trichomoniasis,** B. B. MORGAN and B. A. BEACH. (Wis. Expt. Sta.). (*Vet. Med.*, 37 (1942), No. 11, pp. 459-462, figs. 3).

**Persistent foramen ovale and multiple defects of interventricular septum in a calf,** J. W. BRITTON. (Univ. Calif.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 339-341, fig. 1).

**Haemoglobinuria of calves in the south-west of Western Australia**, L. W. MAHAFFEY, H. W. BENNETTS, and A. F. FLOOD (*Austral. Vet. Jour.*, 18 (1942), No. 5, pp. 205-208).—A disease of young calves in which hemoglobinuria is the principal clinical sign is described. Although the etiology is undetermined, the disease does not appear to be infectious or to be due to an enterotoxemia or to copper poisoning.

**A "staggers" syndrome in sheep and cattle associated with grazing on *Phalaris tuberosa***, I. W. McDONALD (*Austral. Vet. Jour.*, 18 (1942), No. 5, pp. 182-189).—Account is given of the staggers syndrome in sheep and cattle produced by feeding on a restricted diet of the young growth of the perennial grass *P. tuberosa*, which has been widely used in Australia for the development of permanent pastures and has proved very valuable. The rarity of the affection contrasted with the common use of the plant is noted, but no explanation of the phenomenon is available. The disease is closely analogous to that produced by perennial ryegrass (*Lolium perenne*) and is similar in many respects to staggers due to the ingestion of several other plant species. At autopsy no pathognomonic lesions were observed. The chief abnormality noted in microscopic examinations was a degeneration of certain tracts in the spinal cord. Hemosiderosis of the kidney was a concomitant feature.

**A preliminary note on the aetiology of enzootic jaundice, toxæmic jaundice, or "yellows," of sheep in Australia**, H. E. ALBISTON, L. B. BULL, A. T. DICK, and J. C. KEAST (*Austral. Vet. Jour.*, 16 (1940), No. 6, pp. 233-243, figs. 2).—The Toxæmic Jaundice Investigation Committee has been led to conclude that toxic jaundice, which occurs mainly in enzootic form almost exclusively in British breeds of sheep or their crosses in Australia, is due to a disturbance of copper metabolism associated with high storage values for copper in the liver and a sudden mobilization of copper into the blood stream. The high storage value is possibly associated with the ingestion of food with a higher content of copper than may be found in pasture plants in the nonenzootic areas. There may be also a low efficiency in the excretion of copper, but evidence of this does not exist. Although the disease is essentially the same as copper poisoning, it is not due to excessive intake of copper through licks, drenches, or through contamination of pasture or of the water with copper.

**Investigations on contagious ophthalmia of sheep, with special attention to the epidemiology of infection by Rickettsiae conjunctivae**, W. I. B. BEVERIDGE (*Austral. Vet. Jour.*, 18 (1942), No. 4, pp. 155-164, fig. 1).

**Saving Oregon's ewes and lambs: Pregnancy disease of ewes**, O. H. MUTH, J. N. SHAW, and D. E. RICHARDS (*Oregon Sta. Cir. Inform.* 277 (1942), pp. 8).—A practical account of this nutritional disease of ewes, which results from insufficient intake of feed during the last 6 weeks of pregnancy. The nutritional requirements for its prevention are discussed. While treatment should not be depended upon for its control, the lives of some affected ewes can be saved if it is started when the first symptoms appear. It consists in the administration of 0.5 lb. of commercial sugar, corn sirup, or molasses dissolved in 1 gal. of warm water by means of a stomach tube and repeated daily until the ewe again feeds normally.

**Nodular worm disease of sheep**, M. P. SARLES and A. O. FOSTER (*U. S. Dept. Agr. Leaflet* 228 (1942), pp. [2]+6, figs. 4).—A practical account of nodular worm affection of sheep with directions for its control and eradication. This parasite, known as the nodular worm because it causes abscesslike swellings or nodules in the wall of the intestines and produces the condition called nodular disease, pimply gut, or knotty gut, is responsible for serious losses to the meat industry and to the sheep raiser. The formation of nodules and gritty masses in the intestinal

wall causes direct loss by rendering the intestines unfit for sausage casings or for the manufacture of surgical sutures. It is pointed out that such losses are doubly serious because of the greatly increased demand for all these products and difficulties in obtaining them from other sheep-raising countries. The practical prevention of this disease can be achieved in great measure by timely treatment with phenothiazine in conjunction with pasture hygiene and general sanitation.

**Enzootic ataxia of lambs in South Australia**, I. W. McDONALD (*Austral. Vet. Jour.*, 18 (1942), No. 4, pp. 165-172).

**The incidence, prevalence, and distribution of the helminths infesting the lungs and alimentary tract of the pig in Queensland**, F. H. S. ROBERTS (*Austral. Vet. Jour.*, 16 (1940), No. 6, pp. 259-266).—Twenty species of helminths representing 17 genera are listed as parasites of pigs in Queensland. Of a total of 243 pigs examined, 185 were infested, yielding 14 different species of helminths. The incidence and prevalence of each of these were determined.

**Further Salmonella infections in pigs and acute paratyphoid septicaemia in horses**, D. F. STEWART (*Austral. Vet. Jour.*, 16 (1940), No. 6, pp. 266-267).

**Sulfaguanidine chemotherapy in enteric conditions of swine** (*North Amer. Vet.*, 23 (1942), No. 10, pp. 653, 670).

**The anomaly of a normal Duke's and a very prolonged saline bleeding time in swine suffering from an inherited bleeding disease**, E. T. MERIZ. (Mo. Expt. Sta.). (*Amer. Jour. Physiol.*, 136 (1942), No. 3, pp. 360-362, fig. 1).—The saline bleeding time in swine suffering from an inherited bleeding disease was found to be about six times the normal value. In contrast, Duke's bleeding time is consistently normal.

**Grass sickness in horses: A review of the present knowledge of the disease, with particular reference to the nature of the causal agent**, J. R. GREIG (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 54 (1942), pp. 1-27).

**Estudios de inmunidad cruzada entre el virus de la encefalomiелitis equina de Venezuela y los virus encefalomiелiticos norteamericanos este y oeste y el Argentino** (Cross-immunity studies between Venezuelan equine encephalomyelitis virus and eastern, western, and Argentine virus, V. KUBES and A. DIAMANTE (*Bol. Inst. Invest. Vet. [Venezuela]*, 1 (1942), No. 2, pp. [1]+49-79; *Eng. abs.*, pp. 77-79; *Eng. abs. also in Canad. Jour. Compar. Med. and Vet. Sci.*, 6 (1942), No. 12, pp. 357-359).—The studies here reported have led to the conclusion that the virus of Venezuelan equine encephalomyelitis is a sui generis immunological entity bearing no specific antigenic relationship to eastern, western, or Argentine virus.

**Studies with equine streptococci, II-IV**, P. L. BAZELEY (*Austral. Vet. Jour.*, 16 (1940), No. 6, pp. 243-259, figs. 2; 18 (1942), Nos. 4, pp. 141-155; 5, pp. 189-194).—These studies are in continuation of that noted (*E. S. R.*, 84, p. 249).

II. *Experimental immunity to Str[eptococcus] equi* (pp. 243-259).—In a search of the literature little evidence was found that vaccines made from *S. equi*, the causative agent of strangles in horses, possessed immunizing powers when tested in small laboratory animals. When mice were used by the author as test animals young culture vaccines of *S. equi* were shown to possess immunizing powers greatly superior to the older culture products, although the latter were not entirely lacking in this respect. Useful immunizing vaccines were found to consist mainly of capsulated organisms, indicating that the immunoantigen is associated with the capsular structure of *S. equi*. These vaccines appeared also to possess a strong repulsive surface charge on most organisms which was responsible for a slow rate of sedimentation. Poor immunizing vaccines were found to sediment rapidly. The exposure to heat at 56° C. necessary to kill vaccines of *S. equi* proved to be as small as 0.9 min. when a special apparatus was used. The advantage from

such short exposures seems to be negligible compared with a simple glass flask or test-tube technic. Some extra exposure above minimal lethal heat is also possible without severe damage to the immunointigen.

III. *Vaccination against strangles* (pp. 141-155).—In continuation of this work, certain vaccines previously in use against strangles were found to lack immunizing power. In the first of two field trials conducted with a view to determining the possibility of developing a vaccine to protect horses against strangles the results, while inconclusive, were in favor of a cautiously killed young culture vaccine. When such a vaccine was tested in larger groups of horses, definite immunizing powers were revealed which had a strong influence on the course of strangles epidemics in the regiments concerned.

IV. *Cross-immunity to Streptococcus equi* (pp. 189-194).—In tests of 32 strains of *S. equi* both for virulence in unprotected mice and in mice protected by serum prepared with a single strain definite cross-protection was shown by the univalent serum in all cases. There is considered to be strong evidence that only one immunological type of *S. equi* exists, at least in Australia. The importance of this finding in the vaccination of horses is emphasized.

Effects of phenothiazine on horses.—I, *Studies in haematology and pharmacology*, W. E. SWALES, H. B. COLLIER, and D. ALLEN (*Canad. Jour. Res.*, 20 (1942), No. 11, Sect. D, pp. 349-361, figs. 2).—In studies made on the anemia and cythemolytic icterus produced by 60- and 70- gm. doses of phenothiazine to horses weighing approximately 1,200 lb. it was shown that the continued and prolonged hemolytic effect of a single dose may be serious in a horse having a large proportion of microcytic erythrocytes. No evidence of damage to the liver was obtained, but clinical observations confirm a previous report that severe injury to the urinary system may result from a dose of 60 gm. of phenothiazine to a 1,200-lb. horse. A dose of 30 gm. removed all the stronglyloid nematodes and did not cause hemolysis. Less than half the dose could be recovered from the excreta of treated animals. The effects of phenothiazine on horses are similar to those of sulfanllamide and sulfapyridine in susceptible humans. The possibility of overstimulation of the spleen with the consequent hyperactivity causing prolonged hemolysis is mentioned.

Incidence of leptospirosis among dogs in Honolulu as determined by serological agglutination tests, J. E. ALICATA and V. BREAKS (*Jour. Wash. Acad. Sci.*, 32 (1942), No. 10, pp. 305-308).—Report is made of microscopic agglutination tests of the serums of 100 dogs from Honolulu in which fresh formalin-killed *Leptospira canicola* and *L. icterohaemorrhagiae* were used as antigens. Of these, 20 percent of the serums gave stronger agglutination reactions to *L. icterohaemorrhagiae* than to *L. canicola*, and 19 percent reacted more strongly to *L. canicola*. Leptospirae were recovered from 2 dogs suspected of having died of canicola fever. Of 500 rats examined in Honolulu, 2.6 percent were found to harbor leptospirae. This low incidence indicates little epizootiological relationship between murine and canine infections.

Distemper studies in ferrets.—VI, *Attempted control of a distemper epidemic in a ferret colony with tissue vaccines and with anti-serum*, E. A. WATSON, L. M. HEATH, and P. J. G. PLUMMER (*Canad. Jour. Compar. Med. and Vet. Sci.*, 6 (1942), No. 11, pp. 324-331).—In continuing this series (E. S. R., 88, p. 247), both tissue vaccines and antiserum protected ferrets to some extent against the natural spread of distemper provided these agents were employed individually within specific time limits after the appearance of the disease in the colony. The simultaneous use of tissue vaccine and antiserum, however, gave less protection than either of the agents applied separately at the same time periods after the beginning of the outbreak. The mortality in untreated ferrets

reached its peak between the ninth and twenty-fourth day, while that in the treated animal indicated no marked peak and was spread from the ninth to the fortieth day following treatment. Inclusion bodies as a criterion of infection could not be relied upon, since in random sampling among affected ferrets, seven of which were treated and seven untreated, these manifestations were present in only 42.8 and 14.2 percent, respectively, of the animals examined.

**Soil temperatures and soil moisture as factors governing the seasonal incidence of certain parasitic worms**, R. O. CHRISTENSON and H. H. CREEL. (Ala. Polytech. Inst.). (*Jour. Tenn. Acad. Sci.*, 17 (1942), No. 4, p. 341).—An abstract of a contribution presented at the annual meeting of the Association of Southeastern Biologists in April 1942. Autopsies of 165 chickens during the 12 mo. of 1941 revealed 15,969 intestinal parasites, largely *Heterakis gallinae* and *Ascaridia galli*. There was a considerable variation in the temperature and moisture characteristics of the various soil types, but only for short periods in May and June did the soil moisture attain sufficiently low levels to appreciably affect the survival of parasite eggs.

**A survey of the incidence, distribution, and prevalence of the helminth parasites of the domestic fowl in Queensland**, M. BROADBENT (*Austral. Vet. Jour.*, 18 (1942), No. 5, pp. 200-204).—The incidence and prevalence of 12 helminths of the domestic fowl found in nine districts in Queensland are reported upon.

**Coccidiosis of poultry**, C. D. LEE. (Iowa State Col.). (*North Amer. Vet.*, 23 (1942), No. 7, pp. 458-460).

**Influence of sulfaguanidine on acquired resistance in chickens to cecal coccidiosis**, R. W. ALLEN and M. M. FARR. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 5, pp. 464-465).—The authors' findings from feeding experiments involving 267 11-day-old Rhode Island Red chickens indicate that a 0.5-percent concentration of sulfaguanidine in the mash is sufficiently high to be of value as a prophylactic for cecal coccidiosis yet not so high as to interfere with the acquirement of an effective resistance to the disease.

**Sage grouse coccidiosis not transmissible to chickens**, R. F. HONESS. (Wyo. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, p. 560).—An outbreak of coccidiosis among the sage grouse (*Centrocercus urophasianus*) in Fremont County, Wyo., led to cross-infection experiments. Not a single case of coccidiosis developed in either the experimental domestic chickens or in the control chickens during the 3 yr. under way. Two groups of experimental chickens were later fed viable oocysts from mixed infections in the domestic chicken, all of which developed severe coccidiosis and many succumbed. The author was led to conclude that coccidiosis is not carried to domestic chickens by the sage grouse, and that the infection in the sage grouse is not brought about by contact with infected domestic birds.

**Effect of quinine upon the course of fowl-pox infection in the chick**, B. H. ROBBINS (*Jour. Pharmacol. and Expt. Ther.*, 76 (1942), No. 1, pp. 57-63, figs. 2).—Report is made of the effect of quinine in altering the normal course of development of experimental fowl pox infection in the chick.

**Experiments with X-rays on the roles of lymphocytes and body temperatures in the resistance of chicks to *Salmonella pullorum***, J. C. SCHOLES. (Cornell Univ.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 561-565, fig. 1).—Report is made of an experiment conducted to determine the effect of exposure of 6-day-old chicks to 360γ units of X-ray. The body temperatures of exposed chicks brooded at 28° C. were significantly lower than those of control chicks on the second, third, and fourth days following exposure. The body temperatures of chicks brooded at 35° were only slightly affected. There were indications of injury to intes-

tinal mucosa and to the liver. It is suggested that tissue injury may have been responsible for the lowered resistance of chicks to *S. pullorum* following X-ray treatment observed by Roberts, Severens, and Card (E. S. R., 82, p. 466). The relation between body temperature and resistance to *S. pullorum* is discussed, and it is concluded that resistance more likely depends upon temperature differences than upon differences in the number of lymphocytes in the blood.

**Sanitation important in controlling paratyphoid infection of turkeys** (*North Carolina Sta. Rpt. 1941, pp. 58-59*).—Reference is made to the progress of work which has emphasized the importance of sanitation in the handling of breeder turkeys and suggests a method for the eradication of paratyphoid disease through the detection of breeder carriers. That it is possible to control the disease in its worst phase by incubator fumigation is indicated, since the infection is found on the eggshells. It is deemed essentially an intestinal rather than a blood disease, and studies on 80 artificially infected poults, as well as survivors of diseased poults, indicated that infected poults do not become chronic carriers.

**Clinical pathology of trichomoniasis of the lower digestive tract of turkeys**, E. A. ALLEN and M. W. OLSEN. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 5, p. 464).

**Trichomoniasis of the upper digestive tract of domesticated birds**, L. D. BUSHNELL. (Kans. State Col.). (*Poultry Sci.*, 21 (1942), No. 5, pp. 466-467).

## AGRICULTURAL ENGINEERING

**The principles of field drainage**, H. H. NICHOLSON (*Cambridge, Eng.: Univ. Press; New York: Macmillan Co., 1942, pp. XI+165, pls. 12, figs. 29*).—The author disclaims any attempt to deal with the technicalities of surveying, engineering, or even the drainer's art. His aim has been, rather, to draw attention to the fundamentals of the subject, to present "a philosophy of draining," and to deal with the factors involved and the way in which they influence events in the soil.

The contents include chapters on former neglect of drainage work, measures of government assistance; the history of field-draining developments in Great Britain; the moisture properties of soil, the incidence of drainage; percolation, permeability, the water table, the special case of clay land; drainage conditions in the field (soil and site factors, the main types of drainage circumstances); the use of published maps in field-drainage work; the investigation of field-drainage problems; ditches; tile draining, methods and principles, renovation of old systems, design and materials; mole draining, suitable soils, details, causes of failure, machinery, procedure; the way in which drains work, rates of flow from outfalls; drainage of airdromes, sports grounds and field fortifications; field drainage, river flow and floods; and field drainage, present position and progress.

**Stratified flow in reservoirs and its use in prevention of silting**, H. S. BELL (U. S. Dept. Agr., Misc. Pub. 491 (1942), pp. II+46, figs. 40).—Stratified flows or density currents are described, and their behavior in natural and artificial lakes is discussed. Some striking photographs of laboratory demonstrations of such under- and interstreams are reproduced. Uses of such flows for the removal of suspended material from reservoirs before it settles out and for the similar removal of underlying layers of salty water are suggested.

**Removal of fluorides from public water supplies**, R. C. GOODWIN and J. B. LITTON (*Indus. and Engin. Chem.*, 33 (1941), No. 8, pp. 1046-1048, figs. 3).—Pilot plant experiments on the use of a mixture of calcium phosphate monohydrate any hydroxy apatite are reported. Water containing approximately 5 p. p. m. of fluorine was reduced to an average fluorine content of 0.42 p. p. m. The

purifying material can be regenerated by treatment with sodium hydroxide, washing, and neutralizing with carbon dioxide.

**How to increase farm production with reduced man power, D. A. MILLIGAN** (*Agr. Engin.*, 23 (1942), No. 10, pp. 309-311, figs. 2).—The author lists as means for increasing farm production with reduced man power: Reduction of man labor per crop unit; reduction of number of operations performed in the producing of crops; working more hours per day and more days per week, per month, and per year; a well-organized and diversified system of crop and livestock production with a distributed labor requirement; and increasing the yield maxima. Under the first two headings, operating the tractor with its largest practicable load, especially for the purpose of combining two operations into one, is one of the principal suggestions offered, but poor preparation of seedbed to effect a saving of labor is specifically condemned. In connection with the increase of number of working hours per man, the elimination of tiring mechanical noise, discomfort due to unnecessary jar, heat exposure, and exhaust fume inhalation is emphasized, together with some device facilitating the work itself. Concerning the fourth point, it is noted that livestock production is ideally adapted to the distribution and leveling of labor requirements, that diversified crops and production reduce the hazard of crop failures, and that the proper diversification of crops and livestock may eliminate harvesting altogether. With reference to the raising of the yield maxima, it is urged that farmers avoid attempting acreage greater than they can handle with power and equipment sufficient to prepare the seedbed at the proper time, and that in adverse seasons it is better to leave certain of the land idle than to prepare, seed, plant, and tend poorly a larger acreage which, under those conditions, may result in crop failure or low yields and poor quality.

**The integration of farm equipment into the war effort, F. J. ZINK** (*Agr. Engin.*, 23 (1942), No. 10, pp. 317-320, figs. 3).—This is a general discussion presenting, with numerical data, various questions raised by the required increase in production of food, fiber, and oil crops as problems of the agricultural engineer. The need for avoiding the errors of the former war, as that of bad land use and other mistakes leading to economic upset, is emphasized. Other points demanding the attention of the engineer are the questions whether or not increased numbers of workers drawn from the farm population and from other sources can meet the need without increased supplies of labor-saving equipment, to what extent joint use of mechanical equipment can be practiced before the vanishing point of increasing capacity is reached, to what extent custom operation of machines will be a practicable solution of machine shortages, how much machine power can be replaced by animal power, etc.

**Changes in hay handling methods and equipment, A. E. W. JOHNSON** (*Agr. Engin.*, 23 (1942), No. 10, pp. 325, 327, fig. 1).—The author briefly outlines mechanical equipment development since 1918, indicating that diversity of land type and of acreages will continue to require a wide variety of equipment. The introduction of new pasture grasses, some of which will be cut for hay, may bring new harvesting problems. Of the new hay harvesting machines, the recent development of the forage harvester seems to offer considerable promise. Although some hay will be necessary when grass silage is fed, the forage harvester can be used for this type of haying. A mower, side-delivery rake, and forage harvester equipped with pick-up attachment can be used conveniently and economically. The same wagons and blower as used for green crops provide the means for hauling and elevating the chopped hay into the barn. Recent efforts in the development of lighter and more economically operated pick-up balers, likewise, are

extremely promising and will probably be increasingly attractive to many individual users.

**Once-over cotton planter and fertilizer distributor developed for the cotton farmer.** (Coop. U. S. D. A.). (*North Carolina Sta. Rpt. 1941, pp 21-22, fig. 1*).—A brief account of this combination planter and distributor.

**Developments in fruit dehydrator design,** R. GUILLOU. (Univ. Calif.). (*Agr. Engin., 23 (1942), No. 10, pp. 313-316, figs. 9*).—The author points out that dehydrator design thus far has had to depend upon assumptions, based upon accepted practice, with reference both to tunnel dimensions and to drying time, and that "so long as performance of a design is based on an assumed drying time, there can be no intelligent determination of the effect of air velocity, temperature, or other factors on capacity of the unit." He briefly describes measurements of drying rates of prunes carried on for the past two seasons in a small wind tunnel provided with means for controlling and measuring the temperature, velocity, and humidity of the air to obtain quantitative relations among dehydrator conditions, drying rates, and quality of product. The drying section holds 400 prunes, of which 100 are a source of samples to be used as a check on moisture content. The remaining 300 are weighed hourly to determine drying rate and furnish samples for final determination of moisture content and appraisal of quality. By analyses of these data he deduces empirical expressions for drying rate in terms of the variables involved and separately develops the optimum value for each of controllable variables. The results are embodied in a design believed to provide the closest practicable approach to the optimum values. The author holds that a similar method could be applied for the designing of equipment for any other similarly dehydrated product.

**Remodeled barns help meet wartime needs,** J. M. ANDERSON (*Agr. Engin., 23 (1942), No. 10, pp. 326-327, figs. 2*).—The author finds inadequate or improperly designed footings to be one of the common causes of deterioration, the footings being often not deep enough to prevent frost heaving or having a spread insufficient to provide against settling, with the result that the building is subject to leaning, sagging, or bulging. The remedy here discussed consists in putting in new concrete footings and foundation walls and replacing the side walls up to the mow floor with a hollow tile. The author finds that the most common rebuilding procedure is to jack up one-half of the barn at a time. By jackscrews one-half of the building can be easily raised to a height giving sufficient clearance for a mason to complete the new wall.

**Dairy barn construction** (*Vermont Sta. Bul. 495 (1942), p. 24*).—Dairy barn construction work by H. B. Ellenberger included analysis of temperature data for measuring the thermal efficiency of sundry insulating materials located within the side walls and ceiling of a one-story dairy barn, making hygrothermograph records which show a rather uniform temperature throughout the winter in a one-story dairy barn ventilated with exhaust fans but widely fluctuating in percentage of relative humidity, moisture gage readings on the wooden sheathing of the side walls and ceiling, etc.

**Store food for the winter** (*West Virginia Sta. Cir. WS 6 (1942), pp. [8], figs. 2*).—Improvised storage arrangements suitable, respectively, for fresh fruits and vegetables, for dried fruits and vegetables, and for canned foods are briefly discussed. Heat treatment designed to prevent insect damage to dried material which is to be held in closed containers is described, and the need for both the heating and the exclusion of air is emphasized. The insulating value of various thicknesses of commonly available insulating materials is compared to that of 1-in. corkboard or of granulated cork. Ground storage, trenches, pits, and mounds are among the expedients considered.

**Ventilation of ear corn in metal cribs**, G. R. SHIER and R. C. MILLER (*Ohio Sta. Bimo. Bul.* 219 (1942), pp. 171-177, figs. 7).—The construction of simple horizontal ventilating flues with side walls of 2- by 4- or 2- by 6-in. lumber is described, together with conversion of the ordinary suction cowl ventilator by the reversal and enlargement of the directing vane. In tests carried out in 1940 and 1941, the horizontal flue systems tried were sufficiently effective to prevent mold almost entirely. The pressure cowl ventilators made by reversing the suction cowl type were also effective, but the suction cowl unaltered was not effective enough to prevent spoilage.

**Methods of moisture drainage from silos**, C. K. OTIS. (Minn. Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 10, pp. 321-323, figs. 8).—In order to determine (1) the amount and the rate of flow of juice to be expected under various conditions, (2) the manner in which the juice leaks from the silo, (3) the chemical composition of the juice drained off, and (4) a method of construction that will insure a minimum of leakage, a 14- by 45-ft. silo was especially constructed and equipped and compared with a silo of the same size already in use for alfalfa silage and equipped with a gravel bottom and a side wall drain to a height of 20 ft. on each side of the doors. The wall of the experimental silo was divided into four quadrants, two of which were plain walls similar to those of a conventional concrete stave silo and the other two equipped with sidewall drains. The wall drainage was collected from each quadrant separately by means of a trough, cast in the top of the foundation wall, which carried the juice to an outlet pipe and thus to a pail outside where the liquid was measured. The concrete floor was equipped with a drain trough, running across the diameter of the silo and covered with concrete plates fitted loosely to provide easy passage for the juice. Of the two types of sidewall drains used, one consisted of continuous grooves cast into the staves. These grooves were  $\frac{1}{4}$  in. deep and  $\frac{1}{4}$  in. wide, about 1 in. apart, and extended to the top of the silo. The drains used on the other wall consisted of perforated metal ducts inserted into grooves cast into the staves, placed 10 in. apart, and extend 25 ft. upward. Portholes 4.5 in. in diameter at 5-ft. intervals were used for taking horizontal samples for density determinations and smaller portholes for temperature measurements and observations. Drainage data, juice analysis figures, and estimates of the loss of nutrients in the drained-off juice are tabulated, and variations of the density of the silage mass with depth and distance from the side walls are graphically shown. With reference to the cause and prevention of leakage, the density of the mass was found to increase with depth to a degree causing the descending juice to build up a head, whereas the density decreased from center to side wall, allowing the juice a relatively easy lateral flow. The principle of sidewall drainage was therefore concluded to be sound.

**A wood-burning conversion unit for household furnaces**, H. W. HICOCK, A. R. OLSON, and L. E. SEELEY (*Connecticut [New Haven] Sta. Bul.* 463 (1942), pp. 593-614, figs. 5).—The inefficient burning of wood in the average household furnace because of the limited capacity of the firebox and failure to provide sufficient room for the gases to burn out, with resulting high chimney losses and fouling of heating surfaces and flues with tar, has been overcome by a conversion unit of radically improved design. This unit provides, essentially, a fuel chamber, a combustion tunnel, a built-in air duct system, and a draft slide to control the air supply. With the exception of the cast-iron feed door and frame, construction is entirely of noncritical materials. These materials comprise firebrick, a few soft, high-temperature insulating bricks, wood parts for the draft slide, concrete parts to be cast in place, etc. The successive steps in the construction are fully described and are clearly illustrated in diagrams, detailed

drawings, sections, and an isometric drawing of the completed unit with parts cut away to show the interior. Directions for securing convenient operation and efficient performance are included.

Tests of the new device showed that it will operate satisfactorily either at low or at high combustion rates. Either seasoned or freshly cut wood was satisfactorily used. At low rates, when air is admitted through one duct only, the unit functions like a charcoal kiln, the wood being slowly reduced to charcoal with a shrinkage of from 30 to 50 percent in volume. By continued use of one duct only the charcoal will also be consumed. Combustion of charcoal under these conditions will be very slow and refueling will probably not be needed oftener than every 24-30 hr. At high rates two main ducts, as well as a secondary air duct, are fully open and air enters the fuel chamber at four points. Rapid combustion takes place, and after several hours a glow is visible near the combustion tunnel and over the air inlets into the fuel chamber. Charcoal is apparently burned as fast as it is formed and, when the fuel mass is almost consumed, will be found only along the chamber side walls. A full charge of wood (about 0.1 cord) will last for only from 6 to 8 hr. under these conditions. This rate of fuel consumption will be necessary only in the most severe weather.

## AGRICULTURAL ECONOMICS

[**Proceedings of the fifteenth annual meeting of the Western Farm Economics Association**] (*West. Farm Econ. Assoc. Proc.*, 15 (1942), pp. 170, figs. 4).—At this meeting, held at Palo Alto, Calif., June 24-26, 1942, the principal papers, with discussions, were as follows: Presidential Address, by R. R. Renne (pp. 11-12) (Mont. State Col.); Current and Prospective Problems of Western Agriculture Accompanying the War, by H. R. Wellman (pp. 13-21); Western Agriculture in the Last War, by E. F. Dummer (pp. 22-29) (Wash. State Col.); Symposium on Western Agriculture in the Post-War World, by J. S. Davis (pp. 33-34); Problems and Policies Facing the Range Livestock Industry, by A. F. Vass (pp. 35-39) (Univ. Wyo.); Western Agriculture After the War, With Special Reference to Fresh, Canned, and Dried Fruits, by F. R. Wilcox (pp. 40-42); The Use of Uncultivated Lands in Western United States, by S. N. Wyckoff (pp. 43-45) (U. S. D. A.); Adjustment of Western Agriculture to the Unfolding Economic Objectives of the War, by H. M. Creech (pp. 46-48); The Effect of Post War Reclamation Expansion on the Agriculture of the West, by C. H. West (pp. 49-50) (U. S. D. A.); Trends in Agricultural Cooperation, by E. A. Stokdyk (pp. 51-62); Agricultural Output Control in War Time, by S. Enke (pp. 63-72) (Mont. State Col.); Agricultural Price Policies in War Time, by H. Working (pp. 73-85); Is Federal Crop Insurance Worth Its Cost? by J. C. Clendenin (pp. 95-104) (Univ. Calif.); Public Control of the Marketing of Fluid Milk in California, by W. J. Kuhrt (pp. 105-110); Merchandise Availability on Typical Rural Towns, by D. E. Faville (pp. 111-115); Farm Management Problems Associated With Attainment of Production Goals, by N. O. Thompson (pp. 118-124) (Univ. Ariz.); What Should Be Done About Farm Tenancy (The Problem at the National Level), by J. Ackerman (pp. 127-131); Economic Planning in a Democratic Society, by D. F. Pegrum (pp. 134-145), and Problems in Planning Wartime Agriculture, by J. M. Tinley (pp. 146-152) (both Univ. Calif.).

[**Investigations in agricultural economics at the Mississippi Station**] (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 11, pp. 1, 2, 3-6, 7, 8, figs. 6).—A short article, Profitable Year for Truck Crops in Copiah County, by M. Guin (p. 2), gives data as to average receipts, expenses, investment, prices received, labor income, etc., for 80 truck farms in 1941. Another short article, by F. J. Welch

(p. 8) (coop. U. S. D. A. et al.), discusses the studies on farm labor needs, production goals, land tenure in the Yazoo-Mississippi Delta, farm adjustments, and the Copiah truck area, and also the social effects of government purchase of land in Lafayette County affected by the construction of the Sardis Dam and Reservoir. A third article, Beef Calf Production in Mississippi, by R. H. Means, A. E. Cullison, E. B. Ferris, and S. P. Crockett (pp. 1, 3-6, 7), discusses beef production under conditions of minimum-for-efficiency investments in pasture and breeding herds. It is based on the findings of studies at the central station at State College, the Holly Springs and Natchez Substations, and the Oktibbeha-Winston land-use research area in the east central part of the State.

[Investigations in agricultural economics by the North Carolina Station] (*North Carolina Sta. Rpt. 1941*, pp. 67-68).—Brief findings are included as to the rate at which delinquent farm taxes are paid, the improvement of low incomes on cotton farms (coop. U. S. D. A.), costs of ginning cotton, and costs of operating tobacco warehouses.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul. 219* (1942), pp. 178-180).—An article, Sources of Revenue of Ohio Governments, by J. D. Thewlis (pp. 178-179), includes and briefly discusses a table showing by selected years, 1917-40, the total revenue receipts for State and local governments and the percentage distribution by source. The table of index numbers of production, prices, and income, by J. I. Falconer (p. 180) (E. S. R., 88, p. 394), is brought down through August 1941.

Area analysis and agricultural adjustments for Chase County, Kansas, W. H. PINE, M. L. OTTO, and W. H. MERZGER (*Kansas Sta., Agr. Econ. Rpt. 14* (1942), pp. [1]+13, fig. 1).—A study similar to that for Nemaha County, previously noted (E. S. R., 88, p. 397).

Farm plans for upland farms in the Bluestem Belt of Kansas, W. H. PINE (*Kansas Sta., Agr. Econ. Rpt. 15* (1942), pp. [1]+7).—Budgets prepared for seven types of organization for 320-acre upland farms in Chase County are compared.

Trends in land use and related changes in Knott County, Kentucky, 1929-1939, R. H. ALLEN and C. G. DEATON. (Coop. U. S. D. A.). (*Kentucky Sta. Bul. 428* (1942), pp. 39, figs. 4).—A field survey was made in the summer of 1940 to obtain land use and related data for a representative sample of farms comparable to those for which similar data were obtained in 1929 (E. S. R., 78, p. 433). Usable records were obtained from 316 farms, of which 127 were covered by the 1929 study. The records were analyzed to show the size of farms, tenure, land use, crop and livestock production, cash farm receipts and expenditures, outside income, family income, etc., and the changes from 1929 are discussed. The population changes and migration and the educational facilities of the county are described.

During the decade the population of the county increased 28 percent and the number of farms 36 percent, but the total land in farms decreased 5 percent. The proportions of cropped land and plowable pasture increased. Corn acreage per farm and total crop acreage in corn decreased. The numbers of workstock and the receipts from sales of farm products declined sharply. Cash incomes were derived mostly from nonfarm sources.

The farm real estate situation, 1939-40, 1940-41, and 1941-42, M. M. REGAN and A. R. JOHNSON (*U. S. Dept. Agr. Cir. 662* (1942), pp. 45, figs. 8).—This is a continuation of the series previously noted (E. S. R., 83, p. 118). Substantial increases in land values and a strengthening of the farm real estate market characterized the farm real estate situation during the year 1941-42.

Experience after the last war clearly demonstrated the desirability of avoiding excessive increases in values during this war.

**Recent changes in tax rates on farm real estate in North Carolina, G. W. FORSTER** (*North Carolina Sta. Tech. Bul.* 72 (1942), pp. 28, figs. 7).—"The purpose of this study is to reveal the major causes of and the more important social and economic implications involved in changes in tax rates, and to suggest methods by which tax rates may be adjusted to the income of the taxpayer. These methods are designed to provide a uniform flow of revenue for the support of public institutions and services." The study covers the period from 1913 to 1940, with special attention to the periods 1920-40 and 1930-40. From 10 to 20 farms in each county representative of various types of farming, economic and social conditions, and physical factors were chosen for study, and data were secured from county records as to acreages, assessed value, property taxes levied, and tax rates. The State tax relief to property holders, changes in tax rates, causes for changes in rates, and the behavior of public expenditures are discussed. Tables and charts are included and discussed showing by years, 1920-40, the index of farm income by areas of the State, the movement of farm cash income and taxes per acre, average tax rates per acre, and index numbers in 8 South Atlantic States, farm real estate taxes per acre (1913, 1928, and 1940) in the 48 States, the relation of tax rates and farm income in typical counties of North Carolina, and the receipts and expenditures 1919-37 for schools in the State. Two methods—the budgetary method and the borrowing and repayment method—for the prevention of recurrence of past conditions as to taxes and expenditures are suggested, and the advantages of the methods and the difficulties in the way of their adoption are discussed.

**Farm taxation in Nevada, F. B. HEADLEY and M. L. CONNOR.** (Coop. U. S. D. A.). (*Farm Mangt. Bul. [Nev. Sta.]*, 3 (1942), No. 2, pp. [1]+14, figs. 7).—This is a brief discussion of land ownership, assessed valuations, owners' valuations, tax rates, etc. It is based on reports of State and county officers and the Nevada Taxpayers' Association and a study covering 51 farms in Churchill, Clark, Douglas, and Lyon Counties.

**Labor and power needs on crops in Bulloch County, Georgia, W. E. HENDRIX and W. T. FULLILOVE.** (Coop. U. S. D. A.). (*Georgia Sta. Cir.* 139 (1942), pp. 16, figs. 2).—The data were obtained in 1941 by the survey method from 172 farmers selected at random and are based on the usual production practices and normal crop yields in the county. Tables are included and discussed showing the usual number of man-, mule-, and tractor-hours used per acre of specified crops by production operations with different levels of equipment, and the usual amounts and distribution by half-month periods of the man-, mule-, and tractor-hours with one-mule and two-mule equipment and one-row and two-row tractors. The charts show the periods in which production operations are usually performed on different crops and the distribution by half-month periods of man-hours used on specified crops with two-mule equipment. The possibilities of fuller utilization of farm labor by increasing acreages and adding new crops are illustrated.

**A survey of newer haymaking methods on western Nevada farms, D. EVANS.** (Coop. U. S. D. A.). (*Farm Mangt. Bul. [Nev. Sta.]*, 3 (1942), No. 5, pp. [1]+9).—A field survey was made of farms in Douglas, Lyon, and Churchill Counties, using pick-up balers, pick-up choppers, or other labor-saving methods of haymaking. Tables show the tons handled per hour, man-hours per ton, and similar data for balers, choppers, loaders, buck rakes, etc. Because of the smallness of the sample, most of the data are for individual farms rather than averages.

**Dairy opportunity areas in New Hampshire**, H. C. WOODWORTH and J. C. HOLMES (*New Hampshire Sta. Bul.* 340 (1942), pp. 29, figs. 11).—"Data concerning the size and location of every dairy enterprise were obtained from town inventories and from the selectmen. Brief conferences on the productivity of fields and pastures, on the type of farms, the topography, the ease and difficulties of cultivation, the market outlets, and on the trend in dairying were held with individuals in each town." The land areas were differentiated as to dairy opportunities as favorable, marginal, unfavorable, and nonagricultural. Tables show for the State the distribution of farms and of cows by size of herds, distribution of herds and cows by dairy opportunity areas by counties, and the distribution of herds and cows by types of farms (commercial and noncommercial) and by dairy areas. A map shows the different dairy opportunity areas. Tables and a map for each county show the distribution of farms and cows by size of milking herds and dairy opportunity areas.

**Factors affecting dairy farm income**, M. L. CONNOR. (Coop. U. S. D. A.). (*Farm Mngt. Bul.* [Nev. Sta.], 3 (1942), No. 3, pp. [1]+5).—During a 6-yr. period 114 dairy farm records were obtained. These are scored on the basis of the following efficiency factors as above or below the average: Number of cows, price received for butterfat, butterfat per cow, return over feed cost per cow, return per \$100 worth of feed, number of animal units, and total productive work units. The different factors are discussed. The average net farm income increased from \$379 per year for the eight farms with none of the factors above the average to \$5,713 for four farms with all factors above the average.

**Economies of scale in the operation of country milk plants, with special reference to New England**, R. G. BRESSLER, JR. (Coop. 6 expt. stas., U. S. D. A., et al.). (*Boston: New England Res. Council Market. and Food Supply*, 1942, pp. 92, fig. 17).—This is a study of the relation of decreases in unit operating costs to increases in the scale of operation, under the most efficient operating conditions.

**Distribution of milk in Manhattan, Kansas, and methods of conserving tires**, R. W. HOECKER (*Kansas Sta., Agr. Econ Rpt.* 16 (1942), pp. [2]+14, fig. 1).—This report is based on data collected during the spring of 1942 from 17 of 20 milk distributors in the city and representing about 91 percent of the milk sold during the period. The retail and wholesale distribution are described and discussed. Possible alternate methods of distribution are also discussed.

"The greatest savings in tires and time could be obtained by the adoption of a unified wholesale delivery system. Substantial savings could be obtained, at considerably less inconvenience to the consumers, by the adoption of a unified alternate-day, house-to-house delivery system. Smaller but substantial savings can be made or already have been made by: Discontinuance of special deliveries; discontinuance of special trips to make collections; consolidation of routes, that is, discontinuing or exchanging customers that are at a distance from the main route; changing from early-morning to daylight delivery. The experience in Manhattan has demonstrated that if the public is sufficiently informed of the necessity of curtailing service, little opposition is offered."

**Livestock movement at Kentucky auction markets**, A. J. BROWN and C. D. PHILLIPS (*Kentucky Sta. Bul.* 432 (1942), pp. 32, figs. 8).—The volume of stock handled, total and per auction; size of auctions; receipts in different areas of the State; the proportion of receipts sold for slaughter; proportions of slaughter animals purchased by different types of buyers in different areas; the disposal of stocker, feeder, and breeding livestock in different areas; and the transportation of livestock to and from the auctions are described and discussed.

Forty-five livestock auctions were in operation in 1910. Total receipts at 43 auctions in 1939 were 1,802,609 head. Fifty-three percent of the cattle, 94 percent of the calves, 66 percent of the hogs, and 85 percent of the sheep and lambs were sold for slaughter. Order buyers and packer buyers purchased 65 percent of the cattle, 92 percent of the hogs, and 97 percent of the sheep and lambs sold for slaughter.

**Facilities and services of Pennsylvania freezer-locker plants, W. R. WHITACRE** (*Pennsylvania Sta. Bul.* 433 (1942), pp. [1]+13, figs. 3).—"The purpose of the study was to determine where locker plants were located and the services they offered patrons. It was also an aim of the study to learn who the locker patrons were, and how and to what extent they used the services offered by the plants. The importance of locker plants as a market outlet and the effect that the industry may have on the marketing of farm products were considered." The size and growth of the locker industry, the location, ownership, operation, facilities, services, rental rates, service charges, etc., are considered. The advantages and disadvantages of locker plants to the users and their use as market outlets for meats and vegetables are described.

The number of plants increased from 7 in 1938 to 40 in 1941. The operating plants reported 17,719 lockers, of which 81 percent were rented. The plants were generally in agricultural areas, and practically 74 percent of the patrons were farmers. Rental rates for lockers ranged from \$3 to \$17. Nine plant managers purchased 217,300 lb. of beef and 3,300 lb. of pork for resale. "Vegetables and fruits also were purchased by plant managers for urban patrons. Increasing numbers of farmers were freezing vegetables and fruits for sale."

**Seasonal prices of spring lambs on Kentucky auction markets, C. D. I'PHILLIPS and R. W. RUDD** (*Kentucky Sta. Bul.* 427 (1942), pp. 35, figs. 11).—Using data for five representative auction markets in central Kentucky for the years 1927-39, analysis is made of the seasonal patterns of prices and average weights; the percentage of lambs sold in different price groups; and the relations and effects of weights, drought, and income and general price level on the seasonal lamb prices.

The typical change in prices was a rise from the beginning of the marketing season (first week in April) to a peak in the seventh to ninth week, and then a decline during the remainder of the season, with some leveling off during the last 4 or 5 weeks. The average weight of lambs rose during the first 5 or 6 weeks of the season and then declined during the remainder of the season. In general, an increase in weight up to 80 lb. was accompanied by a rise in price per 100 lb. Above 80 lb., increase in weight was accompanied by a decline in the average selling price. The seasonal decline in average price was accelerated by the fact that as the season progressed the proportion of low-quality lambs increased.

**Crops and Markets, [October 1942]** (*U. S. Dept. Agr., Crops and Markets*, 19 (1942), No. 7, pp. 165-196).—The usual crop and market reports and tables on fertilizers, farm labor and wages, etc., are included.

**Foreign Agriculture, [November 1942]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 6 (1942), No. 11, pp. [2]+365-386, figs. 11).—The following articles are included: Agricultural Relations With Mexico, by K. Wylie (pp. 365-373); British County War Agricultural Committees, by M. E. Long (pp. 374-378); Poultry Improvement in Southeastern Europe, by C. E. Whipple (pp. 379-383); and Wartime Rationing in Eire (pp. 384-385).

## RURAL SOCIOLOGY

**Rural sociology and rural social organization, D. SANDERSON** (*New York: John Wiley & Sons; London: Chapman & Hall*, 1942, pp. XVII+806, figs. 127).—

This is a comprehensive study of rural society divided into four parts, dealing with the relation between rural sociology and rural social organization; environmental conditions; rural institutions, groups, and classes; and rural social organization in relation to the Great Society.

**Social problems [studied by the North Carolina Station] (*North Carolina Sta. Rpt. 1941, pp. 68-71, figs. 2*).—**It is shown that North Carolina leads nearby States in population growth. The population of 3,571,623 in 1940 was 12.7 percent greater than the 1930 population of the State. The number of Negro owners declined from 19,711 in 1930 to 18,245 in 1940, Negro sharecroppers from 34,805 in 1930 to 26,803 in 1940, and other Negro tenants from 22,334 to 15,191.

**Fifty years of population growth in Washington: A study of the trends in numbers, composition, vital traits, and migration of Washington population, P. H. LANDIS (*Washington Sta. Bul. 419 (1942), pp. 47, figs. 21*).—**The State of Washington, with a population of slightly more than 75,000 in 1880, increased in size to more than 1,736,000 in 1940. In 1940, the Washington population was 26 persons per square mile as compared with 44 per square mile for the Nation. In the decades of the thirties the urbanization rate slowed down, the urban population increasing by 37,430 and the rural by 135,365. Males predominated over females in numbers, although the sex ratio was approaching a balance. In age composition, the population is aging rapidly because of increasing longevity and a declining birth rate. From 1930 to 1940 the number of old people, 65 yr. of age and over, increased from 101,503 to 142,491, or from 6.5 percent of the total population to 8.2 percent, which represents an increase of 20.6 percent in one decade. By 1980, it is expected that the old people will constitute more than 15 percent of the total population, and number approximately 300,000. Considering the trend in age composition, the death rate should continue to rise, in which case, unless the birth rate also rises, it is only a matter of a short time until there would be no natural population increase in the State.

A striking characteristic of the Washington population is the large proportion living in cities of more than 100,000. Although the rural population has a considerably higher birth rate than the urban population, a considerable proportion of its children on reaching the economically productive and reproductive ages move to the cities, leaving the farm group deficient in the age group 20 to 44 yr. The women in the West Coast States have a more decided advantage over men in expectation of life than in the United States as a whole. The life expectancy of white women for 1930-39 was 66.1 yr., compared with the rate of 60.7 yr. for white males. It seems likely that the State will continue for some time to make a net gain from migration.

**Backgrounds of the war farm labor problem (*U. S. Dept. Agr., 1942, pp. [I]+IV+183, figs. 2*).—**The Bureau of Agricultural Economics and the Farm Security Administration have assembled the more important facts about the varied conditions of farm employment. Part 1 discusses the problems of farm labor and factors behind them, with recommendations for action. Part 2 is a description of the various classes of farm labor and the economic and social status of farm wage workers. Part 3 considers the farm labor market and legislative protection.

**Wanted—man power for Arizona farms, seasonal and year-round farm labor requirements, Arizona, 1935-42, E. D. TETREAU (*Arizona Sta. Bul. 186 (1942), pp. [2]+36, figs. 2*).—**The author shows that the problem of getting extra laborers for harvesting cotton and citrus fruits and tending truck crops in Arizona has become very serious. He indicates the amount of labor needed for Arizona farms as based on a study of conditions in Graham, Maricopa, Pima, Pinal, and Yuma Counties.

Rural youth in wartime Illinois, Randolph County, D. E. LINDSTROM, E. G. MOSBACHER, R. B. MCKENZIE, O. E. BAKER, N. T. FRAME, E. C. SECOR, ET AL.). (Coop. U. S. D. A. et al.). (*Illinois Sta., 1942, RSM-10, pp. [3]+9*).—This mimeographed publication presents facts gathered by the Rural Youth Group of Randolph County, Ill., in a survey of occupations, health, education, opportunities, and leisure time.

**Six months after commencement: An analysis of the occupational roles of 133,651 graduates from Washington high schools, classes of 1934 through 1941, P. H. LANDIS (*Washington Sta. Bul. 420 (1942), pp. 31, figs. 9*).—**Presented are the occupational roles of some 133,651 school youth 6 mo. after graduation, 65,940 boys and 67,711 girls graduating from high schools of the State of Washington in the classes of 1934 through 1941. This group accounts for between 60 and 70 percent of all youth of comparable age in the State of Washington during the period covered.

Among the conclusions drawn from the study are the following:

"The proportion of youth going on to college is decidedly affected by economic and employment conditions. The highest proportion go on to college during a time of normal business activity. At the depth of the depression the proportion was relatively low; with the war boom, the proportion going to college dropped precipitously, although in 1941 it had not fallen to the depression level of 1934. It is clear that a large number of young men and women in their teens are either willing to dispense with a college education or to defer it when the labor market is open to them. . . .

"The teen-age girls' largest gain in the labor market during the war period has been in the field of store and office work. They apparently have taken the places of older workers who have been drawn into the armed service or into other employment. The proportion of girls entering factory work and trades has about doubled, but the proportion in these fields remained small even for the class of 1941.

"The war-time labor market has opened for boys primarily in the field of factory work and trades. They have also found more openings in store and office work than previously, but the new openings in this field have gone primarily to girls. The proportion of boys entering agriculture is decidedly affected by the expansion of the urban labor market. A smaller proportion of the 1941 class than of any other class entered agriculture.

"The marked difference in college attendance of rural and urban youth suggests that urban youth value higher education to a greater extent, find it more essential to success in the urban environment, or that some other conditions in the social situation tend to push them on up the educational ladder. Either rural youth do not sense these values to the same degree, do not feel the same pressures, or for some other reason less often try to continue their education beyond the high school. It is possible that nearness of urban youth to institutions of higher learning or more adequate family income are factors.

"It is the country youth primarily who finds his way into agriculture after completion of the high school course. Despite the fact that the very small schools less often than the small city schools offer a Smith-Hughes course in agriculture, a higher proportion of their youth return to the farm. This may not in all cases be a deliberate choice on the part of the rural youth. It may be in part that the school has not given many farm youth an adequate understanding of other occupational possibilities. Certainly, it is due in part to the fact that agriculture is the **family** occupational heritage of a large proportion of youth in small school systems."

**The effect of status on attitudes in a New York rural community**, L. S. BEE ([*New York*] *Cornell Sta., Mimeog. Bul. 6* (1942), pp. [4]+51, pls. 5).—On the basis of studies of "a rather typical upstate New York village and the center of a dairy farming area," the author concludes that factors associated with persons' positions in the economic system are very significantly related to conservatism and liberalism. Conservatism is closely correlated with relative advantaged economic position in the community, education, and other factors.

[**Farmers' discussion group pamphlets**] (*U. S. Dept. Agr., Ext. Serv. and Agr. Adjust. Admin.*, 1935, D-1, pp. II+9, rev. 1936, pp. II+11; 1935, D-2, pp. II+6, rev. 1936, pp. II+6; 1937, D-3, pp. [2]+22, figs. 7; *Bur. Agr. Econ.*, 1942, D-4, pp. IV+57, figs. 7; *Bur. Agr. Econ. and Ext. Serv.*, 1942, [D-5], pp. 13).—This is a series of pamphlets "to assist organizations and individuals interested in establishing discussion groups, particularly in rural areas." The series deals with a brief guide to methods, how to organize and conduct county forums, the discussion leader's job, group discussion and its technics (a bibliographical review), and the organization of groups for discussion and action.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**An evaluation study of the introductory course in soils at Michigan State College**, L. M. TURK and P. L. DRESSER (*Mich. State Col. Ed. Res. Bul. 1* (1942), pp. [2]+56, figs. 2).—This publication presents a record of the development and evaluation of the introductory course in soils. The results suggest that a somewhat different organization of the course, involving giving some of the applied phases in advance of the basic and technical parts, would make for more interest in the technical aspects.

**Rural America today: Its schools and community life**, G. A. WORKS and S. O. LESSER (*Chicago: Univ. Chicago Press*, 1942, pp. XX+450, figs. [20]).—This is a description of rural education in the United States.

**Consumer education** (*Philadelphia: Frank Parker*, 1942, rev. ed., pp. [3]+75).—This loose-leaf processed working outline for a consumer education course for secondary schools is arranged for two semesters, the first being devoted to consumer goods and the second to consumer services. Following introductory chapters of a more general nature, the study topics on specific goods and services are presented in outline form, with accompanying references to teaching materials.

## FOODS—HUMAN NUTRITION

**Food and family living**, F. L. GORRELL, H. MCKAY, and F. ZUILL (*Chicago: J. B. Lippincott Co.*, [1942], pp. XI+522, [figs. 274]).—This textbook for high school students follows the same general scheme of presentation as used in *The Family's Food* (E. S. R., 79, p. 704) upon which the present edition is based, but with thorough revision, new illustrations, and attractive resetting. Throughout the several sections, dealing with (1) meal planning and preparation, (2) methods and standards of food preparation, (3) food management, and (4) relation of food to health, an effort is made to present food and nutrition problems in relation to daily living, both at home and in the workaday world.

**A microscopic study of bread and dough**, M. E. BURHANS and J. CLAPP (*Cereal Chem.*, 19 (1942), No. 2, pp. 196-216, figs. 36).—This paper reviews briefly some of the previous work in the field, discusses the problem of making suitable sections, and notes the main points of the adopted microscopic procedure. Thirty-six photomicrographs are presented in the series, beginning with the ingredients and following with the progression of dough samples taken after each operation

and terminating with the baked bread. The descriptions given are based on the three magnifications used routinely and concern the starch, yeast, gluten, fatty substances, and the gas cells produced by leavening. The causes and effects of the structural changes observed in the material during the manufacturing are discussed under six headings, which are summarized as follows:

"(1) Mixing results in an entirely homogeneous suspension of starch, yeast, and fats in a glutinous matrix. Flour particles lose their autonomy. (2) Processing improves the bread by grouping the starch and more efficiently sealing the gas pockets by gluten segregation. Molding and proofing are fundamental operations. (3) Baking changes, involving oven spring, starch gelatinization, coalescence of the lipides, and leavening are visually demonstrated in the photomicrographs. (4) Shortening distribution in bread dough is indicated by the technic used. The observations suggest a concentration of the shortening upon the starch-gluten interfaces, effected principally by mixing, and coalescing during baking into sizable collections of specifically stained material. (5) Leavening involves a preliminary diffusion away from the point of  $\text{CO}_2$  formation. The heat of baking affects gas solubility, vaporization, enzymatic behavior, and gluten properties. (6) The crumb qualities (grain, texture, and to some extent color) are directly correlated with microscopic structures, particularly the small intramural gas cells."

**Nutritive value of leafy vegetables**, O. SHEETS, O. A. LEONARD, and L. McWHIRTER (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 11, pp. 1, 2).—Seven-Top turnip greens grown on a uniformly fertilized plat were harvested at from 7- to 10-day intervals, beginning about  $1\frac{1}{2}$  mo. after planting, and analyzed for moisture, iron, carotene, and ascorbic acid. The data presented show that there was much variation in these constituents, apparently associated with growth and probably with weather conditions related to season. Thus, the early harvests were richer in iron and usually richer in carotene, in percentage of the dry sample, than the more mature leaves harvested at later dates. A decrease in ascorbic acid in the leaves appeared to be associated with freezing weather occurring in mid-December.

**Factors influencing the nutritive value of the tomato: A review of the literature**, K. C. HAMNER and L. A. MAYNARD (*U. S. Dept. Agr., Misc. Pub.* 502 (1942), pp. 23).—This publication reviews and summarizes published experimental work that has provided information regarding factors related to variations in total solids, acidity, pigments, mineral content, ascorbic acid, carotene, and other vitamins in tomatoes. The factors involved include location, season, temperature, light, water supply, variety, stage of development and maturity, and nutrition of the plant. Variations in ascorbic acid content of tomatoes during the canning process and the production of juices and other products are also considered. The bibliography totals 142 references.

**Dietary uses of the banana in health and disease**, L. J. BOGERT (*New York: United Fruit Co., [1942], rev. and enl., pp. 67, pl. 1, figs. 3*).—This booklet presents a brief review of the scientific literature covering the nutritive value of the banana and the clinical evidence of its dietary uses, the latter being interpreted in the light of modern nutrition. The present review (*E. S. R.*, 85, p. 412) has been amplified to cover the important papers which have appeared between 1939 and 1942.

**Dehydrated baked beans**, W. B. ESSELEN, JR., and S. G. DAVIS. (*Mass. Expt. Sta.*). (*Canner*, 95 (1942), No. 20, pp. 18, 20, figs. 2).—The beans are baked with a well-seasoned brine formula, since some of the flavor is lost during the drying, and are dried, after discarding the salt pork, in a forced circulation, hot-air tunnel dehydrator at a temperature of about  $140^\circ\text{F}$ . With a load of  $1\frac{1}{4}$

lb. of baked beans per square foot of tray, the product is dried to a 3- to 4-percent moisture content in from 8 to 10 hr. The dehydrated beans are packaged in a moisture-vaporproof package. For rehydration they are soaked for about 1½ hr. in water added in the proportion of about 2 parts by weight to 1 of beans. The heated, rehydrated beans are characteristic of the original baked beans except that they are somewhat less attractive because of their tendency to split open during the dehydration.

**Dehydration of sauerkraut**, W. V. CRUESS, E. BALOG, and P. VAN HOLTEN. (Univ. Calif.). (*Canner*, 95 (1942), No. 24, pp. 13-14).—Blanching of sauerkraut, preferably steam blanching, before dehydration gave a product showing greater regain upon soaking and greater cooked weight than did the dehydrated unblanched sample, but it was gray and inferior in color. When the boiled sauerkraut juice was added to the steam-blanching sauerkraut dried to the "tough dry" but not the "brittle dry" stage, the partially dried sauerkraut readily soaked up the juice, and the dehydration could then be completed. This drying in juice increased the yield and nutritive value of the dehydrated sauerkraut and gave a product superior in flavor to that dried without juice. It was essential that the juice be boiled in order to destroy enzyme action, otherwise a dehydrated product of inferior flavor resulted. Other tests showed that exposure of the steam-blanching sauerkraut to SO<sub>2</sub> fumes for 20 min. before drying gave a final product of lighter color than the one not sulfured. Reduction in volume of the dehydrated product was accomplished by compressing the sauerkraut before completely dry and while still tough. The resulting "boards" about ½ in. thick could then be dehydrated to bone dryness (moisture less than 5 percent). Fresh sauerkraut containing 1.4 percent total acid as lactic gave dehydrated products, which, after soaking and cooking, contained (1) untreated, 0.48 percent; (2) dried with juice, 0.60; and (3) SO<sub>2</sub> treated, 0.50 percent total acid. Presumably acetic acid volatilized during drying.

**Nutritional studies on powdered wool**, J. I. ROUTH (*Jour. Nutr.*, 23 (1942), No. 2, pp. 125-130, figs. 3).—Wool, powdered by grinding in a ball mill, was incorporated at 15- and 20-percent levels as the sole source of protein in an otherwise adequate diet. In ad libitum feeding tests with young rats the powdered wool failed to support growth, whereas other rats of the same strain gained from 3 to 4 gm. per day when 15 percent casein replaced the wool. Tryptophan, methionine, histidine, and lysine were found to be present in suboptimal concentration in the powdered wool. Supplementation of the wool diet with these amino acids resulted in moderate growth.

**Sugar substitutes and their uses**, J. E. RICHARDSON (*Montana Sta. Cir.* 168 (1942), pp. [4]).—Suggestions are given for using honey, corn sirup, sorghum, or medium dark molasses in place of sugar in cake making. Some tested recipes are given showing the original proportions and the substitutions.

**Foods and drugs**, E. R. TOBEY (*Maine Sta. Off. Insp.* 183 (1942), pp. 153-280).—This annual report (E. S. R., 86, p. 700), giving the results of analyses of official samples of foods and drugs, is concerned chiefly with dairy products (milk, cream, and ice cream), packing oils for sardines, and shellfish (clams).

**Co-operative research in nutrition**, P. M. NELSON. (Iowa Expt. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 8, pt. 1, pp. 528-530).—This is a brief report of the organization, scope, and significant findings to date of the north central cooperative project on the nutritional status of college women, reports of various phases of which have been noted from original sources.

**Food production and nutrition**, N. W. PIRIE (*Nature [London]*, 149 (1942), No. 3777 pp. 318-319).—This is a brief summary of papers presented and the ensuing discussion at a meeting of the British Nutrition Society devoted to the

topic **Food Production and Distribution in Relation to Nutritional Needs**. The formal papers presented were *The Agricultural Implications of a Food Policy Based on Nutritional Needs*, by J. Orr; *Rival Claims of Animals and Man for Food*, by N. C. Wright; *Animals as Food Converters*, by E. T. Halnan; and *Planning for Agricultural Production*, by J. Russell.

**A scientific food policy** (*Nature* [London], 149 (1942), No. 3777, pp. 309-311).—An editorial discussion of some of the problems involved in post-war food production planning as discussed in the symposium noted above.

**What vegetable crops best meet the demands of a food emergency?** J. H. MacGILLIVRAY, G. C. HANNA, and P. A. MINGES. (Univ. Calif.). (*Canner*, 95 (1942), No. 19, pp. 16-18).—It is pointed out that from the standpoint of agricultural wartime economy vegetables should be selected not merely for their nutritive value but with consideration for the amounts of food constituents produced per acre per man-hour. Other items, including palatability and consumer preference, are less important. In the present study the efficiency of 26 major crops is evaluated from existing information on composition, man-hour requirements, and average yields, the amounts of each food constituent per acre and per acre man-hour being determined for each crop. Yield ratings are determined by arranging the crops in descending order with respect to their yields of eight selected constituents (protein, calcium, iron, calories, vitamin A, thiamin, riboflavin, and ascorbic acid), and an index value of 1 is assigned to the vegetable rating highest in each group. The index values as determined for each vegetable with respect to the eight food constituents are added to give the final efficiency rating of the vegetable. The same procedure is followed in obtaining the rating for the amount of food produced per acre man-hour. Thus rated, spinach, winter squash, potatoes, and cabbage ranked as the best vegetables if the ratings for yield per acre and per acre man-hour were combined. The growing period, and hence the length of time the crop occupies the land, and the number of man-hours and length of time required to grow the seed are further considerations in evaluating the economy of a nutritionally important crop. It is concluded from the data presented that certain vegetable crops should possibly be eliminated from production if extreme economy of labor and equipment becomes necessary in the wartime food production program.

**Nutrition survey of population groups: Report of a conference on methods and procedures** (*Pub. Health Rpts.* [U. S.], 57 (1942), No. 6, pp. 189-194).—In this report of a conference held under the auspices of the Rockefeller Foundation and participated in by nine physicians with experience in this field, the results of the discussion have been condensed in the form of opinions and recommendations under the general headings dietary studies, clinical examination, and special tests in the assessment of the nutrition of populations. In summary the statement is made "that an assessment of the nutritional status of a population can be done at present by conducting, on a suitable sample, a properly planned dietary and food intake survey, together with an adequate physical and medical examination, the latter to include a slit-lamp examination of the eyes and the securing of blood samples for the determination of hemoglobin, plasma ascorbic acid concentration, and the concentration of blood serum or plasma albumin. While it is recognized that appraisal on this basis will give only partial information, more complete studies must await the development of additional methods."

**Medical evaluation of nutritional status, VII, VIII** (*Milbank Mem. Fund Quart.*, 20 (1942), No. 1, pp. 6182, fig. 1; pp. 83-96).—These two papers continue the series (E. S. R., 87, p. 741).

**VII. Diets of high school students of low-income families in New York City, D. G. Wiehl.**—Approximations of the diets of the individual high school students in the low-income group whose nutritional status has been noted in earlier papers of the series were calculated from the diet histories obtained by the interview method, both from the students at the clinic operated for the investigation and from home visits, and were compared with requirements for the principal food constituents as based on the National Research Council's daily allowances except for calories, for which calculations were made from age and estimated activity of the individual subjects. The percentages of the subjects of each sex and each age group with calculated diets furnishing less than the allowances recommended and also the percentages with diets furnishing less than two-thirds the recommended allowances are presented in graphs and tables.

In the first category 78 percent of the boys and 70 percent of the girls were classified as deficient in calories and 27 percent of the boys from 13 to 15 yr. of age and 52 percent of the girls from 16 to 19 yr. deficient in protein. For all of the other constituents more than 60 percent of the subjects in one or more of the sex-age groups had less than the recommended allowances. In the second category approximately 20 percent of all the subjects had diets furnishing less than two-thirds of the estimated requirements of calories; from 30 to 42 percent received less than two-thirds of the standard requirements for vitamin A; from 25 to 34 percent received less than two-thirds of the ascorbic acid requirement; and from 20 to 31 percent less than two-thirds of the calcium requirement. For iron, 26 percent of the younger and 32 percent of the older girls and 7 percent of the boys were in this group; for riboflavin 42 percent of the older boys and from 16 to 18 percent of the younger boys and all of the girls; and for thiamin 23 percent of the older boys and only 10 percent of the younger boys and the girls. The item showing the greatest deficiency was vitamin A; calcium and ascorbic acid ranked next in degree of deficiency; and the least deficiency was in protein.

Attention is called to observations reported in earlier papers of the series of the prevalence of avitaminosis A, ariboflavinosis, and low hemoglobin values in about one-fourth of the total group and low plasma ascorbic acid levels for the total. The high prevalence among the girls of diets considered to be deficient in iron was not confirmed by their hemoglobin levels, leading to the suggestion that an allowance of 15 mg. of iron daily may be questionable.

**VIII. The school lunch as a method for improving diets of high school students, E. K. Stamm and D. G. Wiehl.**—In connection with the dietary analyses noted above, a special analysis was made of the food values of lunches eaten at school either as free, bought, or brought from home. As these showed that for the most part the lunches contributed a smaller proportion of the nutrients in which most of the children were deficient than of others less frequently deficient, practical suggestions are given for increasing the nutritive value of the school lunches in constituents most likely to be deficient.

**Nutritional requirements of children: A résumé, W. J. DANN and W. C. DAVISON** (*Amer. Jour. Diseases Children*, 63 (1942), No. 2, pp. 366-370).—This résumé presents the daily allowances of the various dietary essentials for children, from under 1 yr. of age to 13-15 yr., as recommended by the committee on food and nutrition of the National Research Council (May 1941) and the committee on vitamins of the American Academy of Pediatrics. The discussion indicates briefly how these allowances may be met in dietary practice.

**Army food and fighting efficiency, P. P. LOGAN** (*Food Indus.*, 14 (1942), No. 5, pp. 33-36, figs. 3).—This address describes the work of the Subsistence Branch of the Quartermaster Corps of the U. S. Army in subsistence procure-

ment, research, and development. Types C, D, and K rations for reserve, emergency, and parachute use are described.

**Food habits of South Carolina farm families, A. M. MOSER** (*South Carolina Sta. Bul. 343* (1942), pp. 38, figs. 12).—In this publication records of the food consumption of white and Negro farm families in the State are summarized and presented in semipopular form as the basis for recommending improvements in dietary planning. The material summarized includes the reports of studies made in the Piedmont (E. S. R., 73, p. 557) and the Lower Coastal Plains (E. S. R., 81, p. 866) areas and 401 weekly records from the consumer purchase study of the U. S. D. A. Bureau of Home Economics taken in the tobacco-cotton growing areas of the Upper and Lower Coastal Plains. In all, 669 records of white and 404 of Negro families fairly well distributed in different sections of the State were used.

The dietary patterns of white farm families in the Piedmont and Lower Coastal Plains sections are presented in graphs and tables in terms of average yearly consumption per person of milk, eggs, vegetables and fruits, lean meats, poultry and fish, grain products, fats, and sugars in low-cost and moderate-cost dietaries. The nutritive value of the diets is discussed in terms of standard allowances of the Board of Food and Nutrition of the National Research Council. Attention is called to seasonal variations and to home production of foods in these areas. Since the records of the tobacco-cotton farms section did not cover all seasons, it was not possible to give a picture of the year's supply, but the average per capita quantities calculated for the low-cost and moderate-cost fall dietaries of white farm families are compared with those of the same season for the other two sections. From the records of Negro families, estimates are reported of the average per capita consumption of the different classes of foods for 26 weeks in the fall, as indicated by 49 weekly food records from the Piedmont, 91 from the Lower Coastal Plains, and 107 from the tobacco-cotton area.

The data for the various groups are further discussed as to frequency of good, fair, and poor dietaries of owner operators, tenant operators, and sharecroppers (or wage workers) among the white and Negro families, and finally from the average good dietaries of the Piedmont and Lower Coastal Plains groups, two types of farm family food plans are suggested and discussed—one suitable when plenty of milk is available and the other with less milk and more lean meat. This section of the report contains practical advice with respect to planning the food supply of individual families based on the dietary patterns proposed, with certain recommendations which, it is emphasized, should be followed to provide the necessary food values economically throughout the year.

**Hematologic values for normal healthy men 16 to 25 years of age, C. J. HAMRE and M. H. AU.** (Hawaii Expt. Sta.). (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 10, pp. 1231-1244, fig. 1).—The results of studies of normal values for the various blood elements for men are assembled from the literature and presented for comparison with the data obtained in determinations, by methods noted, of the blood values of 137 healthy young men residing in the Hawaiian Islands and ranging in age from 16 to 25 yr. These men were of several different races, the larger number being Caucasian, Chinese, and Japanese. Statistical evaluation of the data obtained indicated that age or race differences did not occur in any of the blood elements. Since the blood values obtained agreed closely with those in the summary of investigations in other parts of the world, it is concluded that blood values for men in the Hawaiian Islands do not differ significantly from those of men residing elsewhere. Fifty-nine references are given.

**The role of diet in blood regeneration**, A. BIESTER and J. M. LEICHSENBERG (*Minnesota Sta. Tech. Bul.* 153 (1942) pp. [1]+34, figs. 6).—The authors, with the collaboration of L. M. Burrill, L. M. Norris, and H. H. Deinard, in this bulletin present the results of an investigation dealing with the effects of certain nutrients and foods on the recovery of dogs from hemorrhagic anemia. The basal ration employed was that used in a previous study of the blood picture in hemorrhagic anemia in dogs (*E. S. R.*, 83, p. 140), and the criteria for assessing progress included hemoglobin and red cell volume regeneration, red cell count, and red cell size as measured by mean diameter and mean corpuscular volume.

"Hemoglobin production and red cell volume regeneration were most satisfactory when autoclaved yeast was introduced into the ration immediately following a control period on the synthetic food, and were least satisfactory when autoclaved yeast or wheat was included in the diet. When some essential material from autoclaved liver was supplied, apparently reserves built up during the control period became available. Confirming earlier studies on hemorrhagic anemia which has not been satisfactorily treated, red cell counts exceeded normal values and did not return to the desired level until cells of normal size were produced. Mean cell diameter and mean corpuscular volume values indicated a marked microcytosis at the beginning of each experimental period. Red cell diameter and mean corpuscular volume varied in opposite directions in many of the tests. Diameter showed the greatest increase when the diet included raw liver or liver which had not been heated above 100° C., and the greatest decrease in two series of experiments in which autoclaved liver was fed. The most striking increase in mean corpuscular volume occurred when thiamin was added to the autoclaved liver diet. Apparently the restoration of total red cell volume and hemoglobin is governed by a different set of factors from those which operate in return of red cell diameter or individual cell volume to prehemorrhagic levels."

**The effect of operator on the variability of basal metabolism data**, D. CEDERQUIST. (*Kans. Expt. Sta. and State Col.*). (*Jour. Lab. and Clin. Med.*, 27 (1942) No. 10, pp. 1328-1329).—A statistical study by analysis of variance of data obtained in 450 basal metabolism tests conducted by five operators on 225 women between 15 and 45 yr. of age under presumably standard conditions showed that intraday variation was not the same for all technicians. The difference between the mean squares of the records of one technician on the same day was about 2½ times that of one of the other technicians, a difference of statistical significance. No definite explanation for the differences noted between technicians is offered, but the possibility is suggested that they may have been due to differences in the sensitivity of the operator to the interpretation of standard conditions.

**Adequacy of simplified diets for guinea pigs and rabbits**, A. G. HOGAN and J. W. HAMILTON. (*Mo. Expt. Sta.*). (*Jour. Nutr.*, 23 (1942), No. 6, pp. 533-543, figs. 2).—In continuation of earlier attempts to determine the nutritional requirements of rabbits (with a few preliminary trials with guinea pigs) by the use of simplified diets (*E. S. R.*, 72, p. 522), success has been achieved with respect to growth at a normal rate of both species on simplified diets in which from 5 to 15 percent of dried yeast or 10 percent of a water extract of dried liver was used as the source of all water-soluble vitamins. For successful reproduction and raising of the young additional vitamin K and vitamin E were required, but both species had normal growth without added vitamin K. When all of the water-soluble vitamins were supplied as the pure compounds now available, the rate of growth was subnormal and mortality was high.

**The relation of the pH of intestinal contents to calcium and phosphorus utilization, J. H. JONES** (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 557-567).—To determine whether the previously observed favorable influence of fat on calcium and phosphorus utilization (E. S. R., 86, p. 558) was due to the action of the fat in increasing the acidity of the intestinal tract, a study was made of the effect of a number of substances on the pH of the intestinal contents of rats and simultaneously on the calcification of bone. pH determinations made with a glass electrode pH meter on the pooled contents from corresponding intestinal sections of several animals showed that the distal one-fourth of the small intestines was the most alkaline portion of the intestinal tract. Lard, oleic acid, and vitamin D added to the rachitogenic diet increased the acidity in the lower ileum and less consistently in the cecum and colon. These substances showed definite antirachitic action, which was most pronounced in the case of vitamin D although it did not produce a lower intestinal pH than did lard or oleic acid. The addition of aluminum sulfate to a stock diet resulted in severe rickets and an increase in pH in most of the intestinal tract. The addition of dibasic phosphate protected the animals against rickets without changing the pH of the intestinal tract. Ammonium chloride, calcium chloride, and triacetin were without effect on the pH of intestinal contents or on calcification. Lactose produced as much acidity in the lower intestinal tract as did lard but did not show any antirachitic action. Oleic acid and sodium oleate effected similar pH reactions in the upper small intestines, but the acid produced the greater acidity in the lower ileum and exhibited a definite antirachitic action, whereas the soap did not. It is considered that these data do not definitely eliminate an increase in acidity as the method by which fats beneficially influence calcification, but that they do throw considerable doubt on this theory.

**The interrelationship of calcium, phosphorus, and nitrogen in the metabolism of pre-school children, J. E. HAWKS, M. M. BRAY, M. O. WILDE, and M. DYE.** (Mich. Expt. Sta.). (*Jour. Nutr.*, 24 (1942), No. 3, pp. 283-294).—Previous studies (E. S. R., 84, p. 271) dealt with the effect of increasing the protein content of the diet on the protein and caloric utilization of five preschool children receiving, during 15- to 24-day periods, diets containing, first, 3 and then 4 gm. protein per kilogram of body weight. For two children, whole egg, meat, and milk were used to increase the N content of the diet, while for the others egg white and gelatin were used. Data, obtained in these studies, on the Ca, P, and N balances of the children are here presented, and the interrelationships are summarized as follows:

"The higher protein diet had no effect on calcium absorption or retention. It caused a decrease in the absorption of phosphorus, but there was a better utilization of the amount available. There was an increase in both nitrogen absorption and retention. Weight gains were greater on the 4- than on the 3-gm. protein diet and represented different types of tissue growth. Decided increases in nitrogen retentions and significant changes in retention ratios for Ca : P, N : Ca, N : total P, and N : nonosseous P suggested that muscle and other soft tissue accounted for the greater proportion of the increased weight gains. There may have been additional bone growth in three children who had increased calcium retentions."

The authors were assisted by V. H. Wiltgen and A. Kirkpatrick.

**Vitamin content of honeys, M. H. HAYDAK, L. S. PALMER, M. C. TANQUARY, and A. E. VIVINO.** (Minn. Expt. Sta.). (*Jour. Nutr.*, 23 (1942) No. 6, pp. 581-588).—Thiamin, determined by the method of Hennessy and Cerecedo (E. S. R., 82, p. 588), averaged  $5.5 \pm 0.250$   $\mu\text{g}$ . per 100 gm. in 29 samples of honeys from different localities in Minnesota; 31 honeys from different regions of the United States and representing various nectar sources varied from 2.1 to 9.1  $\mu\text{g}$ . per

100 gm.; and 7 honey samples from foreign regions varied from 2.2 to 9.1  $\mu$ g. per 100 gm. of thiamin. Values obtained for other vitamins per 100 gm. of these same samples, respectively, were as follows: Riboflavin, determined by the method of Snell and Strong (E. S. R., 82, p. 587),  $61.0 \pm 2.474$ , from 35 to 137, and from 47 to 145  $\mu$ g.; pyridoxin, determined by the Scudi method (E. S. R., 87, p. 11),  $299.0 \pm 11.457$ , from 210 to 480, and from 240 to 460  $\mu$ g.; pantothenic acid, by the method of Strong, Feeney, and Earle (E. S. R., 86, p. 588),  $105.0 \pm 5.54$ , from 25 to 192, and from 50 to 150  $\mu$ g.; nicotinic acid, by the method of Melnick and Field (E. S. R., 86, p. 11),  $36.0 \pm 3.486$ , from 4 to 92, and from 4 to 94 mg.; and ascorbic acid, by the Bessey method (E. S. R., 82, p. 14),  $2.4 \pm 0.155$ , from 0.5 to 6.5, and from 1.3 to 2.8 mg. It is pointed out that the variable amount of the vitamins found in the different samples probably depends on the source of the honey and the number of pollen grains in the product. Clarification of honey with diatomaceous earth resulted in marked reduction in the vitamin contents, amounting to from one-third to almost one-half the original values.

**Studies on the influence of vitamin A and vitamin C on certain immunological reactions in man**, A. E. FELLER, L. B. ROBERTS, E. P. RALLI, and T. FRANCIS, JR. (*Jour. Clin. Invest.*, 21 (1942), No. 2, pp. 121-137, figs. 7).—In this very extensive investigation five human subjects were given a diet adequate in all factors except for the specific vitamin being studied, and during the period of observation, which extended for 14, 26, 20, 6, and 19 weeks, respectively, weekly or biweekly determinations were made of the content of vitamin A, carotene, and ascorbic acid in the plasma and in certain instances in the white blood cell platelet layer. At similar intervals for the individual subject observations were made on five immunological reactions selected because of their diversity and because each represented an antibacterial or antiviral phenomenon.

"The results of the various immunological tests were not significantly influenced by the following conditions: (1) Marked and prolonged changes in the plasma levels of vitamin A or vitamin C or abrupt rises in the concentration of vitamin A in the plasma (two patients); (2) severe deficiency in vitamin C followed by a period during which the subjects were flooded with the vitamin (two patients); (3) a period of 17 consecutive weeks on a regime deficient in vitamin A, followed by a period of 2 weeks during which the subject received large doses of the vitamin daily. Certain variations in the results of the immunological tests occurred, but these alterations were either no more marked than those occurring in normal persons or were adequately explained on some basis other than a deficiency or sufficiency of vitamin A or vitamin C."

**The utilization of carotene and vitamin A in the rat**, R. TREICHLER, A. R. KEMMERER, and G. S. FRAPS. (Tex. Expt. Sta.). (*Jour. Nutr.*, 24 (1942), No. 1, pp. 57-64).—In this attempt to throw further light on the relative availability of vitamin A and carotene, three series of experiments on weanling male rats were run. The first consisted of a comparison of the vitamin A storage in the livers of rats receiving for 14 days from weaning equivalent amounts (10 International Units daily) of vitamin A potency as found in cod-liver oil, carotene dissolved in cottonseed oil, and carotene as contained in alfalfa leaf meal. In the second the effect was determined of the length of the depletion period (2 weeks and 4 weeks) on the vitamin A storage in the liver. In the third a comparison was made of the storage of vitamin A in the liver during 7 days on the basal diet of the other two series and the same with yeast replaced by an equal weight of cornstarch. The paired feeding technic was used throughout, vitamin A was determined by the spectrographic method of Fraps and Kemmerer (E. S. R., 79, p. 100), and the data were treated statistically by the analysis of variance.

Increased retention of vitamin A was found in all diet groups over the values of the controls at the beginning. The increase was greatest in the animals receiving their vitamin A in cod-liver oil, next in those receiving carotene in cottonseed oil, and least in those on alfalfa meal. On the basis of 100 percent efficiency for cod-liver oil, the efficiencies of the other sources were 59 and 21 percent, respectively, with carotene in alfalfa meal only 35 percent as effective as carotene dissolved in cottonseed oil. All differences were significant, as was the increase in the vitamin A storage in the negative controls. This was traced in the third series to the presence in yeast of a substance capable of giving a false or pseudo vitamin A value. The necessity in such experiments of using the paired feeding technic is emphasized.

**Vitamin A and dark-adaptation: Effect of alcohol, benzedrine, and vitamin C.** S. YUDKIN (*Lancet* [London], 1941, II, No. 26, pp. 787-791, figs. 6).—Normal variations in dark adaptation and in vitamin A content of the blood were found to be as follows:

Final rod thresholds for any subject varied by about 0.2 log unit from day to day, or about 0.1 log unit in a few hours and hardly at all in 1 hr.; the cone threshold varied by about 0.3 log unit from day to day and about 0.2 log unit over shorter periods; the rod-cone transition time varied up to about 2 min. from day to day but less than 1 min. in 1 day; the resting level of vitamin A in the blood varied by about  $\pm 5$  percent over periods of days or weeks and was not affected by food; and variations in dark adaptation and blood vitamin A were found to be quite independent and might be in opposite directions.

To determine whether or not a case of clinical night blindness is due to vitamin A deficiency, the author recommends that, following a preliminary dark-adaptation test, large doses (about 100,000 International Units of vitamin A) be given daily for 10 days, and a dark-adaptation test 24 hr. after the last dose. An improvement in dark adaptation lasting more than 24 hr. after the tenth dose indicates that the night blindness is due to deficiency of vitamin A. If no improvement occurs, another dose is given and dark-adaptation tests are made at intervals during the following 24 hr. If no transient response occurs, it can be assumed that the night blindness is not due to lack of vitamin A. No relation was found between the degree of night blindness and the dose required to produce a definite cure. In single subjects dark-adaptation tests and blood vitamin A determinations during dosing with vitamin A led to the conclusion that in any subject there is a critical level of blood vitamin A below which there is a subnormal rod threshold, but that the threshold is not affected by a blood vitamin A higher than the critical level. Both alcohol and benzedrine produced transient improvement in dark adaptation with no corresponding rise in vitamin A. Ascorbic acid was without effect even in subjects shown to be deficient in this vitamin.

**The relation between dark adaptation and the level of vitamin A in the blood.** C. HAIG and A. J. PATEK, JR. (*Jour. Clin. Invest.*, 21 (1942), No. 4, pp. 377-383, figs. 2).—Data are reported and discussed on (1) 60 individual dark adaptation tests (Hecht apparatus) made on 37 normal persons between the ages of 20 and 45 yr., (2) the plasma vitamin A and total carotenoid levels in 44 normal persons, and (3) 67 simultaneous dark adaptation and plasma vitamin A and carotenoid measurements on 14 normal persons, 18 patients with cirrhosis of the liver, and 7 with various other chronic diseases.

In (1) no sex differential was found in dark adaptation, but in (2) the mean vitamin A plasma levels for the women were found to be 14 percent lower than for the men and the mean carotenoid levels the same. In (3) when the cirrhotic and normal groups were considered separately, no significant correlations were found between either the plasma vitamin A or carotenoid levels and the dark

adaptation values, but when all of the subjects were grouped together some degree of correlation was evident. In discussing these findings with reference to earlier work of the authors and others, it is suggested that when various complicating factors are excluded, dark adaptation values may be considered a measure of the utilization of vitamin A by the retina, while vitamin A in the blood is an index of the amount stored in the liver.

**The effect of the level of fat in the diet upon utilization of vitamin A,** K. D. MUELDER and E. KELLY. (Mich. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 4, pp. 335-344).—In this second phase of an investigation of the effect of single factors on the utilization of vitamin A by the rat (E. S. R., 85, p. 700), it was found that the inclusion of fat at a level of 10 percent of the basal diet resulted in significant gains in weight over those on the basal diet alone but not over those on the diet containing 5 percent fat. For the levels of fat and vitamin A used, the level of vitamin A proved to be a more important factor than that of dietary fat in producing highly significant gains in weight. Growth in length was not affected by changes in the fat level, but was significantly increased by increased vitamin A. Fat had no significant effect at the levels fed, and vitamin A at all levels decreased the incidence of abscesses.

**Studies of the B vitamins in the human subject, I-V** (*Amer. Jour. Med. Sci.*, 202 (1941), No. 4, pp. 502-512, figs. 7; 512-516, figs. 2; 203 (1942), Nos. 1, pp. 114-120; 3, pp. 388-397, fig. 1; 4, pp. 569-577, fig. 1).

I. *The intake of thiamine and its relation to other dietary constituents in food selected by the normal subject*, K. O. Elsom and T. E. Machella.—In a selected group of seven essentially normal women who were allowed to select freely from an adequate diet for a period of from 15 to 39 days, during which all of the food eaten was weighed for diet calculations of thiamin content (with occasional analyses), the thiamin requirements of the individual subjects were calculated according to the Cowgill formula for comparisons with actual intake, and 24-hr. urines were analyzed for thiamin excretion. For the group as a whole the average daily intake exceeded the theoretical requirement by 40 percent, but the individual intakes ranged from 6 to 115 percent above the requirement. There was a wide variation in intake, not only among the different subjects but also from day to day in the same individual, the variations in both cases being due to the food habits of the individual. A linear relationship was found to exist between the daily intakes of protein and of thiamin, a positive correlation but of lesser degree between fat and thiamin intake, but no correlation between carbohydrate or calorie intake and thiamin.

II. *Urinary excretion of ingested thiamine in patients with chronic hepatic disease*, T. E. Machella and K. O. Elsom.—Six women, three of whom were normal and the others had clinical and laboratory evidence of chronic hepatic disease, were maintained for from 16 to 37 days (after a preliminary observation period of 2 weeks) on a diet calculated to meet the individual thiamin requirements and were then given supplementary doses of thiamin up to as much as 1,000  $\mu$ g. daily. The 24-hour excretions of thiamin were determined throughout. On the unsupplemented diet there was no essential difference between the patients with hepatic disease and the controls in the percentage of ingested thiamin excreted in the urine, but on the supplemented diet the excretion was much less in the patients than in the controls. Three possibilities are suggested for the lessened excretion of thiamin—disturbed renal function, previous state of tissue unsaturation, and impaired absorption from the intestinal tract. Impaired absorption is considered the most likely cause. The authors had the technical assistance of C. S. Chornock.

**III. The response of cheilosis to vitamin therapy, T. E. Machella.**—Among 17 cases of cheilosis treated in different ways, the lesions of 8 of 13 treated with pyridoxin subsided within from 3 to 14 days and of another in 26 days. The 4 not responding to pyridoxin also failed to respond to riboflavin, which, in addition, proved ineffective in the 4 other cases. In 3 with clinical and laboratory evidence of scurvy, improvement in the lip lesions was shown only when the scorbutic state had been corrected by vitamin C. The observations are thought to indicate that cheilosis is not necessarily a manifestation of riboflavin deficiency alone.

**IV. Mental changes in experimental deficiency, H. E. O'Shea and K. O. Elsom.**—In this study in which the authors had the technical assistance of R. V. Higbe, eight women, four of whom were on an adequate diet and the others on the basal diet of the earlier studies supplemented with one-half of the theoretical requirement of the B vitamins, were subjected to various psychological tests. From the data obtained the authors conclude that "foresight and judgment, as measured by performance on maze tests, are impaired when the subjects are deficient in the B vitamins and are improved after therapy with thiamin or with the B complex. General intelligence, reasoning ability (reading), and speed of hand muscle coordination (tapping) show no measurable deterioration when the subjects are deficient in the B vitamins and no improvement after therapy with thiamin or with the B complex.

**V. The normal requirement for thiamine; some factors influencing its utilization and excretion, K. O. Elsom, J. G. Reinhold, J. T. L. Nicholson, and C. Chornock.**—Observations were carried out to determine whether or not the minimal requirement of thiamin is accurately determined by the Cowgill formula. Six women were maintained on a diet containing thiamin slightly in excess of the theoretical requirements and three on essentially the same diet except for the B vitamins, which were given in amounts supplying approximately half of their theoretical requirements. The 24-hr. excretion of thiamin was determined in all cases. Of the six receiving the calculated theoretical requirements, three remained well and three developed symptoms of the deficiency. As the latter group were all of small body weight and consequently received less of the vitamin than the others, it is suggested that the influence of body weight on requirement is less important than suggested by Cowgill. The absolute thiamin intake compatible with health in these subjects was about 651  $\mu$ g. and the thiamin:calorie ratio about 0.35. The quantity of thiamin excreted varied appreciably from day to day independently of the volume of urine and was proportional to the intake but independent of the body weight. The excretion was lowered in one case in the presence of infection and returned to normal when the infection subsided.

**Choline deficiency in rats of various ages, R. W. ENGEL. (Ala. Expt. Sta.). (Soc. Expt. Biol. and Med. Proc., 50 (1942), No. 2, pp. 193-196).**—Weanling rats placed on a diet severely deficient in choline but otherwise adequate (E. S. R., 86, p. 420) were given choline chloride at levels of 4 or 5 mg. daily. While there was considerable individual as well as litter variation in the response of the animals, it appeared that about 5 mg. of choline chloride daily was necessary to prevent the fatal hemorrhagic kidney disease in weanling rats on a diet severely deficient in choline. The choline deficiency was produced within from 7 to 14 days at any time during the rapidly growing period when choline was omitted from the diet. Weanling rats kept on the stock diet for periods of 3 or 5 weeks were somewhat less susceptible to choline deficiency than rats fed the diet low in choline and supplemented with 20 mg. of choline chloride daily for similar periods.

**The relation of B-vitamins and dietary fat to the lipotropic action of choline, R. W. ENGEL.** (Ala. Expt. Sta.). (*Jour. Nutr.*, 24 (1942), No. 2, pp. 175-185).—"When thiamin, riboflavin, pantothenic acid, pyridoxin, corn oil, and choline were fed to rats receiving a purified diet containing 18 percent of casein for a 3-week experimental period, an abnormal accumulation of liver fat resulted. Under these conditions 2 mg. of choline chloride per rat daily failed to prevent the kidney hemorrhages of choline deficiency; at least 10 mg. of choline chloride was necessary for this factor to exert its maximum lipotropic action, but normal liver-fat levels were still not obtained. The addition of 3 mg. of inositol per rat daily to the diet adequate in choline and containing the above B vitamins reduced the liver fat to the normal level found in rats receiving an adequate stock diet. Prolonged feeding of a diet deficient in pyridoxin or essential fatty acids resulted in fatty livers, even though the diet contained adequate choline. It is concluded that pyridoxin and a source of essential fatty acids are necessary in the diet for choline to function properly as a lipotropic agent. Inositol, in addition to choline, is a necessary dietary constituent for the rat receiving purified diets supplemented with the other B vitamins known to be required by this species."

**Enrichment of white bread with vitamin B complex through the addition of debitterized brewers' yeast, R. SCHWARZ, S. and L. LAUFER, and M. W. BRENNER** (*Indus. and Engin. Chem.*, 34 (1942), No. 4, pp. 480-483, fig. 1).—A commercial dry, debitterized brewers' yeast at levels of 2.5, 5.0, and 7.5 percent (in terms of bread solids) was incorporated in doughs of white breads which were prepared and scored by an experienced baking laboratory. The bread with the 2.5 percent yeast was equal in quality to the control made with no addition of brewers' yeast, but additions of increasing amounts of the yeast exerted some unfavorable influences on the bread quality. The 2.5-percent yeast bread contained 1.50, 0.879, 6.92, and 2.10 mg. of thiamin, riboflavin, nicotinic acid, and pantothenic acid, respectively, per pound of bread as received (37.3 percent moisture). The corresponding values for the control bread with no brewers' yeast were 0.168, 0.451, 2.76, and 1.64 mg. per pound. These values agreed within the limits of experimental error with those obtained by calculation from the analytical values for the bread ingredients.

Three commercial breads, representing ordinary white bread, enriched white bread, and a special process bread believed to be baked from the flour prepared by the flotation process, were analyzed and found to contain, respectively (on a per pound basis as received), 0.361, 1.05, and 1.47 mg. of thiamin, 0.386, 0.406, and 0.820 mg. of riboflavin, 3.31, 6.23, and 15.1 mg. of nicotinic acid, and 1.66, 1.81, and 2.40 mg. of pantothenic acid. It is suggested on the basis of the present tests that consideration should be given to the addition of dried debitterized brewers' yeast to flour for the purpose of fortifying baked goods with vitamin B complex.

**The effects of biotin upon fat synthesis and metabolism, G. GAVIN and E. W. MCHENRY** (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 619-625, fig. 1).—Evidence is presented, following similar methodology to that of an earlier study (E. S. R., 84, p. 700), suggesting that biotin is the active factor in the alcohol-soluble fraction of beef liver responsible for the formation in the rat of fatty livers containing a high cholesterol content (E. S. R., 85, p. 413).

**Synthesis of vitamin B<sub>1</sub> by yeast, J. M. VAN LANEN, H. P. BROQUIST, M. J. JOHNSON, I. L. BALDWIN, and W. H. PETERSON.** (Wis. Expt. Sta.). (*Indus. and Engin. Chem.*, 34 (1942), No. 10, pp. 1244-1247).—Several strains of yeast were used, the one employed in most of the experiments and best able to synthesize thiamin from the intermediates being a strain from commercial high-

thiamin bakers' yeast. The yeasts were maintained on a basic medium sterilized by a method described and composed of beet molasses, steep water, diastatic malt extract, diammonium phosphate, and distilled water. With the addition of synthetic thiamin to an aerated suspension of the growing or resting yeast cells, most of the thiamin was taken up by these cells. If the amount of thiamin present was in excess of the quantity necessary to raise the yeast to about 3 mg. per gram, a large part of the thiamin was not absorbed; however, by the addition of very large amounts of thiamin to the medium, yeast containing 6 mg. of thiamin per gram could be produced. When yeast was grown in the presence of the pyrimidine and thiazole portions of the thiamin molecule, thiamin was synthesized by the yeast. The efficiency of the conversion was from 70 to 90 percent provided the thiamin content of the yeast did not rise above 800  $\mu$ g. per gram. In yeast grown without aeration, the efficiency of conversion was low. Nonproliferating yeast cells, under aeration, converted pyrimidine and thiazole into thiamin almost quantitatively. The presence of spent wort was beneficial. The pyrimidine portion of thiamin was more readily synthesized by yeast than the thiazole portion. None of a large number of compounds tested was able to replace either pyrimidine or thiazole in thiamin synthesis by yeast.

**The nicotinic acid content of cereal products,** J. M. THOMAS, A. F. BINA, and E. B. BROWN (*Cereal Chem.*, 19 (1942), No. 2, pp. 173-180).—Nicotinic acid was determined by the method of Bina et al. (*E. S. R.*, 87, p. 13). Ash, protein, and moisture were also determined in most of the materials analyzed. The nicotinic acid content of a typical Kansas winter wheat mix (6.01 mg. per pound) was only 62.9 percent of that of a typical spring wheat mix (9.56 mg. per pound). From analyses and data on milling yields of the mill fractions of the spring wheat mix, it was determined that the patent and first and second clear flours combined contained approximately one-third and the mill feeds approximately two-thirds of the nicotinic acid of the wheat. The percentage of the wheat vitamin in the individual mill products increased as the ash content increased; bran, with a nicotinic acid content of 31.22 mg. per pound, contained the largest proportion (30.66 percent). In a series of cereal and legume seeds, spring wheat and soybeans, containing, respectively, 10.83 and 10.04 mg. of the vitamin per pound of dry solids, were the richest in nicotinic acid, while oats contained the lowest amount (3.66 mg. per pound of dry matter) and corn almost the same (3.70 mg.). Whole-wheat flours showed less nicotinic acid (6.23-7.44 mg. per pound) than ground whole wheats, indicating some refinement in the course of the milling. The nicotinic acid content of whole-wheat bread (4.08-5.25 mg. per pound, 34 percent moisture basis) was above that in white bread (1.90-2.42 mg.), but considerably below that in enriched white bread (8.50-9.96 mg.). Bakers' yeast and enriched bakers' yeast contained, respectively, about 55-60 and 550 mg. of nicotinic acid per pound, 70 percent moisture basis.

**Studies in nicotinic acid metabolism.**—V, A test for nicotinic acid deficiency in man, W. A. PERLZWEIG, H. P. SARETT, and L. H. MARGOLIS (*Jour. Amer. Med. Assoc.*, 118 (1942), No. 1, pp. 28-30, fig. 1).—The test consists essentially in determining the 24-hr. excretion of nicotinic acid and trigonelline before and after the ingestion of a 500-mg. test dose of nicotinamide. The subjects are instructed to omit for 3 days before the test all coffee and all leguminous vegetables and nuts because of their trigonelline content. The nicotinic acid content of the urine is not affected significantly by the test dose of nicotinic acid, but the trigonelline content of the urine is proportional to the adequacy of the nicotinic acid. In the cases studied 24 normal subjects gave an extra excretion of trigonelline under the conditions described amounting to 90 mg., 53 rather undernourished subjects from a N. Y. A. rehabilitation camp 63, and a group of

63 miscellaneous hospital subjects 41 mg. The authors had the technical assistance of M. Stenhouse and F. Spilman.

**Nicotinic acid, pantothenic acid, and pyridoxine in wheat and wheat products**, L. J. TEPLY, F. M. STRONG, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Nutr.*, 24 (1942), No. 2, pp. 167-174).—Fifty-five samples of wheat varying as to variety and source were assayed for nicotinic acid by the microbiological method of Snell and Wright (E. S. R., 87, p. 12) applied to autoclaved NaOH treated suspensions of the samples, for pantothenic acid by the microbiological method of Strong, Feeney, and Earle (E. S. R., 86, p. 588) applied to autoclaved water suspensions of the samples, and for pyridoxin determined by the biological method of Conger and Elvehjem (E. S. R., 86, p. 427). Values for these three vitamins, respectively, expressed in micrograms per gram, averaged 59  $\mu$ g. (range 47-106  $\mu$ g. per gram), 13.3 (9.1-17.5), and 4.6 (3.2-6.3  $\mu$ g.). Patent flour, clear flours, and wheat germ were also assayed for these vitamins. Patent flour compared with whole wheat contained about one-sixth as much nicotinic acid and about one-half as much pantothenic acid and pyridoxin.

**Riboflavin content of some common foods**, H. E. MUNSELL. (*Food Res.*, 7 (1942), No. 2, pp. 85-95).—Riboflavin was determined by a rat-growth method in which the animals were brought to a constant or declining weight on a riboflavin-free diet and then divided into four groups of litter-mate animals of comparable weight. To these were allotted, respectively, supplements of pure riboflavin (3  $\mu$ g. per rat per day) and of the test substance at three different levels estimated as sufficient to furnish 3  $\mu$ g., less than 3 but more than 1  $\mu$ g., and more than 4 but less than 8  $\mu$ g. of riboflavin per rat per day. After a 3- or 4-week test period, the average gains in weight of the three assay groups plotted against the amounts of test material fed as a daily supplement gave a curve from which was read the amount of test material corresponding to the average gain in weight of the control animals receiving the 3- $\mu$ g. supplement of riboflavin.

The values obtained for the riboflavin content of 20 food items, purchased in small quantities periodically from local retail stores, together with data obtained by other investigators, are summarized. The foods, described briefly as to the nature of the samples, were representative of the different food groups. The highest value for riboflavin content (545-600  $\mu$ g. per 100 gm.) was obtained for Cheddar cheese, followed by that for dried navy beans (300-324  $\mu$ g.), and eggs (306-320  $\mu$ g.). Beef, pork, and fish (salmon) muscle, and milk each assayed more than 200  $\mu$ g. per 100 gm. Among the green leafy vegetables, spinach and the leaves of broccoli gave very high values (371-460  $\mu$ g.); green peas (200  $\mu$ g.), endive (187-214  $\mu$ g.), and green string beans (107-115  $\mu$ g.) were next in order; and green winter cabbage (38  $\mu$ g.), green peppers (30  $\mu$ g.), and Iceberg or New York type lettuce (less than 25  $\mu$ g.) were low. Roots and tubers were uniformly low (25-71  $\mu$ g. per 100 gm.), and the whole cereals (whole wheat and rolled oats) were intermediate (100  $\mu$ g. per 100 gm.).

**Thiamin retention in self-rising flour biscuits**, R. A. BARACKMAN (*Cereal Chem.*, 19 (1942), No. 1, pp. 121-128; *abs. in Northwest. Miller*, 209 (1942), No. 10, Sect. 2, pp. 3a, 20a-21a, fig. 1).—The self-rising flour and biscuits were prepared essentially by official procedures (E. S. R., 86, p. 441), and thiamin was determined on the air-dried, ground biscuits by the thiochrome method. The tests involved the determination of the amount of added synthetic thiamin hydrochloride recovered in the baked biscuit irrespective of the native thiamin as determined in biscuits baked without the added vitamin. In accordance with the standards for enriched flour (E. S. R., 86, p. 552), the vitamin for the recovery tests was added to the flour at the level at 2.16 mg. per pound. Preliminary trials showed that the vitamin recovery was not affected by certain

variations in baking conditions and in methods of dough preparation. Biscuits of normal size resulted in 88-percent recovery, whereas only a 79-percent recovery was attained when the biscuits were thin and crusty. The thiamin content of the crust was found to be less than that of the crumb, the respective values obtained in one assay being 2.46 and 3.10  $\mu\text{g.}$  per gram of air-dried product. Overbaking to give deeply browned or burned crusts decreased thiamin recovery. Biscuits made with milk showed better thiamin retention than those made with water. Biscuits made from self-rising flours containing varying ratios of soda and phosphate showed thiamin recoveries in proportion to the acidity of the biscuits. Under conditions favorable to the optimum preservation of thiamin, that is, with the pH no greater than 7.1-7.2 during the baking process, from 80 to 85 percent of the added thiamin was retained. It was shown that modification of present standard self-rising flour formulas to include 0.25 percent of additional calcium acid phosphate (preferably the anhydrous type) would result in optimum retention.

**Thiamine, riboflavin, pyridoxine, and pantothenate deficiencies as affecting the appetite and growth of the albino rat,** L. VORIS, A. BLACK, R. W. SWIFT, and C. E. FRENCH. (Pa. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 6, pp. 555-566, fig. 1).—In this study of the effect of moderate deficiencies of single water-soluble vitamins on growth and on the appetite of young rats, the paired feeding technic (with equalized food intake) was used, one animal in each of 10 litter pairs for each test receiving a complete synthetic diet and the other the same diet except for the following reduced allowances of the specified vitamins: Thiamin 1  $\mu\text{g.}$ , riboflavin 1, pyridoxin 0.5, and calcium pantothenate 2  $\mu\text{g.}$  A similar comparison was made between the basal diet and the same diet plus 0.2 percent of liver extract. The experiment lasted for 10 weeks, during which time it was found necessary to increase somewhat the quantity of thiamin and of calcium pantothenate in the deficient diets.

All four vitamins had a definite but unlike effect on the appetite. "With insufficient thiamin the appetite of the rat would drop to submaintenance levels and the disinterest in eating would continue until additional thiamin was provided. With insufficient riboflavin the appetite depression appeared to be the result of a general physiological debility of an unspecific nature. With insufficient pyridoxin there were sudden and temporary lapses in appetite, followed by an equally prompt recovery. Pantothenate anorexia seemed to follow the pattern of riboflavin insufficiency." Food consumption of the female rats was reduced 27 percent for the low thiamin, 20 for riboflavin, 34 for pyridoxin, and 27 percent for calcium pantothenate. Growth curves for the paired animals in the thiamin comparison were practically parallel when both sexes were considered together, with the odds only 18 to 1 that thiamin had an effect on growth. However, the difference for the females was significant, with odds of 2,000 to 1. For the other vitamins the odds were 3,000 to 1 for riboflavin, 50 to 1 for pyridoxin, and 200 to 1 for pantothenic acid.

The authors conclude that riboflavin, pyridoxin, and pantothenic acid have specific growth-promoting effects unrelated to appetite and that this is also true for the thiamin in the case of females but not of males. Neither appetite nor growth was improved by the addition of liver extract to the basal diet.

**The occurrence of fits in pyridoxine deficient rats,** S. LEPROVSKY, M. E. KRAUSE, and M. K. DIMICK. (Univ. Calif. et al.). (*Science*, 95 (1942), No. 2465, pp. 331-332).—The findings of Chlcek et al. (*E. S. R.*, 85, p. 856) that epilepticlike fits may occur in pyridoxin-deficient rats are confirmed, and the possibility is suggested that disturbed water metabolism may be involved. It is noted that convulsions were never observed in animals under 4½ mo. of age and

then only rarely until from 6 to 8 mo., when they occurred more frequently and with gradually increasing duration.

**A convulsive syndrome in young rats associated with pyridoxine deficiency.** E. P. DANIEL, O. L. KLINE, and C. D. TOLLE (*Jour. Nutr.*, 23 (1942), No. 3, pp. 205-216).—A convulsive syndrome, previously (E. S. R., 80, p. 562) shown to occur in young rats during the suckling stage when nursed by mothers on the basal diet used in the U. S. P. method of assay for thiamin (E. S. R., 85, p. 152) supplemented with thiamin, has been shown to be a specific result of pyridoxin deficiency.

The syndrome was cured or prevented by the administration of crystalline pyridoxin to the young. When suckling young of mothers on a stock diet were transferred to lactating rats on the deficient diet a rapid depletion of pyridoxin reserves was obtained, as was also the case when the mothers were transferred during lactation from a stock diet to one deficient in pyridoxin. No injury was observed in females maintained on pyridoxin-restricted diets through pregnancy and lactation, and there was no failure in lactation, although the pyridoxin content of the milk was reduced to such an extent that the convulsive syndrome developed in the young. Attention is called to the similarity in symptoms of pyridoxin deficiency in rats with those reported by Chick et al. in young pigs (E. S. R., 82, p. 663) and in mature rats (E. S. R., 85, p. 856) maintained on synthetic diets deprived of pyridoxin.

**Vitamin C, carotene, calcium, and phosphorus in expressed vegetable juice.** M. E. PUFFER, W. F. HINMAN, H. CHARLEY, and E. G. HALLIDAY (*Food Res.*, 7 (1942), No. 2, pp. 140-143).—Juices from a number of vegetables were expressed with a metal hand-turned juicer of an inexpensive type being sold for home use. The juicing time was in general from 3 to 5 min. for from 2 to 4 oz. of juice, and the yields were as follows: Celery 57-71 percent, cabbage 50-78, green beans 40-48, spinach 35-58, and carrots 20-33 percent. The juices were unattractive in color and in flavor. Determinations made on the vegetables and on the juices showed that the freshly expressed juices contained from 8 to 69 percent of the reduced ascorbic acid, from 22 to 36 percent of the carotene, from 15 to 90 percent of the calcium, and from 24 to 62 percent of the phosphorus of the whole vegetable. Much of the nutritional value of the vegetable would thus be lost if only the juice were used. Weight for weight, however, the juices were almost as good sources of the nutritional elements as were the whole vegetables. In none of the juices studied was there any loss of carotene upon standing, but the reduced ascorbic acid content was appreciably decreased.

**The ascorbic acid (vitamin C) content of rhubarb.** E. N. TODHUNTER (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 437-440).—Hothouse and field-grown rhubarb of two varieties received at the stage of prime maturity for harvesting was analyzed over two seasons for ascorbic acid content by the method of Bessey (E. S. R., 82, p. 14) for the Evelyn photoelectric colorimeter. These analyses were made on composite samples of center sections from several stalks. Analyses were also made of cooked samples of rhubarb, using the whole stalks sufficient to give 450 gm., and baking these, after sectioning and covering with sirup, in a covered Pyrex dish at 350° F. for 30 min. Sections from stem and leaf ends of other fresh stalks of these same varieties were also analyzed. A summary of the data from the various determinations showed the ascorbic acid content of fresh rhubarb grown in the hothouse to range from 3.5 to 5.8 mg. per 100 gm. for the Victoria variety and from 5.8 to 6.7 mg. for the Wine variety. The field-grown product contained from 6.8 to 8.0 mg. for the Victoria variety and from 6.5 to 16.7 mg. per 100 gm. for the Wine variety.

The leaf end of the rhubarb stalk was higher in ascorbic acid than the stem end. The cooked rhubarb of the Wine variety averaged 5.0 and 4.3 mg. ascorbic acid per 100 gm. for the hothouse and field-grown lots, respectively; corresponding values for the Victoria variety were 2.4 and 4.5 mg., respectively. When these values were calculated to the fresh weight basis, with due allowance for added water and sugar, it was apparent that there had been practically no destruction of ascorbic acid in the process of baking the rhubarb in a covered dish.

**Effect of mineral nutrition on the ascorbic-acid content of the tomato,** K. C. HAMNER, C. B. LYON, and C. L. HAMNER. (U. S. D. A.). (*Bot. Gaz.*, 103 (1942), No. 3, pp. 586-616, figs. 13).—In four experiments with the Bonny Best variety in sand culture, growth and fruitfulness could be correlated with minor variations in nutrients. The gross appearances of plants grown in 87 different solutions are discussed, and quantitative data are reduced and analyzed statistically. In general, variations in Ca and nitrate produced greater differences in growth and fruitfulness over wider ranges of concentrations than were obvious with the other elements. Interactions of the effects of various elements were noted. The ascorbic-acid content of the fruit was significantly higher in some sulfate-deficient treatments and significantly lower in K and phosphate deficiencies than average values. Except for these cases, no demonstrable effects of mineral supply on ascorbic acid were observed. Plants grown during fall and winter produced fruit with about one-half as much ascorbic acid as those grown during summer. The location where the plants were grown affected the ascorbic-acid content of the fruit, but these effects could not be correlated with differences among the soils and appeared to be associated with environal differences at the top of the plants. Significant positional effects on ascorbic-acid content, even in a relatively small trial plot, were observed. Plants grown in sand culture supplied with a balanced nutrient solution produced fruit as high (or higher) in ascorbic acid as that obtained on good soil. Several other observations are included on the effects of variations in mineral nutrition on growth and fruitfulness and of environal influences on the ascorbic-acid content, and a discussion of the possible practical significance of the results is included.

**The influence of diet on the ascorbic acid requirement of premature infants,** M. DANN. (Cornell Univ.). (*Jour. Clin. Invest.*, 21 (1942), No. 2, pp. 139-144, fig. 1).—Ascorbic acid saturation tests were given to two groups of 11 premature infants each. The subjects in one group receiving boiled breast milk gave ascorbic acid plasma values ranging from 1.3 to 3.5, with an average of 1.9 mg. percent 4 hr. after a test dose of either 100 mg. of ascorbic acid intramuscularly or 200 mg. by mouth. The values for the other group, which received artificial formula feedings, ranged from 0.1 to 1.6, with an average of 0.8 mg. percent. In explanation of the higher degree of saturation of ascorbic acid in the tissues of the infants receiving human milk, the suggestion is made that an increased daily requirement for vitamin C is related to the higher content of protein in cow's milk. It is estimated that the amount of milk given to these infants would furnish from 2.6 to 2.8 gm. of protein per kilogram of body weight in the human milk and from 4.6 to 6.1 gm. per kilogram in the cow's milk. Attention is called to evidence in the literature that ascorbic acid is concerned with the intermediary metabolism of aromatic amino acids.

**The daily intake of ascorbic acid required to maintain adequate and optimal levels of this vitamin in blood plasma,** M. L. FINCKE and V. L. LANDQUIST. (Oreg. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 5, pp. 483-490).—In this study, in which the authors had the technical assistance of P. M. Carpenter, a plasma ascorbic acid level of 0.8 mg. per 100 cc. was taken as the criterion for an adequate state of nutrition with respect to vitamin C, and the daily require-

ment to meet this criterion was determined for five college students, with results of 38–49, 49, and 61 mg., respectively, for the three women and 69 and 89 mg. for the two men subjects. These values corresponded to daily ascorbic acid intakes of from 0.8 to 1.2 mg. per kilogram body weight, with an average of  $1.0 \pm 0.14$  mg.

In determining the requirements for tissue saturation two criteria were tested—(1) the lowest excretion in 24 hr. after a test dose of 400 mg. when the subject was known to be in saturation as determined by the method of Belser et al. (E. S. R., 82, p. 428), and (2) the lowest blood plasma level when the subject was in known saturation. In testing four women subjects by these criteria, the first proved unsatisfactory, for in only one instance did the excretion of ascorbic acid in response to the test dose parallel the previous intake. The second criterion proved more satisfactory, and the amounts of ascorbic acid required to meet this criterion in three of the women subjects were 111, 111, and 131 mg., respectively, or 1.7, 1.8, and 2.0 mg. per kilogram body weight.

**The rate of increase of blood plasma ascorbic acid after ingestion of ascorbic acid (vitamin C),** E. N. TODD HUNTER, R. C. ROBBINS, and J. A. MCINTOSH. (Wash. Expt. Sta. et al.). (*Jour. Nutr.*, 23 (1942), No. 3, pp. 309–319, fig. 1).—The course of ascorbic acid in blood plasma following the ingestion of 50 mg. of ascorbic acid from different sources and as influenced by various factors was studied in five college women. Blood samples were taken just before and 15 and 30 min. after a breakfast of toast and coffee with the given supplement and at half-hour intervals thereafter through noon, with determinations for each supplement on 3 different days.

The ascorbic acid of the plasma began to rise within from 30 to 60 min. following the ingestion of the supplement and returned to the fasting level in from 3 to 4 hr. The maximum increase took place within  $1\frac{1}{2}$  hr. for crystalline ascorbic acid, orange juice, and orange sections, in 2 hr. for strawberries, and in  $2\frac{1}{2}$  hr. for raw cauliflower. The same subjects showed the same general picture of absorption rates in three separate tests, and for four of the subjects of different height and weight there was close agreement in the absorption rate and time of reaching the maximum values. Iron salts in the form of 6 gr. of ferrous sulfate or an equivalent amount of iron as ferric ammonium sulfate taken at the same time as the 50-mg. dose of ascorbic acid had no effect on the plasma ascorbic acid in two subjects and a slight delaying effect in one. A high-fat intake (50 gm. of butter) was without effect. Low fasting levels of ascorbic acid decreased the amount but not the time of increase in plasma levels following the test dose. At a fasting level of 0.5 mg. or less per 100 cc. of plasma there was no increase following the ingestion of 50 mg. of ascorbic acid. When the intake was raised to 400 mg., there was a greater increase in plasma concentration and a longer time elapsed before return to the original fasting level.

**The relation between plasma and dietary ascorbic acid,** A. H. BRYAN, D. F. TURNER, R. L. HUENEMANN, and G. LOTWIN (*Amer. Jour. Med. Sci.*, 202 (1941), No. 1, pp. 77–83, figs. 2).—Scatter-point diagrams of daily ascorbic acid intakes per kilogram body weight (estimated partly from food composition tables and partly from original data) plotted against fasting blood plasma ascorbic acid levels are given in two charts—one covering 41 correlations for 36 individual subjects and the other these same correlations plus 24 others on 20 additional subjects whose dietary records were less accurate than those in group 1. The charts, particularly the first, show a more or less linear relationship between the dietary intakes and plasma ascorbic acid levels until they approximate from 1.7 to 1.9 mg. per kilogram body weight and 1.0 mg. per 100 cc. plasma, respectively. On plotting the plasma levels against daily ascorbic acid intakes both per square meter of body surface and per 100 calories of calculated basal metab-

olism, similar correlations were obtained, but the total average ascorbic acid intakes without reference to body weight plotted against plasma levels gave a wide scatter of points. It is concluded that the daily intake of ascorbic acid necessary to stabilize a normal individual at a given level of plasma concentration may be predicted, and that the determination of the fasting plasma ascorbic acid affords a useful objective method of characterizing the diet of the normal individual in regard to previous vitamin C intake.

**The oral ascorbic acid tolerance test and its application to senile and schizophrenic patients,** E. SIOZ, B. M. SHINNERS, and R. A. CHITTICK (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 4, pp. 518-526, figs. 4).—In the test recommended a blood sample is taken fasting, preferably in the morning, a test dose of ascorbic acid in amounts of 6 mg. per kilogram body weight is given, and blood samples are again taken at intervals up to 5 hr. All of the samples are analyzed for ascorbic acid, and the data are plotted as curves of ascorbic acid against time. A breakfast of a cup of coffee and plain toast may be taken after the test dose.

On the basis of 60 such determinations and changes produced with supplementary feeding and deprivation of ascorbic acid, the authors suggest four degrees of relative saturation—saturated, high normal, low normal, and under-saturated. Type I or saturated curves are characterized by a high initial value (about 1 mg. per 100 cc. or over), a moderate rise following a test dose, and a failure to return to the initial level; type II by variable initial levels (from about 0.35 to 1 mg.), a marked rise in all cases, and variations in the rate of fall; type III by relatively low fasting levels (0.35-0.7 mg. per 100 cc.), only slight rises following the test dose, and return to the original level by the fifth hour; and type IV by no rise following the test dose. It was found possible to change the curves from type I<sub>1</sub> to type IV and the reverse, respectively, by ascorbic acid deprivation and by daily administration of large amounts of ascorbic acid over considerable periods of time. Type IV curves were found for five senile patients, and all were changed to type I by the administration of 200 mg. of ascorbic acid daily for 2 weeks. The deficiencies in these subjects were attributed to senility rather than old age, as other elderly patients on the same diet but not showing signs of senility had normal values. It is suggested that extra ascorbic acid be given to senile patients. In a group of 20 schizophrenic patients no indications of vitamin C deficiency were found.

**Ascorbic acid excretion at known levels of intake as related to capillary resistance, dietary estimates, and human requirements,** T. LEVCOWICH and E. L. BATCHELDER. (R. I. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 4, pp. 399-408).—In an extension of earlier studies reported by Mitchell et al. (*E. S. R.*, 81, p. 148), comparisons were made of the range of 24-hr. urinary ascorbic acid excretion of college women students on their customary freely chosen diets with that of a group of students maintained, after a saturation period, on a basal diet furnishing only 5 mg. of ascorbic acid and supplemented with 50 mg. of ascorbic acid daily. The values for the latter group ranged from 17 to 29, with an average of 22 mg. Of the 56 determinations in the former group, 27 came within the same range. Calculations of the ascorbic acid content of the diets of these subjects, however, gave estimated intakes of from 44 to 253, with an average of 121 mg. daily. Inasmuch as the excretion values of these presumably healthy subjects were in the same range as the excretion on 50 mg. of ascorbic acid, the authors conclude that 50 mg. may be considered the minimal requirement of ascorbic acid for moderately active young women, but suggest a safety factor of 50 percent. They point out, moreover, that the calculated ascorbic acid content of the foods in a freely chosen diet tends to

be overestimated and may lead to a false sense of security as to vitamin C intake.

Capillary fragility tests were made on two of the subjects during the last 3 days of each test period following different levels of ascorbic acid intake. Although the capillary resistance was not significantly affected by variation in the ascorbic acid intake over an extended period of time, the petechiae became larger in size, although not changing in number. This is thought to suggest that the vitamin C-free diet used may have been lacking in vitamin P or some other factor affecting capillary fragility.

**Vitamin C and wound healing.**—I, **Experimental wounds in guinea pigs.** II, **Ascorbic acid content and tensile strength of healing wounds, in human beings,** M. K. BARTLETT, C. M. JONES, and A. E. RYAN (*New England Jour. Med.*, 226 (1942), No. 12, pp. 469-473, figs. 3; pp. 474-481, figs. 9).—In the first part of this investigation the concentration of ascorbic acid in healing wounds in guinea pigs was determined under a variety of dietary conditions and correlated with the tensile strength of these wounds. The dietary conditions included (1) preoperative (2 weeks) and postoperative low vitamin C, (2) preoperative and postoperative high, (3) preoperative low and postoperative high, and (4) preoperative high and postoperative low vitamin C. At the time of operation biopsy material was analyzed for ascorbic acid in comparison with the later autopsy material.

In (1) the biopsy and autopsy tissues were both low in ascorbic acid, with no increase in the healing wound; in (2) both were high, with a marked increase in the healing wound; in (3) the biopsy material was low and the autopsy high; and in (4) the biopsy material was high and the autopsy not much higher than in (1). The tensile strength of the wounds examined 10 days postoperatively was much greater in those with a high than a low vitamin C content.

It is concluded that in these animals the tissue levels of ascorbic acid resulting from the preoperative administration of vitamin C are of much less importance in establishing optimum ascorbic acid of the healing wound than vitamin C intake during postoperative treatment.

In part 2 information was sought to supplement the work of Crandon, Lund, and Dill (*E. S. R.*, 86, p. 871) on the value of vitamin C in wound healing in human beings by means of direct observations on the tensile strength of healing wounds and a correlation of these with the tissue and plasma ascorbic acid content. The studies were carried out on five patients operated on for unilateral hernia and one for bilateral hernias. During the preoperative period the patients received the equivalent of 100 mg. of ascorbic acid daily in the hospital diet, and supplemental ascorbic acid was given to some before and after the operation. Plasma ascorbic acid and 24-hr. urinary excretion were determined throughout the period, and samples of the skin and fasciae were taken for analysis before and 10 days after the operation. The subject with bilateral inguinal hernias afforded an opportunity for contrasting ascorbic acid treatment in the two operations. In the first no ascorbic acid was given postoperatively and in the second 1,000 mg. daily was given. In the first group the control biopsies of the fasciae gave ascorbic acid values from 0.11 to 0.48, with an average of 0.25 mg. per 100 gm., and the skin biopsy material an average value of 1.35 mg. The healing fascia values ranged from 3.83 to 7.65 mg. per 100 gm., with an average of 6.01 mg. The tensile strength of the fasciae varied from 1,100 to 2,400, with an average of 1,600 gm. The subject with bilateral hernias had the following values in connection with the operation without and with additional ascorbic acid, respectively: Preoperative plasma ascorbic acid 0.09 and 0.07 mg. per 100 cc., control biopsy material 0.0 and 0.0,

10-day-old scar tissue 0.67 and 6.77 mg. per 100 gm., and tensile strength 400 and 1,200 gm. This evidence indicates that "in spite of a low plasma ascorbic acid level at the time of operation, normal wound healing may be produced by adequate vitamin C therapy during the postoperative period."

**Criteria of response in the bio-assay of vitamin E, K. E. MASON** (*Jour. Nutr.*, 23 (1942), No. 1, pp. 59-70).—The studies reported concern the attempts to evaluate recognized gradations in negative and positive responses to vitamin E administration, based upon the number of live fetuses and the weight of the uterine contents on the sixteenth day of pregnancy, in assay tests on 600 rats. The results were not much superior to those obtained by treating responses as an "all or none" type, except for the recognition of a subminimal type of response otherwise classed as negative. The presence of two or more viable fetuses in utero at the sixteenth day of pregnancy afforded, however, a criterion of response essentially equivalent to, and in some cases more reliable than, that based upon delivery of progeny at term. Examination of the uterus at the sixteenth day gave information especially pertinent to critical levels of response and prevented misinterpretation of certain atypical uterine states as negative responses to dose.

**Distribution of vitamin E in the tissues of the rat, K. E. MASON** (*Jour. Nutr.*, 23 (1942), No. 1, pp. 71-81).—A total of 338 bio-assay tests were conducted on tissues of rats receiving approximately 4, 100, and 10,000 times the minimal daily requirement of vitamin E. At the low (suboptimal) intake, the heart, lung, and spleen contained almost twice as much vitamin E per gram of fresh tissues as did the muscles, body fat, and other visceral organs, and about 4 times as much as the liver. At moderately high levels of intake the storage in the viscera, muscles, and body fat was increased from 3 to 4½ times, with the heart, lung, and spleen receiving more than other tissues, and with the amount in the liver being increased about 11 times. The mammary gland concentrated about twice as much E as the liver. At excessively high levels of intake the muscles and liver, respectively, showed about 12 and 150 times the vitamin E storage observed at the low level of intake. The liver content of the vitamin afforded the most useful measure of the previous intake and storage. The total storage of vitamin E in the rat body represented but a small fraction of that ingested.

**Symposium on fortified food** (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 3, pp. 324-351, *figs.* 4).—At this symposium, held at the 1942 meeting of the American Institute of Nutrition, the following topics were reviewed: Definitions and Standards of Identity for Food, by E. M. Nelson (pp. 321-327); Food Consumption Studies and Dietary Recommendations, by H. K. Stiebeling (pp. 327-330) (U. S. D. A.); Clinical Observations Bearing on Food Requirements, by E. S. Gordon (pp. 330-335) (Univ. Wis.); Guiding Principles for the Fortification of Foods, by F. C. Bing (pp. 336-342); and The Laboratory Control of Enriched Foods, by B. L. Oser (pp. 343-351). Numerous references to the literature are cited in the three latter reviews.

**The fortification of foods, A. F. MORGAN**. (Univ. Calif.). (*Med. Woman's Jour.*, 49 (1942), No. 4, pp. 145-150).—This discussion deals with the classes of vitamins and vitaminized products, namely, synthetic vitamins, concentrates, concentrates plus crystalline vitamins, naturally rich products not usually used as foods, natural products plus concentrates or synthetic vitamins, and processed foods to which vitamins are added to restore them to their original level. Also considered are standards and units of the several vitamins; arguments for, and the advantages of, use of fortification in foods and the use of vitamin pills and

concentrates v. a diet of natural foods; and the disadvantages in the use of fortified food and vitamin pills.

**Combating dietary deficiencies with enriched and fortified foods, E. J. LEASE, R. C. RINGROSE, and J. G. LEASE (*South Carolina Sta. Cir. 62 (1942), pp. 8*).**—It is pointed out that fortification of staple foods offers exceptional promise in the South as a means of combating the vitamin and mineral deficiencies of the diet of a considerable percentage of the population. This existing malnutrition is due to fixed eating habits, limited educational advancement, and low economic status of these people; to the lowered nutritional value of foods produced on soil of low fertility; and to other conditions. Increased cost of living, shortage of labor, shortage of commercial fertilizers, and relatively high prices for cotton, all prevailing at present, tend to limit the variety of foods for many people and to result in an even less adequate diet. In the past these conditions have increased the incidence of pellagra. It seems important, therefore, for the duration of the war at least, to fortify staple foods consumed in large quantities by the masses of people as a means of eliminating certain nutritional deficiencies. Because of large-scale production, the cost of certain synthetic vitamins has been reduced to the point where their use for such fortification is feasible. State legislation requiring the enrichment of bread and flour and the fortification of margarine has been enacted in South Carolina and Louisiana in order to obtain widespread enrichment of these staple foods. It is pointed out that, for the South in particular, the enrichment of corn meal and grits would bring about further improvement in the nutritional status of many people consuming restricted diets.

**Symposium on deficiency diseases (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.], 1 (1942), No. 3, pp. 292-323, figs. 7*).**—The following topics were reviewed, with numerous references to the literature: Some Specific Physiological Disturbances Induced by Marginal Vitamin Deficiencies (C and B<sub>1</sub>), by C. G. King (pp. 293-296); Foods as Sources of the Vitamins, by F. C. Bing (pp. 296-303); The Biological Action of the Vitamins, by C. A. Elvehjem (pp. 304-309) (Univ. Wis.); Vitamins as Pharmacological Agents, by H. Molitor (pp. 309-315); Vitamins in the Practice of Medicine, by N. Jolliffe and R. Goodhart (pp. 313-319); and Vitamins and Public Health, by W. H. Sebrell (pp. 319-323).

**The prevalence of malnutrition, N. JOLLIFFE, J. S. McLESTER, and H. O. SHERMAN (*Jour. Amer. Med. Assoc., 118 (1942), No. 12, pp. 944-950*).**—In this evaluation of existing evidence on the prevalence of malnutrition in the United States, the terms nutritional failure, dietary inadequacy, nutritional inadequacy, and malnutrition are first defined, following which evidence is summarized of three kinds—(1) food consumption records or dietary surveys, (2) official death rates and hospital admission figures, and (3) medical assessments of the nutritional status in samples of the population. For purposes of comparison the material summarized is tabulated, with accompanying literature references on gross evidences of malnutrition, prevalence of secondary (iron deficiency) anemia, and prevalence of ascorbic acid depletion. "The evidence at our disposal warrants the conclusion that dietary inadequacies and malnutrition of varying degrees are of frequent occurrence in the United States, and that the nutritional status of an appreciable part of the population can be distinctly improved. If optimal nutrition is sought, not mere adequacy, then widespread improvement is possible."

**Diseases of nutrition: Review of certain recent contributions, H. R. BUTT, W. V. LEARY, and R. M. WILDER (*Arch. Int. Med., 69 (1942), No. 2, pp. 277-343*).**—This review, covering the literature of 1941 with a few late 1940 references, is devoted almost entirely to the vitamins, which are considered as to their

chemical and physiological properties, methods of measuring the specific deficiency, and role in health and disease, including clinical uses. The literature references, numbering over 300, are given as footnotes. The review closes with a discussion of the work of the Committee on Food and Nutrition of the National Research Council and the National Nutrition Conference for Defense, the final recommendations for which are listed.

**The antirachitic effectiveness of fall and winter sunshine, G. C. WALLIS.** (S. Dak. Expt. Sta.). (*S. Dak. Acad. Sci. Proc.*, 21 (1941), pp. 44-46).—In a study of vitamin D deficiency of dairy cattle, cows were depleted by early or late fall, at which times they were turned out for sunshine. With this change in management, the severe physical symptoms showed marked improvement in from 2 to 4 days, the low levels of blood calcium increased to normal in about 2 weeks, the negative calcium and phosphorus balances became positive and were maintained, and the vitamin D content of the butterfat, which was too low to be detected before sunshine exposure, increased to 0.20 International Unit per gram following exposure. This evidence, obtained in observations on three cows, supports the conclusion that the antirachitic effectiveness of late fall and winter sunshine may be more significant than previous observations and physical measurements of the amount of ultraviolet light reaching the earth's surface at this season might indicate.

**Pantothenic acid absorption in pernicious anemia, C. E. MEYER, I. F. BURTON, and C. C. STURGIS** (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 363-365).—In seven patients with pernicious anemia the pantothenic acid excretion, as determined in repeated tests before and after oral administration of 100 mg. of calcium pantothenate, averaged 4.4 and 13.1 mg. per 24 hr. These excretions were slightly but probably not significantly less than the corresponding excretions of 6.1 and 18.4 mg. by healthy individuals studied in the same manner. "This indicates there is no impairment of absorption of this compound in patients with pernicious anemia with which is always associated achlorhydria. The possibility must be considered, however, that the lack of hydrochloric acid may make the pantothenic acid in food less available for absorption."

**Red staining of paws and whiskers as in vitamin B<sub>2</sub>-complex deficient rats after dehydration, S. G. SMITH** (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 691-693, fig. 1).—An earlier study of Smith and Sprunt (*E. S. R.*, 75, p. 888) suggesting that the red staining of the paws and whiskers of rats on diets deficient in some constituents of the B complex is related to dehydration, with later confirmation by Figge and Atkinson (*E. S. R.*, 87, p. 600), has been extended, with the technical assistance of T. E. Lasater, to determine if the B vitamins fed singly or together are capable of altering the course of development of these lesions resulting from dehydration. Two groups were fed Purina Dog Chow without water; five groups, the same supplemented with pantothenic acid (two groups), riboflavin, all of the B vitamins, and brewers' yeast, respectively; and three groups, water with no food. In all of the animals deprived of water, the accumulation of red porphyrin material began to appear on the third day and tended to increase progressively. The administration of riboflavin and pantothenic acid had no appreciable, and of the combination of synthetic vitamins or brewers' yeast only a minimal, effect. However, it is thought probable that these vitamins, particularly pantothenic acid and riboflavin, are concerned with water metabolism.

**Nutrition as it affects tooth decay, J. D. BOYD** (*Jour. Amer. Dietet. Assoc.*, 18 (1942), No. 4, pp. 211-215).—This paper summarizes further findings (*E. S. R.*, 62, p. 595) concerning the serial dental status of diabetic children receiving a controlled diet for a period of years. The evidence, in some cases including

accumulated data sufficient for valid statistical analyses, indicated that both enamel and dentinal caries had been avoided or lessened in occurrence and in extent concurrently with dietary control. The diets recommended were designed to meet optimal nutritional needs of these children through foods suited to their capacity for utilization, and included daily the following: 1 qt. milk; one or two eggs; two 4-oz. servings succulent, leafy, and root vegetables; two 4-oz. servings fruit, one of which was orange or raw fruit (tomato used as a substitute); one serving meat, fish, fowl, or liver; one teaspoonful cod-liver oil; and supplementary foods such as potatoes, starches, bread and other cereal products, sweets, and fats in amounts sufficient to complete the caloric requirement for full activity. Such a diet supplied about half of the calories in the form of highly protective foods. The nature of the supplementary foods was not considered important provided they were acceptable to the child and did not replace any of the more valuable specified ingredients. It is pointed out that improvement of dietaries of the whole child population is called for to establish optimal states of nutrition, and that the resulting anticipated improvement in health and performance would reflect itself in various ways, including avoidance of tooth decay.

**Effect of low calcium and vitamin D-deficient diet on bones and teeth of mature rats,** A. P. LUND and W. D. ARMSTRONG. (Univ. Minn.). (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 2, pp. 363-365).—Twenty male albino rats raised to an age of 11 mo. on a stock diet were transferred for 5 weeks to a control diet adequate in vitamin D and containing 0.462 percent calcium and 0.458 percent phosphorus; of these animals 10 were then transferred to the experimental diet deficient in vitamin D and containing 0.007 percent calcium and 0.450 percent phosphorus, and the experiment was continued for 220 days, during which time calcium and phosphorus balances were determined over 10-day periods. Calcium and phosphorus balances were positive for the control animals, while the experimental animals exhibited a severely negative calcium balance and a positive phosphorus balance. Dissection of the experimental animals showed the alveolar bone in which the molars were embedded to be soft and friable, the alveolar crest resorbed, and the teeth loosened as compared with normal calcified alveolar bone and firmly fixed molars of the controls. The average volume of the humeri of the experimental animals did not differ from the controls, but the average density was 10.8 percent less than the controls. Calcium and phosphorus contents as percentage of dry fat-free bones did not significantly differ, however, between the two groups of animals. These results indicated that determinations reported in terms of weight percentage do not serve to distinguish osteoporotic from normal bone, but that the degree of osteoporosis can be described in terms of ash weight or mineral content related to unit volume of bone. Calcium and phosphorus analyses of the dentin indicated that no mineral had been lost by the molar teeth of the experimental animals. The mineral composition of the incisor teeth was not significantly different between the two groups of animals.

**Human dental caries and topically applied fluorine.—A preliminary report,** V. D. CHEYNE (*Jour. Amer. Dent. Assoc.*, 29 (1942), No. 5, pp. 804-807).—An aqueous solution containing 500 p. p. m. of  $KF \cdot 2H_2O$  was topically applied, by a method preventing systemic ingestion, to the cleaned teeth of 27 children in the experimental group. These children and 19 of the control group ranged in age from about 4½ to 6 yr. All children received pre-phylaxis and examination upon initial and subsequent visits. The data obtained concerning the development and spread of carious lesions in the deciduous cuspid and molar teeth indicated that the application of fluorine in the manner described acted

more in suppressing carious activity in the existing lesions; the fluorine was effective, however, in preventing the development of new lesions.

**Observations on induced dental caries in rats, I, II** (*Jour. Dent. Res.*, 20 (1941), Nos. 2, pp. 97-105; 5, pp. 457-463, fig. 1).—Two papers are presented.

**I. Reduction by fluorides and iodoacetic acid.** F. J. McClure and F. A. Arnold, Jr.—The amount and degree of caries developing in young rats on a coarse corn meal caries-producing ration was observed in groups receiving, respectively, Galesburg, Ill., drinking water (E. S. R., 82, p. 713), Quincy, Ill., drinking water, water containing 2 p. p. m. F as NaF, and distilled water (control). The data obtained did not show any difference in the effects produced by these waters, but did point to a litter membership factor in rats with respect to their caries susceptibility. In other tests with rats on the caries-producing basal diet, it was found that the presence of 125 p. p. m. of F as NaF in the food or water and the presence of 200 p. p. m. of iodoacetic acid in the food, together with 20 p. p. m. of iodoacetic acid in the drinking water, significantly reduced the production of caries.

**II. The effect of subcutaneous injection of fluorides.** F. A. Arnold, Jr., and F. J. McClure.—Young rats placed at weaning on a noncaries-producing stock ration were transferred at somewhat more than 30 days of age to a caries-producing granulated corn meal ration. One group received drinking water containing 10 p. p. m. F as NaF, the control group received distilled water, and the injection group also received distilled water. Animals in the latter group received injections of 1 cc. of a solution of NaF equivalent to 0.5 mg. F every second day for the first 24 days and daily thereafter, making a total of 86 injections for each rat. Comparison of these groups with regard to their dental caries experiences indicated that the subcutaneous injection of NaF produced no significant reduction in induced dental caries. From observations on the injected rats it appeared that F, when introduced during the post-eruptive tooth period, exerted no systemic influence on induced rat caries. Analyses of the enamel and dentin of the incisor and erupted molar teeth of the rats showed that the F content of these tissues was increased by subcutaneous injection of the NaF and by feeding water containing 10 p. p. m. F. The higher F content of the molar teeth did not lead to increased resistance to caries.

**Observations on induced caries in rats.—III, Effect of fluoride on rat caries and on composition of rats' teeth.** F. J. McClure (*Jour. Nutr.*, 22 (1941), No. 4, pp. 391-398, figs. 2).—In continuation of this series of studies (noted above), control and test groups of rats aged from 23 to 25 days were placed on a corn meal caries-producing diet for 15 weeks, during which time the test rats received fluorine added to the drinking water or to the feed. A minimum of 10 p. p. m. F in the drinking water gave partial protection against occlusal caries, while about 80 percent protection resulted from both 50 and 100 p. p. m. F in the water and practically complete protection was afforded by 125 p. p. m. in the food. Since the observed action was not proportional to the fluoride deposited in the teeth, as determined by analysis of molar and incisor dentine and enamel, it is suggested that the caries-inhibiting action of the fluorine was by antienzymatic local action within the oral cavity. This view was substantiated by earlier findings that fluoride which did not reach the oral cavity, as when given by injection, was not caries inhibitory.

"The pooled molar teeth of groups of carious rats were not different from those of noncarious rats in content of ash, calcium, and phosphorus, and in fluorine which was deposited post eruptively. The post-eruptive addition of fluorine to rats' molar teeth occurred in relatively large quantities and is

regarded as occurring independent of oral enamel surface adsorption of fluoride. A significant effect of fluoride acquired after tooth eruption on induced rat caries was not evident."

**Fluorine acquired by mature dog's teeth**, F. J. McCLURE (*Science*, 95 (1942), No. 2462, p. 256).—Data are presented showing the increase in F content observed in the dentine and enamel of the teeth of a mature dog receiving fluorine in the food and drinking water for definite periods, each period terminating with the extraction of two or three comparable teeth. Each successive sample of dentine showed a decisive increase in F, but the enamel did not show a similarly consistent or equal percentage increase; the final concentration of F after a total of 559 days' exposure to the element was 0.072 percent in the dentine and 0.011 percent in the enamel. These results for the dog teeth, confirming similar results on young rats noted above, indicate that calcified dentine and enamel may undergo certain post-eruptive chemical modifications, and suggest that F retention may prove a useful tool in studying individual variation in dentine and enamel in relation to tooth age and susceptibility to dental caries.

**Prevention of dental caries by massive doses of vitamin D**, R. H. BRODSKY, B. SCHICK, and H. VOITLMER (*Amer. Jour. Diseases Children*, 62 (1941), No. 6, pp. 1183-1187, fig. 1).—In 101 children, hospitalized for close study for 1 yr. because of tuberculosis or contact with a patient with the disease, observations were made concerning the incidence of dental caries as affected by a single massive dose of vitamin D. The children were divided into three groups. The control group, receiving only the hospital diet devoid of cod-liver oil or any other additional source of vitamin D, developed 39 cavities, or 1.18 new cavities per child during the observation period; a second group, receiving in addition to the hospital diet 305,000 U. S. P. units of vitamin D and 2,455,000 U. S. P. units of vitamin A in a fish-liver oil concentrate, developed 13 cavities, or 0.39 cavity per child; while the third group, receiving 600,000 U. S. P. units of vitamin D in the form of crystalline vitamin D<sub>2</sub> in oil in addition to the hospital diet developed only 6 cavities, or 0.17 cavity per child. These results suggest that incidence of dental caries may be markedly decreased by the administration of a single massive dose of vitamin D. None of the children showed any toxic manifestation after the administration of such a dose.

**Serum phosphatase in experimental scurvy**, H. SHWACHMAN and B. S. GOULD (*Jour. Nutr.*, 23 (1942), No. 3, pp. 271-281, figs. 2).—The activity of alkaline serum phosphatase was determined during the development and subsequent course of scurvy in guinea pigs and during treatment with varying amounts of ascorbic acid. Similar tests were made of serum acid phosphatase. During the feeding of a scurvy-producing diet, there was an immediate and continued decline to very low levels in the alkaline serum phosphatase, followed by alternate increases and decreases during periods of adding and omitting ascorbic acid. There was no apparent change in the serum acid phosphatase or serum inorganic phosphate. Rabbits, which are able to synthesize ascorbic acid, showed no decline in serum alkaline phosphatase when fed a scurvy-producing diet. No activation of low serum phosphatase by ascorbic acid occurred in vitro. The in vivo effect is thought to be due to an increase in enzyme production during recovery from scurvy.

**The decomposition of pectin and galacturonic acid by intestinal bacteria**, S. C. WERCH, R. W. JUNG, A. A. DAY, T. E. FRIEDEMANN, and A. C. IVY (*Jour. Infect. Diseases*, 70 (1942), No. 3, pp. 231-242).—The conclusion made earlier (E. S. R., 87, p. 142) that the decomposition of pectin in the colon must be due to micro-organisms is confirmed in this paper, which reports work on the

isolation and identification of the bacteria responsible for the enzymes involved, the products of decomposition, and the various pectinases used.

Suspensions of dog feces representing the residue of a general diet to which pectin had been added proved a less satisfactory medium for the isolation of pectin-decomposing bacteria than feces from a diet of pectin alone. A number of organisms capable of decomposing pectin were isolated, the more active of which were identified as belonging to the *Aerobacillus*, *Lactobacillus*, *Micrococcus*, and *Enterococcus* groups. Berkefeld filtrates of the organisms, as well as of feces suspensions, contained a heat-labile enzymelike substance. Certain organisms produced a pectinase-like or liquefying organism, others the same or a pectase-like coagulating enzyme. The filtrates of feces suspensions produced only liquefaction. An *Aerobacillus* strain and a mixture of *Micrococcus* and *Enterococcus* decomposed galacturonic acid, with formic and acetic acids as the chief end products. These were also the chief end points of the bacterial decomposition with, in addition, a small amount of galacturonic acid.

**The graying of hair**, A. HEDLICKA (*Jour. Amer. Med. Assoc.*, 118 (1942), No. 11, p. 918).—In this editorial it is pointed out (1) that the hair may be considered as a form of an organ serving, through its pigment, as a fairly important means of eliminating byproducts of metabolism, notably melanin, and (2) that the ordinary graying of hair signifies that less and less melanin is being formed and, therefore, less and less is present in the hair. While starvation or prolonged severe nervous stresses may conceivably diminish or stop production and hence the elimination of melanin, yet this effect would cease with restoration of normal conditions. "If the hair and its 'pigment' are viewed in this manner and the normal graying is regarded as a gradual decline in the production of melanin, it is difficult to see how any vitamin or other substance given to the subject could restore former conditions. Something of this nature could conceivably be possible for a time in the early stages of the process but would steadily grow more difficult with time until it became impossible. It would be in vain, it would appear, to expect now or in the future more from drugs or other substances than a possible delay of graying, or a partial halting of the process, with perhaps moderate restoration for a time, during the earlier stages of the graying period."

**The immediate effect of cigarette smoking upon basal metabolic rates of university men and women**, V. R. GODDARD and J. G. VOSS. (Univ. Calif.). (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 6, pp. 787-791).—The metabolism tests were conducted with standard precautions and procedures on college men and women accustomed to smoking either habitually or occasionally and selected at random from students apparently in good physical condition. The results presented show that the apparent basal metabolic rate determined approximately  $\frac{1}{2}$  hr. after smoking may be either above or below the control test taken prior to smoking, and that the deviation is by no means constant. A rise in the pulse rate, respiration rate, and body temperature following smoking was generally observed. The sex of the subject apparently did not influence the energy output following smoking.

## TEXTILES AND CLOTHING

**Microscopic structure of flax and related bast fibers**, C. W. HOCK (*Jour. Res. Natl. Bur. Standards [U. S.]*, 29 (1942), No. 1, pp. 41-50, figs. 12; also in *Amer. Dyestuff Rptr.*, 31 (1942), No. 14, pp. 334-342, figs. 12; abs. in *Textile Res.*, 12 (1942), No. 9, pp. 26-29, figs. 4).—Two varieties of *Linum usitatissimum* were used for most of the experiments, and most of the work was limited to fibers

that had received as few treatments as possible. Other samples of flax, hemp, ramie, and jute, including some commercially retted fibers, were used for comparison, however. In retting, the tissues of the flax were softened, permitting separation of the bast fibers contained in the outer cortex of the stem from the central woody core. The cambium layer, lying between these two regions, was softened first, followed later by softening of the thin-walled cells in the cortex. The flax fibers, as well as those obtained from hemp, jute, and ramie, were in the form of long filaments, each of which was made up of cells. In this respect they differed from cotton fibers which are single plant cells. The flax cell was observed to have a primary and a secondary wall. The former constituted the surface of each cell and consisted largely of wax and other material, presumably of a pectic nature. The secondary wall of cellulosic nature comprised the bulk of the fiber.

The experimental procedures used in studying the microscopic structure of the flax fiber included treatment of the raw and dewaxed fibers with cuprammonium reagent. In suitable dilutions this reagent did not completely dissolve the cellulose, but instead caused the fibers to swell considerably, thereby revealing many details of structure. Thus, the secondary wall was observed to be made up of innumerable cellulose fibrils, the outermost layer of which wound in one direction, whereas the majority of the fibrils beneath this layer wound in the opposite direction. These fibrils were grouped to give the wall a lamellar pattern. There was a greater number of these layers in the walls of the cells at the base of the stem than in the cells from the growing tip. There was also a corresponding increase in thickness of the wall from the tip of the stem where the cells originated to the base where they matured. All the bast fibers had essentially similar structures. Flax and ramie, however, differed from hemp and jute in the directions of orientation of the fibrils, and this accounted for some of the differences in the physical properties of the two groups.

**Review on the structure of cellulose fibers, W. MARQUETTE** (*Rayon Textile Mo.*, 23 (1942), No. 9, pp. 62-63).—This review deals with the controversial discussion concerning the physical organization of cellulose, as based upon the work of Farr (E. S. R., 87, p. 318) on the one hand, and of Hock and Harris (E. S. R., 85, p. 282) on the other, with independent supporting studies by various other investigators.

**Elasticity of wool as related to its chemical structure, M. HARRIS, L. R. MIZELL, and L. FOURET** (*Jour. Res. Natl. Bur. Standards [U. S.]*, 29 (1942), No. 1, pp. 73-86, figs. 6; also in *Amer. Dyestuff Rptr.*, 31 (1942), No. 16, pp. 376-380, 392-394, figs. 6; *Indus. and Engin. Chem.*, 34 (1942), No. 7, pp. 833-838, figs. 6).—Observations were made on the elastic behavior of wool and of chemically modified wools in which the mode of linkage of the sulfur was altered without visibly affecting the fiber structure (E. S. R., 87, p. 157). The observed "long-range" elasticity of the wool is explained as due to the particular structure of the wool protein molecules, these being long flexible chains free to assume various shapes and, unlike those of other textile fibers, characterized by the presence of covalent disulfide cross links between the main molecular chains. These short cross links at intervals produce a three-dimensional or network structure, so that when wool is stretched or folded the chains, although they slide past one another, do not slide permanently out of position; rather, tensions are set up which cause the fiber to return to its original shape after the removal of the external force. In this respect wool is analogous to rubber in which cross chains are presumably formed during vulcanization. Thus the stress-strain, solubility, and swelling characteristics are greatly influenced by the extent of

the cross linking in the two materials. Rupture of the chemically modified wool decreased the strength of the fiber without necessarily affecting the elastic recovery. Rebuilding the covalent linkages largely restored the original properties of the fiber.

**Volumetric determination of moisture in cotton textiles, J. F. KEATING and W. M. SCOTT. (U. S. D. A.). (Amer. Dyestuff Rptr., 31 (1942), No. 13, pp. P308-P310, fig. 1).—**The determination of water in mixtures by titration with the Karl Fischer reagent (containing iodine, sulfur dioxide, and pyridine dissolved in methanol) was successfully applied in the determination of moisture regain in cotton textiles by extraction of the fabric with cold methanol and subsequent titration of the water in the extract with the reagent. The titration procedure resulted in considerable saving of time, and the results obtained were more accurate than those obtained by the standard procedure of oven drying at 105°–110° C.

**Rayon in first six months of 1942, W. C. APPLETON (Rayon Textile Mo., 23 (1942), No. 7, p. 36).—**Rayon, the production of which in the first 6 mo. of 1942 showed an increase of about 13 percent over that in the corresponding period in 1941, is finding increased use for military purposes. In addition to the established uses for linings, Army chevrons and insignia, self-sealing gasoline tanks, and tire cord, it has been adopted or employed on an increased scale for several types of parachutes, parachute shroud cords and tapes, aerial tow targets, electric wire covering, and Army sleeping bag linings. Spun rayons have been adopted for uniform interlining materials, heavy curtains for Navy ships, and for lint-free wiping cloths used by the Army and Navy for cleaning binoculars, range finders, and other types of high grade optical equipment. Rayon is also finding increased use in yarn and fabrics used by the Red Cross and for civilian purposes, increased use in the hosiery industry, and in the manufacture of rayon and wool blended fabrics.

**Plastic-coated rayon yarns, H. R. MAUERSBERGER (Rayon Textile Mo., 23 (1942), No. 8, p. 56, fig. 1).—**This paper notes briefly the development, from French patents acquired in this country, of synthetic yarns known as "Plexon" yarns, "Cota-cord," and "Cota-tape." These are plastic-coated yarns, chiefly rayon filament yarns, of great flexibility and strength. The 17 different formulas now available allow for a wide latitude in finish and color (resistant to washing and light), and the thickness of the coatings, which may be single or multiple, can be controlled to 0.001 in. The yarns are not sticky, will not crack, are grease- and waterproof, may be flexible or rigid, and may be woven, knitted, braided, crocheted, and knotted on ordinary equipment now in common use. Applications seem to be unlimited, and at present table mats, millinery, hat bands, Chantilly lace, wide fabrics for draperies, shoe fabrics, and mesh fabrics for use as a substitute for screening are being made from Plexon.

**Physical methods for evaluating the hand of fabrics and for determining the effects of certain textile finishing processes, E. C. DREBY (Amer. Dyestuff Rptr., 31 (1942), No. 21, pp. P497-P504, figs. 7).—**"Of the eight physical properties of a fabric appreciated by the sense of touch, three proved to be the most important characteristics contributing to the 'hand' or 'feel' of soft-finished fabrics. These are flexibility, surface friction, and compressibility. The Planoflex [E. S. R., 86, p. 568], Friction-Meter, and Compression-Meter were developed for the evaluation of these respective properties. It was shown that these three properties were associated with the components of hand termed 'pliability,' 'smoothness,' and 'fullness,' and that they permitted the quantitative specification of hand. The Planoflex, Friction-Meter, and Compression-Meter are sensitive to small differences in finish, and in addition to their use in evaluating hand they

can be used to evaluate the effectiveness of different finishing agents, to control finishing processes, and to evaluate the effects of other factors affecting the hand of fabrics. The instruments are rugged and practical, making them suitable for routine textile testing. They are satisfactory for the measurement of all soft-finished woven fabrics."

**Note on flexural fatigue of textiles**, H. F. SCHIEFER and P. M. BOYLAND (*Jour. Res. Natl. Bur. Standards [U. S.]*, 29 (1942), No. 1, pp. 69-71, pls. 3).—The percentage decrease in breaking strength and elongation was observed in fabrics flexed under tension at the rate of 200 double folds per minute for a total of from 1,000 to 50,000 double folds. Microscopic observation of the flexed specimens indicated that the position of the failures of the fibers was in alternate yarns. This effect was entirely attributable to the differences in stress and strain arising from the fabric structure, the bending stress due to folding a given yarn increasing with increase in curvature of the fold. The percentage decrease in elongation and breaking strength depended upon the number of double folds and the kind of fiber. Fibers made from viscose rayon, Nylon, and cotton showed no decrease in elongation and breaking strength as compared with large decreases in fabrics made from acetate rayon, fortisan, and silk. This difference was not due to change in weave or fabric structure, but to structural differences in the yarns and in the fibers in the yarn. Thus, the short cotton fibers in the yarn were freer to move relative to one another when the fabric was flexed, and the fibers, therefore, were strained less when the yarn was bent. This resulted in an increase in folding endurance. The results of the study indicate that the ability of a textile fabric to withstand repeated flexing depends upon the structure of the fabric, the position and structure of the yarn in the fabric, and the kind of fiber from which the fabric is made.

**Some factors affecting life of fabrics are explained by research on flexural fatigue**, H. F. SCHIEFER and P. M. BOYLAND (*Textile Res.*, 12 (1942), No. 11, pp. 2-7, figs. 3).—Essentially noted above.

**The sanitization of textiles: Investigation of self-antiseptic and self-sterilizing effects of treatment**, L. H. JAMES. (Univ. Md.). (*Textile World*, 92 (1942), No. 6, pp. 86-87, figs. 3).—Tests, noted briefly, are interpreted as indicating that the solutions of commercial sanitizing materials used effectively inhibited growth, and even sterilized (reduced the bacterial content), sanitized materials inoculated with test organisms.

**A study of towels and toweling for consumer use**, N. G. BENNETT and P. E. KEENEY (*Missouri Sta. Bul.* 452 (1942), pp. 32).—As guides for judging the quality of terry cloth towels, tea towels, and toweling materials, obtained in various qualities and at various prices at representative stores in Missouri, laboratory tests were made to determine weight, tensile strength, thread count, colorfastness, and water absorption capacity. These findings as a guide to quality were compared with the guidance afforded the consumer by the usual methods of inspection, reliance upon trade-marks and brand names, past experience, and price. In the case of terry towels, in which strength and hence durability depended upon the number of yarns to the inch in the background of the towel and absorbability upon the weight, which involved length and closeness of pile, the usual buying guides were inadequate or inefficient. Price was no indication of quality, towels 22 by 24 in. in size, for example, costing from 18 ct. to \$1.50; trade-marks and brands served only to identify the manufacturer; and inspection served mainly to distinguish between the highest and the lowest grade, it being very difficult to distinguish between similar grades. While informative labels would be of advantage to the consumer, there were but very few manufacturers

who made any attempt to label their goods. The majority of terry towels tested were fast to both sunlight and laundering.

In the case of the tea towels and toweling materials, made of cotton, linen, or mixtures of these or rayon mixtures, thread count was no reliable indication of durability, due to the variation in the size of the yarns. Towels and toweling of each fiber content varied considerably in strength. Tensile strength depended upon a combination of the fiber content of the yarns, the number of yarns to the inch, and the size and amount of twist in these yarns. Price was no indication of durability of construction or strength, for all towels and toweling materials, when arranged according to price, showed wide ranges in both thread count and tensile strength. About one-fourth of the materials tested were not fast to light, but most of them were fast to laundering. Towels of cotton absorbed the greatest amount of water, but those of linen absorbed moisture more rapidly and dried much faster than the others. It made very little difference in serviceability whether the towels were purchased ready-made or as the toweling; the latter showed a greater tendency to be colorfast, but was slightly less absorbent in some cases. Flour sacking, which ranked above the average in all tests except those for tensile strength and colorfastness, proved to be a very satisfactory type of towel for the money expended.

### MISCELLANEOUS

**Research and farming: Sixty-fourth Annual Report of [North Carolina Station, 1941], L. D. BAYER (*North Carolina Sta. Rpt. 1941, pp. 83, figs. 33*).<sup>1</sup>**

<sup>1</sup> The experimental work not previously referred to is for the most part noted elsewhere in this issue.

## NOTES

---

**Georgia Coastal Plain Station.**—G. H. King has been appointed director.

**Illinois University and Station.**—Dr. James M. Brannon, assistant professor and assistant chief in dairy bacteriology since 1922, died January 21 at the age of 60 years. A native of Indiana, Dr. Brannon was graduated from the University of North Dakota in 1907, subsequently receiving the M. A. degree from the University of Wisconsin in 1914 and the Ph. D. degree from Cornell University in 1920. He had taught botany, zoology, and plant physiology in the Universities of North Dakota, Wisconsin, and Cornell and had served with the North Dakota geological and biological surveys.

**Indiana Station.**—Dr. H. Rex Thomas, associate pathologist and engaged on problems connected with tomato diseases, is now in military service. Dr. Forrest W. Quackenbush has been appointed head of the department of agricultural chemistry. Dr. D. M. Doty, acting head of this department since the resignation of Dr. H. R. Kraybill in 1942, has been appointed assistant chief.

**Maine Station.**—Dr. D. S. Fink has resigned as associate agronomist, effective February 28, to accept a position in Cornell University.

**Michigan College and Station.**—Eben Mumford, head of the department of sociology from 1924 until his retirement in 1938, died October 17, 1942. He was a graduate of Buchtell College and received the Ph. D. degree for work in sociology at the University of Chicago. He came to Michigan in 1912, serving on its extension staff for 12 years.

**II. H. Musselman**, head of the department of agricultural engineering, has retired.

**Nebraska University and Station.**—Following the induction into military service of the county agent of Cherry County, E. M. Brouse has been put in charge of the extension program in that county but will also continue as superintendent of the substation at Valentine. Dr. Arthur W. Peterson, assistant professor and assistant in rural economics, has resigned to become associate agricultural economist in the Washington Station vice Alden E. Orr, resigned. Glenn Klingman, instructor and assistant in agronomy, has joined the armed forces.

**New Mexico College and Station.**—Marvin Koger has been appointed assistant animal husbandman and instructor in animal husbandry.

**Utah College and Station.**—Dr. Charles W. Riggs has been appointed to the veterinary staff vice Dr. Wayne Binns, who has been granted military leave.

**Washington College and Station.**—Dr. J. G. Harrar, plant pathologist and head of the division of plant pathology, has accepted a position with the Rockefeller Foundation as director of a new research and demonstration agency, with headquarters in México. D. F. Herman Fallscheer, assistant chemist at the Tree Fruit Branch Station, has resigned to accept a position with the U. S. Food and Drug Administration. Dr. J. C. Knott, associate dairy husbandman, has been appointed director of the college agricultural extension service vice F. E. Balmer and has been succeeded by Dr. A. A. Spielman, field agent in dairying at the University of Kentucky. Carl N. Berryman has been appointed assistant in agricultural economics vice W. W. Rufener, resigned to become asso-

ciate agricultural economist in the U. S. D. A. Agricultural Marketing Administration.

**Wyoming University and Station.**—John F. Cykler, instructor and assistant in agricultural engineering, has been granted leave of absence for naval service.

**Inter-American Institute of Agricultural Sciences.**—According to a recent article in *Agriculture in the Americas*, a site for this institute has been selected on the outskirts of Turrialba, a town in the interior of Costa Rica approximately midway between the national capital of San José and the principal port of Puerto Limón. The tract chosen for the main buildings and campus consists of 1,235 acres adjoining the U. S. D. A. Costa Rica Rubber Experiment Station. Most of the land has an elevation of about 2,000 ft., but wet lowland areas are included. The soils of the region are volcanic, temperatures average in the middle 70's, rainfall amounts to around 110 in. a year, and the humidity is high. The site is regarded as suitable for experimental cultivation of practically all tropical crops, for experimental work on livestock and dairying under tropical conditions, for study of tropical reforestation and erosion control problems, and for investigation of drainage practices. Nearby areas are well suited for the development of tropical crops not adapted to the lowlands.

The institute is to be managed by a corporation, directors of which will be the members of the Pan-American Union Governing Board, which consists of the United States Secretary of State and the diplomatic representatives in Washington of all the Latin-American republics. Projects will be recommended by a technical advisory committee composed of a member from each of the countries participating. At the outset, the organization will be financed largely by the United States, but it is expected that the other countries will join in the financing later under a convention to be signed.

The institute is conceived as a combination school of agriculture and agricultural research center, the facilities of which will be used by all of the American republics. Its objectives, as generally agreed upon by agricultural leaders of the hemisphere, are to provide a place for research on tropical agriculture under favorable conditions, to furnish facilities for training scientific personnel grounded in tropical agricultural problems, to develop mutual understanding among agricultural students of the Americas, to serve as a center for cooperative research projects, and to strengthen cultural relations among the American republics.

Plans for the institute contemplate utilization of research facilities offered by the governments of several Latin American republics as well as those of Costa Rica. Among the organizations whose facilities have been offered are the experiment stations of Puerto de Diaz (in Salta) and Loreto (in Misiones), Argentina, situated in the subtropical region of the country; the station located at Chulumani near La Paz and the farms of Trinidad and of Palermo in Santa Cruz, Bolivia; the Agronomical Institute in Belém State of Pará, Brazil; the experiment station at Palmira, Colombia; the experimental fields situated in the region between the capital and Santa Ana in the large region of Tapachula, State of Chiapas, Mexico; the experiment station at Tingo María, Peru; the Agricultural Experiment Station at Santiago de las Vegas, near Habana, Cuba; and the Institute of Tropical Agriculture at Mayaguez, Puerto Rico.

As previously announced the director of the institute is Dr. Earl N. Bressman, who is expected to operate from Washington, D. C., with a small administrative staff. José L. Colom, chief of the division of agricultural cooperation of the Pan American Union, has been appointed secretary of the organization; Rex A. Pixley, business manager of the institute, and Robert A. Nichols, agriculturist in charge of field operations.

## RECENT WORK IN AGRICULTURAL SCIENCE

---

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

**Natural and synthetic high polymers:** A textbook and reference book for chemists and biologists, K. H. MEYER, trans. by L. E. R. PICKEN (*New York*): Interscience Pubs. Inc., 1942, pp. XVIII+690, flgs. [182].—"During the last 10 yr. . . a branch of chemistry [that of the more highly polymerized natural organic compounds] has been developing which is destined to provide biology with much more than methods. . . ."

"The common meeting ground of chemists and biologists in high-polymer chemistry is that of morphology. Since the day when, as a result of the development of X-ray analysis, chemical formulas ceased to be symbols on paper and became models in three dimensions, the chemist has become more and more accustomed to think in terms of what may be called morphological chemistry. To the biologist, who observes that both shapes and properties of cells and cell components reflect their molecular organization, it seems likely that morphological chemistry may prove to be the chemistry of morphology. It is for him now to consider biological structure and organization in their high-polymer guise and to formulate for himself the questions which high-polymer chemistry will go far toward answering."

A short introduction presents a definition and classification of high polymers and discusses homologous polymeric series and mixtures of polymeric homologues, molecule and molecular weight, and the morphological approach to the chemistry of high polymers. Section A, the study of high polymers, takes up investigation in solution and the determination of molecular shape and arrangement in the solid state. Section B deals with inorganic high polymers; section C with high-polymeric hydrocarbons and their derivatives; section D treats of polymeric ethers, esters, sulfides, etc.; section E of cellulose and its derivatives; section F of substances related to or associated with cellulose; section G of starch and related carbohydrates; section H of the proteins; section I of the properties of high polymers in solution; section K of films, foils, and membranes; and section L of direct optical methods for the study of submicroscopic fine-structure (ultraviolet microscopy and the electron microscope), micellar theory and chain-molecule theory, and indirect methods for determining the molecular fine-structure of living substance. A table for finding the specific viscosity  $K$  and the limiting viscosity of cellulose, cellulose esters and ethers, and rubber from the relative viscosity is included as an appendix. An author index and a subject index are added.

**Industrial microbiology**, S. C. PRESCOTT and C. G. DUNN (*New York and London: McGraw-Hill Book Co., 1940, pp. X+541, figs. 60*).—This work is intended as a textbook for advanced students or for reference use. The assumption is made, therefore, that the student or reader will already have had somewhat extensive training in biology and general bacteriology and at least the fundamentals of organic chemistry and biochemistry. The field of applications covered is purely industrial, discussion of the manufacture of sera, vaccines, and other therapeutic agents being omitted, as is also reference to the production of cultures of nitrogen-fixing bacteria and of butter- and cream-ripening organisms. Special attention has been given (1) to a broad treatment of those large-scale fermentations in which the end products are of themselves industrially or potentially important, and (2) to consideration of others that are of special significance because of the modifications of the quality of substrate materials that they produce, as in some aspects of food technology. Following a single chapter of introduction, the book consists of four parts of the titles and contents respectively indicated. Part 1, the yeasts—a study of their activities and industrial applications, deals with the yeasts; the production of industrial alcohol by fermentation; facts and theories concerning the mechanism of the ethyl alcohol fermentation; brewing; wine; the distilling industries; yeast—its manufacture, vitamins, and uses; the glycerol fermentation; and fat production by yeasts and yeastlike micro-organisms. Part 2, the bacteria—a study of their activities and industrial applications, consists of chapters on the bacteria, the acetone-butanol fermentation, the acetone-ethanol fermentation, the butyl alcohol-isopropyl alcohol fermentation, the acetic acid bacteria and some of their biochemical activities, the production of lactic acid by fermentation, sauerkraut, pickles, silage, some lactic acid bacteria and some fermented milk products, cheese, the propionic acid fermentation, and some minor fermentations with industrial implications. Part 3, the molds—a study of their activities and industrial applications, takes up the molds, the citric acid fermentation, the gluconic acid fermentation, the production of lactic acid by molds, the gallic acid fermentation, the kojic acid fermentation, the fumaric acid fermentation, mannitol production by molds, mold enzyme preparations—uses and products, the production of fat by molds, and some minor chemical activities of the lower fungi. Part 4, specialized activities of the molds, yeasts, and bacteria, is made up of two chapters—textile microbiology and the microbiology of wood. Two appendixes—A, detergency, disinfection, and sterilization, and B, the treatment and disposal of industrial microbiological wastes—and a subject index conclude the volume.

**Text-book of comparative histology**, E. C. COLE (*Philadelphia: Blakiston Co., [1941], pp. VII+396, figs. 297*).—The author finds the comparative viewpoint, though of proved value in gross anatomy, to have been somewhat neglected in the study of tissues. A student handbook rather than a reference book is intended. Photomicrographs have been freely used so that the student may become familiar with tissues as they appear in actual histological preparations. A short chapter on the nature, use, and care of the microscope is included. The treatment of the microscope is necessarily incomplete, but the student is referred to *The Use of the Microscope*, by Belling (E. S. R., 67, p. 201), to other textbooks, and to work ancillary to that of Belling (E. S. R., 74, p. 767). The processes of fixing, washing, denhydrating, imbedding and cutting, staining, and mounting of sections, as well as temporary mount procedures, insofar as they apply to animal histology, are dealt with in working detail, and specific examples for practice work are described. The four sections of the book are made up of the chapters respectively noted: Introductory section—the problems of histology, the nature of cells, and the origin of tissues; the structure and functions of

tissues—epithelial tissues, vascular tissues, connective tissues, supporting tissues, contractile tissues, and nerve tissue; organs as tissue complexes—the blood-vascular system, the lymphatic system, the integument, the digestive system, the respiratory system, the excretory system, the reproductive system, the endocrine system, the nervous system, and the sense organs; and instruments and methods—the use and care of the microscope, methods of recording data, and histological technic.

[Chemical investigations by the Georgia Station] (*Georgia Sta. Rpt. 1942*, pp. 66-68, 76-77, 86-89).—Data are given on the protein and mineral content of lespedeza and Bermuda grass, together with work on peanut proteins, utilization of peanuts, sorghum sirup, and the effect of handling peanuts in the field on the quality of the nuts and oil (coop. Ga. Coastal Plain Expt. Sta.).

[Chemical investigations by the Kansas Station] (*Kansas Sta. Bienn. Rpt. 1941-42*, pp. 27, 28-30, 34-35).—Subjects studied included chemical factors influencing the quality of wheat and flour, worked on by E. G. Bayfield and A. L. Clapp; tempering factors that affect the quantity and quality of wheat flour, by R. O. Pence and J. E. Anderson; factors which influence the colloidal properties of dough, by C. O. Swanson and E. B. Working; the influence of some factors affecting the physical properties of wheat, by Swanson; conditioning requirements of wheat and their influence upon milling and baking, by Pence and W. F. Keller; the effect of  $\text{ICl}_3$ , ethylene gas, and  $\text{Cl}$  on the quality of Kansas wheat, by Bayfield et al.; and industrial utilization of sorghum grains, by H. N. Barham and J. W. Greene.

[Chemical investigations by the Oregon Station] (*Oregon Sta. Bul. 401 (1941)*, pp. 38, 71-72).—Factors affecting the stability of erythrosine dye in cherry tissue; razor clam qualities as affected by canning, freezing, and storage procedures; and salmon cheek quality as affected by freezing and storage are reported upon briefly.

[Chemical investigations by the Puerto Rico Station] (*Puerto Rico Sta. Rpt. 1941*, pp. 5-7, 7-9, 10-11, 23).—The processing of vanilla beans, by A. G. Kevorkian and F. E. Arana, and the chemical changes involved in flavor development, by A. K. Balls and Arana, are reported upon, together with agronomic and processing studies with essential oils from lemon grass and coffee flowers, by A. R. Villamil and N. G. Arrillaga, and chemical studies in the distillation of bay oil, by Arrillaga and M. A. Jones; drug plant chemistry of *Cinchona*, digitalis, and jimsonweed, by H. T. Love; and analyses of lemon-grass distillation residues, by J. O. Carrero.

The chemistry and toxicity of selenium compounds, with special reference to the selenium problem, E. P. PAINTER. (N. Dak. Expt. Sta. and Univ. Minn.). (*Chem. Rev.*, 28 (1941), No. 2, pp. 179-213).—Under the head of the selenium problem in agriculture, the author briefly traces the history of observed selenium poisoning from the observations of Marco Polo in China to the present time and discusses the toxicity of various selenium compounds both as they occur in nature and as feed or injected in laboratory experiments, selenium in soils and in plants, and the relation between selenium and sulfur in plants. The second main division of the review is devoted to methods for the determination of selenium, the third to organic compounds of selenium, and the fourth to the properties of selenium in plants and their relation to known compounds of selenium and of sulfur.

The mucilage from Indian wheat, *Plantago fastigiata*, E. ANDERSON, L. A. GILLETTE, and M. G. SEELEY. (Univ. Ariz.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 569-574).—A mucilage isolated from the seed of Indianwheat, *P. fastigiata*, in a yield of approximately 19 percent of the weight of the seed was

found to be a mixture of acids varying in composition approximately from that of 8 to that of 17 pentosan molecules, combined with 1 molecule of *d*-galacturonic acid. The mixture consisted of salts of *d*-galacturonic acid, combined by a glycosidic union from its aldehyde group with a chain of a few molecules of *l*-arabinose, this being attached to a longer chain of molecules of *d*-xylose, and the *d*-xylose apparently attached to a small proportion of some material which remains as an insoluble precipitate when the mucilage is hydrolyzed. The *P. fastigiata* mucilage was found very similar in composition and properties to the mucilage isolated from *P. psyllium*.

The chemical nature of actinomycin, an antimicrobial substance produced by *Actinomyces antibioticus*, S. A. WAKSMAN and M. TISLER. (N. J. Expt. Stas. et al.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 519-528, figs. 3).—A red pigment, designated as actinomycin A, has been isolated in a pure crystalline form from a soil organism, *A. antibioticus*. Out of 250 strains of actinomycetes tested, no other organism appeared to produce this pigment. Actinomycin was found to contain 59 percent carbon, 6.8 hydrogen, 13.35 nitrogen, and 20.8 percent oxygen. It appeared to be a polycyclic nitrogen compound, was optically active, had a molecular weight of about 800, exhibited characteristic absorption both in the visible and ultraviolet regions, and seemed to have a reversible oxidation-reduction system, apparently of a quinone type. Actinomycin was found an active bacteriostatic and bactericidal (as well as fungistatic and fungicidal) agent, the degree of activity varying with the nature of the organism. It was active in concentrations of 1:100,000,000 against certain gram-positive bacteria, and was found highly toxic to animals.

The threonine, serine, cystine, and methionine content of peanut proteins, W. L. BROWN. (Ga. Expt. Sta.) (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 299-301).—Arachin and conarachin were found to contain, respectively, 2.56 and 2.02 percent of threonine, 5.20 and 4.99 of serine, 1.51 and 2.92 of cystine, and 0.67 and 2.12 percent of methionine.

Does hydroxyglutamic acid occur in milk proteins? B. H. NICOLET and L. A. SHINN. (U. S. D. A.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 139-146).—Using a reaction with a periodate in alkaline solutions (15 cc. of saturated potassium carbonate solution, from 1 to 2 cc. of 0.5-M periodic acid, and an aliquot of the protein hydrolyzate equivalent to from 100 to 200 mg. of the protein in not more than 5 cc.), by which  $\alpha$ -amino- $\beta$ -hydroxy acids are broken up rapidly and quantitatively to yield two aldehydes and ammonia, the authors obtained evidence strongly indicating the entire absence of hydroxyglutamic acids from the hydrolyzates of casein, lactalbumin, and lactoglobulin. The ammonia evolved in this reaction was all accounted for as threonine and serine in molecular ratios almost exactly integral. In casein this threonine : serine molecular ratio was very close to 3:5 (0.598), in lactalbumin 1:1 (0.973), and lactoglobulin 4:3 (1.335). To show that hydroxyglutamic acid would not be entirely destroyed in protein hydrolysis, if originally present, samples of the acid were added to casein before hydrolysis, and 56 and 70 percent, respectively, could be recovered from two hydrolyses. Other evidence supporting the authors' contention that either no hydroxyglutamic acid or very little is present in the milk proteins was also obtained.

The modification of cupric chloride crystallization patterns by traces of proteins, D. L. and C. T. MORRIS (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 515-520, pl. 1).—Minute quantities of proteins can greatly modify the cupric chloride crystallization patterns produced by polysaccharides and similar substances. This modification is apparently not due entirely to surface tension

effects. The protein effect seems to depend upon the total amount of protein present rather than on the proportion of protein to polysaccharide.

The specificity of the pattern so far described appears to be due to the polysaccharides, whereas the action of the proteins is entirely nonspecific.

**The synthesis of *l*-S-( $\beta$ -amino- $\beta$ -carboxyethyl)homocysteine and the replacement by it of cystine in the diet**, V. DU VIGNEAUD, G. B. BROWN, and J. P. CHANDLER. (Cornell Univ.). (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 59-64, figs. 2).—The new amino acid was synthesized by treating *l*-homocysteine with *l*- $\alpha$ -amino- $\beta$ -chloropropionic acid hydrochloride under conditions described in working detail. N,N'-Dibenzoyl-*l*-S-( $\beta$ -amino- $\beta$ -carboxyethyl) homocysteine was also prepared.

It was shown that the amino-acid-thio ether can serve in lieu of cystine in the diet for the support of growth of animals. The possible significance of this finding to the question of the mechanism of the conversion of methionine and homocysteine to cysteine is discussed.

**The formation of lanthionine on treatment of insulin with dilute alkali**, V. DU VIGNEAUD, G. B. BROWN, and R. W. BONSNES. (Cornell Univ.). (*Jour. Biol. Chem.* 141 (1941), No. 2, pp. 707-708).—After destruction of much of the cystine either by sodium carbonate (2-percent solution) or by sodium hydroxide solution (N/30), samples of insulin yielded, by acid hydrolysis, about 1 percent of the weight of the insulin as lanthionine. This yield, containing about 5.5 percent of the total sulfur, is, with reference to percentage of the total sulfur content, similar to that obtained from wool.

**The preparation of histidine by means of 3,4-dichlorobenzenesulfonic acid**, H. B. VICKERY. (Conn. [New Haven] Expt. Sta.). (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 77-87).—The author showed that when a liberal excess of 3,4-dichlorobenzenesulfonic acid is added to a decolorized hydrochloric acid hydrolyzate of crude hemoglobin at pH 1.2 to 1.6, histidine slowly separates in the cold as the relatively insoluble di-3,4-dichlorobenzenesulfonate. The histidine salt is at times accompanied by a considerable quantity of impure leucine mono-3,4-dichlorobenzenesulfonate, but the mixture can readily be separated by recrystallizing and taking advantage of the marked capacity of the impure leucine salt to form a supersaturated solution. Most of this can be removed from the crystals of histidine salt by decantation under the correct conditions; the histidine salt is then readily purified by recrystallization. Histidine is recovered in satisfactorily pure form, either as free base or as the monohydrochloride, after removal of the sulfonic acid as its insoluble barium salt. The yields depend upon the purity of the starting material with respect to its content of hemoglobin; from fairly pure preparations of red blood cells, the equivalent of over 6 percent of histidine has been obtained.

**Aromatic sulfonic acids as reagents for amino acids: The preparation of *l*-serine, *l*-alanine, *l*-phenylalanine, and *l*-leucine from protein hydrolyzates**, W. H. STEIN, S. MOORE, G. STAMM, C.-Y. CHOU, and M. BERGMAN (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 121-129).—On the basis of the solubility products of their amino acid salts, several sulfonic acids derived from diphenylamine, anthraquinone, and azobenzene were found to be of potential value for the isolation, purification, and determination of amino acids. The utilization of sulfonic acids for the preparation of amino acids is exemplified by procedures for the isolation of *l*-phenylalanine and *l*-leucine from hydrolyzates of hemoglobin and of *l*-serine and *l*-alanine from hydrolyzates of silk fibroin.

**Threonine deficiency in hydrolyzates of zein prepared by autoclaving**, R. BORCHERS, J. R. TOTTER, and C. P. BERG (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 697-704, fig. 1).—Feeding tests showed that sulfuric acid hydrolyzates of zein

prepared under a reflux or under relatively mild conditions in the autoclave possess about the same capacity as does zein to support growth when incorporated in diets supplemented with lysine, tryptophan, histidine, and cystine. More drastic autoclave treatment produced hydrolyzates which did not support growth under similar conditions unless threonine was added. Still more severe autoclaving induced deficiencies which could not be met by threonine supplementation alone. Threonine determinations in several hydrolyzates of zein and casein according to either method showed that threonine is destroyed as the conditions of hydrolysis become more severe. Pure threonine also suffered marked destruction when autoclaved with sulfuric acid under conditions which destroy it in the hydrolysis of zein.

**The effect of conditions of hydrolysis and of prolonged heating upon the optical rotation of sulfuric acid hydrolysates of zein, R. BORCHERS and C. P. BERG** (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 693-696, fig. 1).—During the course of the hydrolysis of zein with aqueous sulfuric acid (14 to 33 percent by volume), either under a reflux or in the autoclave at 120°-180°, no appreciable racemization or destruction of amino acids occurred. Prolonging the refluxing to from 36 to 60 hr. had little or no effect, but autoclaving longer than necessary for hydrolysis induced both racemization and destruction, more markedly so at the higher temperatures. Concentrations of sulfuric acid as low as 8 percent by volume are apparently not suitable for the complete and uncomplicated hydrolysis of zein.

**The lability toward alkali of serine and threonine in proteins, and some of its consequences, B. H. NICOLET, L. A. SHINN, and L. J. SAIDEL** (U. S. D. A.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 609-613).—The authors have demonstrated a reaction by which serine and threonine, when in protein combination, are destroyed in alkaline solution at a rate which is disproportionately greater than any corresponding effect on free serine or threonine. The liberation of additional ammonia, beyond that usually described as "amide ammonia" in the direct hydrolysis, was shown to be quantitatively correlated with the destruction of hydroxyamino acids. The authors believe that the reaction in question involves (e. g., for serine) the formation of dehydroalanyl units in the only partially hydrolyzed protein molecule.

**A synthesis of the aspartic acid analogue of glutathione (asparthione), G. L. MILLER, O. K. BEHRENS, and V. DU VIGNEAUD** (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 411-416).—The tripeptide  $\beta$ -aspartylcysteinylglycine, to which the name asparthione is assigned (differing from glutathione only in that it contains aspartic acid bound through the  $\beta$ -carboxyl group instead of glutamic acid bound through the  $\gamma$ -carboxyl group), has been synthesized. The acid chloride of  $\alpha$ -benzyl-N-carbobenzoxyaspartic acid was condensed with S-benzylcysteinylglycine methyl ester. The resulting ester was saponified, yielding N-carbobenzoxy- $\beta$ -aspartyl-S-benzylcysteinylglycine. This product was then reduced with sodium in liquid ammonia, and the resulting asparthione was isolated through the mercury and copper salts and finally as the free tripeptide.

**Influence of some dietary factors on the development of rancidity in the fat of the white rat, A. OVERMAN**. (Oreg. State Col.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 441-444).—Rats were fed a synthetic diet, one group receiving no supplement, a second group 1 mg. of ascorbic acid daily, and a third group 1 mg. of hydroquinone daily. The results of rancidity tests on fats from each series indicated that the differences in resistance to rancidity are due partly to thinness or fatness of the animal and partly to the diet. Ascorbic acid feeding, together with a low percentage of gain in weight, resulted in a significant increase in resistance of the fat to rancidity.

**The synthesis of some methylated fatty acids**, A. K. SCHNEIDER and M. A. SPIELMAN. (Univ. Wis.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 345-354).—By methods of the use of which examples are given in working detail,  $\alpha$ -methyl acids with even-numbered fundamental carbon chains from  $\alpha$ -methylstearic to  $\alpha$ -methylhexacosanoic acid were synthesized. 10-Methyldocosanoic, 10 methyl-tetracosanoic, and 10-methylhexacosanoic acids were also made. The corresponding amides were prepared as derivatives.

**[Salicylic acid from naphthalene by bacterial oxidation]** (*Pennsylvania Sta. Bul.* 429 (1942), p. 32).—Conversion of naphthalene to salicylic acid by the action of a *Pseudomonas* species and improvement of the yield given by this process are briefly noted by R. W. Stone.

**The acid-splitting reaction of acetoacetic acid and the enzymatic formation of acetic acid from acetoacetic acid**, A. L. LEHNINGER. (Univ. Wis.). (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 147-157).—Acetic acid was the only product obtained when acetoacetic acid was hydrolyzed by strong bases. No other catalyst could be found for the reaction. Rabbit muscle mince formed small quantities of acetic acid from acetoacetic acid, when incubated at 38° for 2 hr. Pure cultures of *Escherichia coli* formed large quantities of acetic acid anaerobically from acetoacetic acid. The catalytic system involved in the muscle mince and the bacteria was thermolabile and possessed other enzyme properties.

**Fixation of carbon dioxide by pigeon liver in the dissimilation of pyruvic acid**, H. G. WOOD, C. H. WEBKMAN, A. HEMINGWAY, and A. O. NIER. (Iowa Expt. Sta. and Univ. Minn.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 31-45).—The dissimilation of pyruvate by pigeon liver was accompanied by fixation of carbon dioxide. By use of  $C^{13}O_2$ , the fixed carbon was shown to be exclusively in the carboxyl groups of the 4-carbon dicarboxylic acids (malate, fumarate, and succinate), the carboxyl adjacent to the carbonyl of  $\alpha$ -ketoglutarate, and the carboxyl of lactate. Aerobically, in the presence of malonate, succinate, which contains little or no fixed carbon, is formed. The theory that the 4-carbon dicarboxylic acids are formed by two mechanisms is proposed, one being reductive through the carbon fixation reaction, the other an oxidative cycle which does not involve citric acid. The scheme accounts for the observed positions of the fixed carbon and the aerobic formation in the presence of malonate of succinate not containing fixed carbon. Possible mechanisms of fixation of carbon in lactate are considered.

**The occurrence of d-amino acids in gramicidin and tyrocidine**, F. LIPMANN, R. D. HORTCHKISS, and R. J. DUBOS (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 163-169, fig. 1).—Enzymatic assay with d-amino acid oxidase indicated that 45 percent of the  $\alpha$ -amino acids of gramicidin hydrolyzates have the d configuration. Tyrocidine appeared to contain d-amino acids amounting to 20 percent of its  $\alpha$ -amino acids.

**The fermentative decomposition of purines by *Clostridium aciduri* and *Clostridium cylindrosporum***, H. A. BARKER and J. V. BECK. (Univ. Calif.). (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 3-27, figs. 3).—The uric acid-fermenting anaerobic bacteria *C. aciduri* and *C. cylindrosporum* were found to decompose only a very few organic compounds, all of which with the exception of glycine, are purine derivatives. Uric acid, xanthine, and guanine were broken down rapidly and completely by cell suspensions and growing cultures, while hypoxanthine and some other compounds liberated their nitrogen slowly and generally incompletely. The products of anaerobic purine decomposition by *C. aciduri* were ammonia, carbon dioxide, and acetic acid, while *C. cylindrosporum* forms in addition small amounts of glycine. Both organisms

decomposed glycine when a fermentable purine was simultaneously available but not otherwise. Glycine was activated as a strong hydrogen donor and appeared to be an intermediate in either purine break-down or carbon dioxide reduction. The reactions produced by these anaerobic bacteria appeared to be oxidations in which carbon dioxide acts as the ultimate hydrogen acceptor and is reduced to acetic acid.

The possibility of using these bacteria for the quantitative and qualitative determinations of uric acid, guanine, and xanthine is pointed out.

The oxidation of phospholipids in the presence of ascorbic acid and carcinogenic chemicals, H. F. DEUTSCH, B. E. KLINE, and H. P. RUSCH. (Univ. Wis.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 529-538, figs. 3).—The oxidation of phospholipides in the presence of ascorbic acid was measured by manometric determinations of oxygen consumption, and the effects of carcinogenic compounds, hydroquinone, and copper on this system were observed. Phospholipide oxidation was catalyzed by the presence of ascorbic acid at pH 4. The catalyzed phospholipide oxidation was inhibited by the presence of carcinogenic compounds and hydroquinone.

Polyuronide hemicelluloses isolated from sap-wood and compression wood of white pine, *Pinus strobus*, L., E. ANDERSON, J. KESSELMAN, and E. C. BENNETT. (Univ. Ariz.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 563-568).—From wood of *P. strobus* cut in eastern Massachusetts during the winter and separated into compression wood and sapwood, pectic material and polyuronide hemicelluloses were isolated both before and after chlorination of the wood. Larger amounts of the hemicelluloses and more mannan free of a uronic acid were obtained from the compression wood than from the normal sapwood, but otherwise the products isolated from the two woods were very similar. Analysis of the wood after the final extractions showed mannan to be still present. The pectic material appeared to be the same as that obtained from hardwoods and to be a pectinic acid. The hemicelluloses isolated from white pine were found to form a complex mixture, apparently of two types, one a mannan free of a uronic acid, the other a monomethyluronic acid combined with a chain of five or six xylan units, which in turn is combined with a series of mannan units. These mannan units appeared to be split off readily. Some fractions which even after purification gave as low as 1 percent carbon dioxide and a correspondingly low percentage of pentosan were obtained. These were apparently combined with larger proportions of mannan.

"While no definite conclusion can be drawn as to the size of the hemicellulose molecule in the cell wall, it must be much larger than those finally isolated. One suggestion is that the carboxyl group of one hemicellulose forms an ester linkage with a hydroxyl group on another hemicellulose, thus leading to the formation of a long branching chain. The outer ends of these chains might be combined by glycosidic union either with mannan or with lignin or other material. If plant materials containing such large molecules were treated with sodium hydroxide solution, the ester linkages would be broken and the smaller molecules would be dissolved out as sodium salts. Treatment of these soluble salts with an acid would lead to more or less hydrolysis of the glycosidic linkages, thus liberating mannan and other materials at the outer end of the chain."

Coenzymes for glyoxalase, O. K. BEHRENS. (Cornell Univ.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 503-508, fig. 1).—Both isoglutathione ( $\alpha$ -glutamylcysteinylglycine) and asparthione ( $\beta$ -aspartylcysteinylglycine) have been demonstrated to be capable of acting in lieu of glutathione as coenzymes for the action of glyoxalase in transforming methylglyoxal to lactic acid. The pH

optimum for the enzyme action proved to be broad and to lie in a similar range for all three substances. Asparthione ( $K_s=3.7\times10^{-3}$ ) was somewhat less effective than glutathione ( $7.4\times10^{-4}$ ), and isoglutathione ( $1.23\times10^{-3}$ ) was considerably less effective. In the presence of optimal amounts of any two of the coenzymes the rate of enzyme action was intermediate between that found with the coenzymes used alone. The extrapolated maximum velocities were approximately the same with all three coenzymes. Cysteinylglycine was without effect as a coenzyme.

**The ultraviolet absorption spectrum of crystalline ribonuclease**, F. M. UBER and V. R. ELLS. (Univ. Mo.). (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 229-230, fig. 1).—The absorption curve, measured with a photometer and tungsten steel spark source, is shown. The molecular extinction coefficient,  $\epsilon$ , defined by the equation  $\epsilon=(1/cd) \log_{10} (I_0/I)$  where  $c$  is the molar concentration and  $d$  is the length of the absorbing solution in centimeter, had a maximum value of 11,540 near 280  $m\mu$  and a minimum of 6,160 at 252  $m\mu$ . Almost identical values were obtained for solutions in phosphate buffer at pH 4.5 and in borate buffer at pH 2.5.

A figure of 9 to 10 tyrosine residues in the ribonuclease molecule could be calculated from the adsorption spectrum data, whereas the presence of 12 was indicated by chemical means.

**A photochemical yield for the inactivation of crystalline trypsin**, F. M. UBER and A. D. McLAREN. (Univ. Mo.). (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 231-237, fig. 1).—The ultraviolet absorption spectrum of crystalline trypsin was found to have a maximum ( $\epsilon=50,000$ ) near 280  $m\mu$ . The number of trypsin molecules inactivated per quantum of radiation adsorbed at 2,537 and 2,804 a. u. were 0.017 and 0.016, respectively, inactivation being defined as the loss of ability to liberate carboxyl groups in  $\alpha$ -benzoyl-L-arginineamide hydrochloride.

[Reports of referees and associate referees on analytical methods] (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 551-745, figs. 5).—The following comprise a part of the reports on analytical methods contributed from the State and Federal institutions respectively noted, from State control and regulatory laboratories, etc., presented at the 1941 meeting of the Association of Official Agricultural Chemists; Plants, by E. J. Miller (p. 551), zinc and iron in plants, by H. Cowling and E. J. Benne (pp. 555-567), copper and cobalt in plants, by L. I. Butler and H. O. Allen (pp. 567-573), and chlorophyll and carotene in plant tissue, by E. J. Benne (pp. 573-591) (all Mich. Expt. Sta.); iodine and boron, by R. H. Hageman, J. S. McHargue, and W. S. Hodgkiss (pp. 552-555) (Ky. Sta.); water, brine, and salt, by A. E. Mix (pp. 591-592); dairy products, by G. G. Frary (pp. 592-594); cheese, by I. D. Garard (pp. 594-601) (Rutgers Univ.); lactic acid, by F. Hillig (p. 602); lactose in milk, by E. R. Garrison and L. D. Haigh (pp. 603-609) (Mo. Sta.); mold mycelia in butter, by J. D. Wildman (p. 609); neutralizers in dairy products, by F. Hillig (pp. 610-612); frozen desserts, by F. L. Hart (pp. 612-617); radioactivity, by A. Wolf (p. 618); cereals, by V. E. Munsey (pp. 618-621); starch in raw and cooked cereals, by M. P. Etheredge (pp. 621-624); chlorine in fat of flour, by D. B. Scott (pp. 624-627); carbon dioxide in self-rising flour, by R. A. Barackman (pp. 627-628); milk solids in bread, by V. E. Munsey (pp. 628-630); proteolytic activity of flour, by Q. Landis (pp. 631-634); carotenoid pigments in flour, by H. K. Parker (pp. 634-638); noodles, by E. O. Haenni (pp. 638-641); oat products, by H. P. Howells (pp. 641-644); barley and rice products, by A. D. Dickson (pp. 645-648), and moisture in self-rising flour and in pancake, waffle, and doughnut flours, by L. H. Bailey (pp. 648-649) (both U. S. D. A.); standard solutions by R. L. Vandaveer (pp. 650-653); constant boiling hydrochloric acid,

by W. H. King (pp. 653-659); standard sodium thiosulfate solutions, by G. M. Johnson (pp. 659-661); thiocyanate solutions, by E. C. Deal (pp. 661-664); sulfuric acid, by H. W. Conroy (pp. 664-667); insecticides and fungicides, by J. J. T. Graham (pp. 667-670), and fluorine compounds, by C. G. Donovan (pp. 670-673) (both U. S. D. A.); sugars and sugar products, by R. F. Jackson (pp. 674-675); the normal weight of invert sugar and a test of Vosburgh's rule, by R. F. Jackson and E. J. McDonald (pp. 675-680); honey and honeydew honey, by G. P. Walton, (pp. 681-689) (U. S. D. A.); flavors and nonalcoholic beverages, by J. B. Wilson (pp. 690-693); organic solvents in flavors, by R. D. Stanley (pp. 693-695); meat and meat products, by R. H. Kerr (pp. 696-697) (U. S. D. A.); spices and other condiments, by S. Alfend (pp. 697-700); volatile oil in spices, by J. F. Clevenger (pp. 700-701); vinegars, by A. M. Henry (pp. 702-705); mustard and mustard products, by J. T. Field (pp. 705-708); fish and other marine products, by H. D. Grigsby (pp. 709-710); total solids and ether extract in fish, by M. Tubis (pp. 710-713); volatile acids, by F. Hillig (pp. 713-714); cacao products, by W. O. Winkler (pp. 714-716); milk proteins in milk chocolate, by M. L. Offutt (pp. 716-717); lecithin in cacao products, by J. H. Bornmann (pp. 717-718); gums in food products, by F. L. Hart (pp. 718-722); soft curd cheese, by M. J. Gnagy (pp. 722-726); oils, fats, and waxes, by J. Fitelson (pp. 726-728); unsaponifiable matter, by G. Kirsten (pp. 728-733); microbiological methods, by A. C. Hunter (pp. 733-735); frozen fruits and vegetables, by H. E. Goresline (p. 736) (U. S. D. A.); nuts and nut products, by M. Ostrolenk (pp. 736-737); canned vegetables, by E. J. Cameron (pp. 738-740); and frozen egg products, by R. Schneider (pp. 740-745).

**Semimicro qualitative analysis (the Barber pressure bulb method), H. H. BARBER and T. I. TAYLOR** (*New York and London: Harper & Bros., [1942], pp. XVI+446, figs. 54*).—Semimicroanalysis, as here defined, uses volumes of solutions ranging from single drops to about 1 cc. Small test tubes, pressure filter tubes, semimicro suction funnels, spot plates, glass slides, and drop-reaction papers are used to carry out the identification tests.

This textbook is divided into three parts, of which part 1, theoretical principles of qualitative analysis, comprises chapters on elementary principles, chemical reactions and equations, theories of solutions and ionization, ionic equilibrium, and precipitation and the dissolution of precipitates. Part 2, covering semimicro qualitative analysis for the detection of cations and anions, contains the three chapters semimicrotechnic, systematic analysis of the cations, and systematic analysis of the anions. Part 3 consists mainly of reference tables showing the properties and reactions of the ions and includes various appendices. A subject index completes the book.

**The determination of sodium in the presence of phosphates, A. E. SOBEL, G. KRAUS, and B. KRAMER** (*Jour. Biol. Chem., 140 (1941), No. 2, pp. 501-508*).—In analyses of sera the concentration of phosphate found in some pathological samples caused high results. Removal of the phosphate by electrodialysis, followed by a determination involving oxidation by a form of the nitric perchloric acid method (E. S. R., 75, p. 153) with the additional use of sulfuric acid, and separation of the sodium as the zinc uranyl acetate salt in a procedure similar to that of Butler and Tuthill (E. S. R., 67, p. 7), gave accurate results.

**Microdetermination of calcium by precipitation as picrolonate and estimation of the precipitated carbon by manometric combustion, D. D. VAN SLYKE and F. J. KREYSA** (*Jour. Biol. Chem., 142 (1942), No. 2, pp. 765-776, fig. 1*).—A micromethod for calcium is described in which the calcium is precipitated as picrolonate and the precipitate, containing 20 atoms of carbon

to 1 of calcium, is estimated from the carbon, which is determined by a rapid manometric wet combustion method. Precipitation and combustion are done without transfer in a single centrifuge-combustion tube. The method serves for estimation of quantities of calcium smaller than can be determined accurately by the usual microprocedures based on titration of the oxalate; 0.2 mg. of calcium or 0.2 cc. of serum suffices for an analysis.

**Rapid methods for determining iodine in soluble iodides and in organic compounds**, G. R. CLARK and J. H. JONES (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 755-760).—The authors modified the method of oxidation by permanganate and titration of the resulting iodate. The manganese dioxide formed in nitric acid was more readily dissolved on adding nitrite than that produced when sulfuric acid was used in the permanganate treatment. Sulfamic acid was found to react with the nitrite more readily than did urea and was, therefore, preferred as a reagent for removing excess nitrite. Separate procedures for soluble inorganic iodides in the presence of traces of chlorides or bromides, for such soluble iodides accompanied by large proportions of chlorides and bromides, and for organic compounds (1) nonvolatile and acid soluble, (2) nonvolatile, insoluble in acids but soluble in bases, and (3) insoluble or volatile organic compounds are described.

**Effect of nitrates on determination of protein nitrogen by Kjeldahl method**, E. I. WHITEHEAD and O. E. OLSON. (S. Dak. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 769-772).—For routine determinations of crude protein, where checks between duplicate titrations of 0.3 cc. are expected and with N/14 hydrochloric acid and N/14 sodium hydroxide as standard solutions, a concentration of nitrate nitrogen in excess of 0.06 percent (0.433 percent potassium nitrate) will result in a significant error. When hays and forages are known to contain considerable nitrate nitrogen, some modified method should be used for the determination of crude protein. This also applies to greenhouse work, as many plants grown under glass have very high concentrations of nitrate nitrogen. Significant errors in the Kjeldahl determination may result when the samples contain nitrates.

**The determination of hydroxylysine in proteins**, D. VAN SLYKE, A. HILLER, and D. A. MACFADYEN (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 681-705, figs. 2).—Hydroxylysine in protein hydrolysates has been determined by precipitating it with the other diamino acids as phosphotungstate and determining the ammonia evolved from the  $\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{NH}_2)\cdot$  group of the hydroxylysine when the diamino acids are treated with alkaline periodate:  $\text{RCH}(\text{OH})\cdot\text{CH}(\text{NH}_2)\text{R}' + \text{NaIO}_4 = \text{RCHO} + \text{R}'\text{CHO} + \text{NH}_3 + \text{NaIO}_3$ . Under the conditions employed for the periodate-ammonia reaction with hydroxylysine, the other amino acids with the  $\cdot\text{CH}(\text{NH}_2)\cdot\text{CH}(\text{OH})\cdot$  group, viz, serine, threonine, and  $\beta$ -hydroxyglutamic acid, also give quantitative yields of ammonia; no amino acid without this group has been found to yield ammonia. In the analysis of protein hydrolyzates for hydroxylysine, the other ammonia-yielding amino acids are completely separated from the hydroxylysine by recrystallization of the diamino acid phosphotungstates. If periodate reacts in a solution containing only hydroxyamino acids, the yields of ammonia are only from 80 to 90 percent of the theoretical, apparently because part of the ammonia condenses with some of the aldehyde that is formed from the rest of the hydroxyamino acid. If a sufficient excess of nonhydroxyamino acid is present, however, a quantitative yield is obtained from the hydroxy acids, presumably because the amino groups of the nonhydroxyamino acids condense with the nascent aldehyde before it can combine with the ammonia. Consequently, in analyses of hydroxylysine an adequate concentration of glycine is added in order to make the ammonia yield quantitative.

In a series of 16 proteins analyzed for hydroxylysine only 6 were found in which hydroxylysine contained over 0.1 percent of the total nitrogen, and in only gelatin and collagen did the amount approach 1 percent of the total protein nitrogen.

**A colorimetric micromethod for the estimation of cystine and cysteine,** B. VASSEL (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 323-336, figs. 2).—Microcolorimetric methods for the estimation of cystine and cysteine are based upon the development of a blue color by heating cystine or cysteine or both in acid solution with *p*-aminodimethylaniline in the presence of ferric ammonium sulfate and determining the percentage absorption at 580.0  $m\mu$  by a spectrophotometer. From 0.01 to 0.20 mg. of cystine or cysteine per cubic centimeter of solution could be estimated, with an average error of  $\pm 3$  percent.

The formation of the typical blue color appeared to require a thiol group and a primary amine separated from each other by two  $-\text{CH}_2-$  groups as found in cystine and cysteine. Reduced glutathione and homocystine did not react to give the blue color. However, they interfered with cystine analyses, apparently by reducing the colored compound to its leuco compound. Ascorbic acid and tyrosine exerted no such effect on the reaction, except that when the former was added after the blue color was formed, reduction of the color to the leuco compound occurred.

**Gasometric determination of carboxyl groups in free amino acids,** D. D. VAN SLYKE, R. T. DILLON, D. A. MACFADYEN, and P. HAMILTON (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 627-669, figs. 6).—In an analytical method for free amino acids,  $\text{CO}_2$  from their carboxyl groups is evolved in a few minutes by reaction with ninhydrin and is measured in the Van Slyke-Neill manometric apparatus (*E. S. R.*, 69, p. 172). The same apparatus and technic serve for micro- and macroanalyses. The precision and rapidity of the method are such that it affords a convenient criterion of the analytical purity of isolated amino acids. Each of the known amino acids yielded by protein hydrolysis evolves at properly chosen pH 1 mole of  $\text{CO}_2$  except aspartic acid and cystine, which evolve 2. Glutamic acid, unlike aspartic, evolves  $\text{CO}_2$  from only one carboxyl group. The  $\text{CO}_2$ -forming reaction is uniquely specific for free amino acids in that it requires the presence, in the free, unconjugated state, of both the carboxyl group and of the  $\text{NH}_2$  or (in proline and hydroxyproline) the  $\text{NH}(\text{CH}_2)$  group. Peptides as a class yield no  $\text{CO}_2$ , or only traces, in the analysis. An exception among peptides is glutathione, in which glutamic acid is so linked that the  $-\text{CH}(\text{NH}_2)\text{COOH}$  group is free.

When combined with the Van Slyke nitrous acid method for amino nitrogen (*E. S. R.*, 26, p. 22), the ninhydrin carboxyl method serves to estimate certain amino acids in mixtures with others. In mixtures of the diamino acids, the excess of  $\text{NH}_2$  over  $\text{COOH}$  serves to measure the lysine plus hydroxylysine. In mixtures of aspartic acid with glutamic acid, alanine, etc., the excess of determinable  $\text{COOH}$  over the  $\text{NH}_2$  or total nitrogen serves as a measure of the aspartic acid. In protein digests carboxyl determinations indicate the amounts of free amino acids formed. Crystalline trypsin was thus shown to digest casein to peptides without liberation of free amino acids.

Chloramine-T as a decarboxylating reagent gives results similar to those from ninhydrin, but less sharply quantitative.

**Determination of free amino acids by titration of the carbon dioxide formed in the reaction with ninhydrin,** D. D. VAN SLYKE, D. A. MACFADYEN, and P. HAMILTON (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 671-680, fig. 1).—Using a primary reaction the same as that employed in the method noted in the preceding abstract, the authors developed a procedure in which the only special apparatus required consists of two 25-cc. Erlenmeyer flasks connected by a

U-tube. The reaction occurs in one flask; the CO<sub>2</sub> then distills in vacuo during 2 to 3 min. into standard barium hydroxide in the other flask, where the excess hydroxide is titrated. The same apparatus serves for macro- and micro-analyses.

For amounts of carboxyl carbon above 0.4 mg. the mean variability of results is of the order of  $\pm 0.3$  percent of the amounts measured. Microanalyses with samples down to 0.04 mg. of carboxyl carbon can be done with a mean error under 1 percent.

The application of the skatole color reaction to the determination of fructose in blood, R. M. REINECKE. (Univ. Minn.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 487-490).—This color reaction was found to be quite sensitive but subject to a marked degree of inhibition by dilution with the protein-free blood filtrate. Using ethanol saturated with hydrogen chloride gas in place of the aqueous acid obviated this difficulty, but an interfering color due to the alcohol had to be avoided by heating the alcoholic acid and the sample together before rather than after adding the skatole, the acid alcohol and sample mixture being cooled before adding the color-producing reagent. Carried out as here directed, an accurate determination of 5 $\gamma$  of fructose was possible, and as much as 80 $\gamma$  of glucose did not cause appreciable interference.

Elimination of errors in the colorimetric assay of neutral urinary 17-ketosteroids by means of a color correction equation, N. B. TALBOT, R. A. BERMAN, and E. A. MACLACHLAN (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 211-218, figs. 3).—The authors show that interfering chromogenic substances may cause significant and variable errors of overestimation in the colorimetric assay of neutral urinary 17-ketosteroids. Except in unusual instances, these errors may be largely eliminated by means of a simple color correction equation without preliminary chemical purification of the crude neutral extract.

The quantitative determination of cytochrome *c*, V. R. POTTER and K. P. DuBois. (Univ. Wis.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 417-426).—In a new method for the determination of cytochrome *c* in small quantities of tissue from experimental animals, customary methods of extraction are used but concentration is effected by precipitation with trichloroacetic acid. The determination is based on the quantitative spectrophotometric measurement of the change in extinction when cytochrome *c* is oxidized and reduced by specific enzymes. Results obtained with normal rat tissues and chick embryo are recorded.

Estimation of phenols in meat and fat, I. W. TUCKER. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 779-782).—A sample of 50 gm. of the meat or fat was extracted with 200 cc. of a mixture of equal volumes of alcohol and water, the filtrate being chilled and refiltered to remove most of the fat. If the extracts were highly colored, the color was removed prior to the second filtration by the addition (without heating) of a little decolorizing carbon. To a 5-cc. sample of extract (previously diluted with water if the quantity of phenol expected was large), 5 cc. of 0.5 percent solution of sodium borate (Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O) and 1 cc. of 2,6-dichloroquinonechloroimide solution (0.05 percent in 7 percent alcohol) were added. After standing for an hour at room temperature the blue indophenol was extracted with 15 cc. of *n*-butyl alcohol. After the aqueous layer had been drained off, 2 cc. of butyl alcohol saturated with NH<sub>3</sub> was added. The butyl alcohol containing the dye was then measured and brought to a definite volume in order to correct for any volume changes due to the mutual solubilities of water, butyl alcohol, and ethyl alcohol. After the butyl alcohol layer had been filtered through paper the color intensity was read in a colorimeter, a filter transmitting at about 635 m $\mu$  being used,

**Modification of Lane-Eynon method for sugar determination,** A. C. HILBRETH and G. B. BROWN. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 775-778).—To adapt the method to rapid routine work on numerous samples, an aliquot of the unknown sample is added directly to a measured quantity of standardized Fehling's solution (the quantity of sugar in the aliquot being less than the amount necessary to reduce all the copper in the Fehling's solution). Reduction is completed by titrating into the boiling mixture a standard solution of inverted sucrose. The quantity of sugar in the unknown is calculated from the amount of standard sugar solution necessary to complete the reduction of copper. Advantages of this modification are (1) use of a standard solution for all titrations, and (2) elimination of the cleaning or changing of burets between determinations. The modified procedure was compared with that of Quisumbing and Thomas (*E. S. R.*, 46, p. 113) and with a ceric sulfate method, satisfactory agreement being obtained.

**A modification of the Official method for the determination of nicotine in tobacco,** K. E. RAPP, C. W. WOODMANSEE, and J. S. McHARGUE. (Ky. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 3, pp. 760-763).—A direct weighing of the nicotine silicotungstate after drying at 100° C. is substituted for the weighing of the ignited oxides. Time and attention required are decreased, and no loss of accuracy was detected.

**A colorimetric reaction for testosterone,** V. L. KOENIG, F. MELZER, C. M. SZEGO, and L. T. SAMUELS. (Univ. Minn. et al.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 487-493, figs. 2).—The sample to be tested, dry or in about 0.4 cc. of 95-percent alcohol, is treated at ice-bath temperature with 2 cc. of sulfuric acid and carefully mixed therewith. The tube is then heated for 2 min. in boiling water and returned to the ice bath. After 5 min., 2 cc. of saturated aqueous thiocol (potassium gualacolsulfonate) and 0.3 cc. of 1-percent aqueous copper sulfate are added with stirring. The tubes are reheated in boiling water for 2 min., during which period they are stirred three times. The tubes are again placed in the ice-water bath and diluted to the 10-cc. mark with 50 percent sulfuric acid. After being transferred to a colorimeter tube, the solution is read against a blank containing the reagents, but not the hormone, in an Evelyn colorimeter equipped with a 635-m $\mu$  filter.

A calibration curve shows the light absorption by various quantities of testosterone with the 635 m $\mu$  filter. Spectral absorption studies of the colored compound showed that its maximum absorption is at about 639 m $\mu$ .

Androsterone and dehydroandrosterone did not interfere appreciably with the testosterone color. Of the 18 compounds besides testosterone tested, only  $\Delta^4$ -androstenedione-3,17, testosterone propionate, and testosterone oxime gave the reaction.

**A low temperature wet ashing method applied to the study of the electrolyte composition of the ventricular musculature and lung parenchyma of the dog,** E. H. WOOD. (Univ. Minn.). (*Jour. Biol. Chem.*, 143 (1942), No. 1, pp. 165-170).—The method consists of a preliminary digestion with nitric acid, followed by a perchloric-sulfuric acid mixture, the digestion then being completed with hydrogen peroxide. Results of determinations of various mineral constituents of the tissues named and of the blood serum after oxidation of organic matter by the method described are recorded.

**Influence of solvent on the ultraviolet absorption maximum of vitamin A,** K. MORGAREIDGE (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 9, pp. 700-702).—"With the aid of the Beckman quartz photoelectric spectrophotometer, the question of the influence of solvent on the ultraviolet absorption maximum of vitamin A has been reexamined. Special reference is made to differences

in behavior between ester and alcohol forms of the vitamin. A polar solvent results in high values and a shift of peak to shorter wave lengths as compared to data obtained in a nonpolar solvent. This effect is most pronounced for samples of unsaponifiable fractions of oils or vitamin A alcohol. The anomalous behavior of the U. S. P. reference cod-liver oil is pointed out, and the significance of the commercial standard conversion factor is discussed."

**A fluorimetric method for the estimation of riboflavin in foodstuffs,** M. SWAMINATHAN (*Indian Jour. Med. Res.*, 30 (1942), No. 1, pp. 23-35).—The method described in some detail as to reagents, apparatus, procedure, and calculations is an indirect one, directed on the one hand at removing interfering coloring matter that absorbs part of the activating and fluorescent light, thus causing the results to be too low, and on the other hand at removing blue fluorescent substances that interfere with accuracy in the opposite direction. The method adopted includes the following steps: (1) Extraction of the food material three times with hot 0.05 N  $H_2SO_4$ ; (2) removal of coloring matter by the addition of a slight excess of N lead acetate in N acetic acid solution; (3) absorption of the riboflavin on fuller's earth; (4) elution of the riboflavin, using 50 percent aqueous alcohol containing sufficient NaOH to make a concentration of 0.25 N; (5) destruction of the riboflavin in one-half the eluate by treatment with 0.1 N NaOH at 100° C. in a water bath (this does not destroy the blue fluorescent materials associated with riboflavin in purified extracts of biological materials); (6) decolorization of the eluates by oxidation with cold dilute  $KMnO_4$ , and the excess of  $KMnO_4$  with  $H_2O_2$  (this destroys the interfering coloring matter but not the riboflavin), followed by adjustment of the pH to 5 and dilution to known volume; and (7) estimation of the riboflavin present by a fluorimeter, applying the necessary corrections. Values obtained by application of the method to representative foods (4 cereals, 2 legumes, 2 vegetables, 2 fruits, rice polishings, and 3 samples of dried yeast) appeared to correspond well with the results of biological assays reported in the literature. Dried yeast contained from 27.5 to 64.8  $\mu g$  per gram, but other foods were generally poor in the vitamin, legumes (1.8-2.5  $\mu g$ .) and whole wheat (1.2  $\mu g$ .) being somewhat superior to the others.

**Fluorimetric estimation of riboflavin in urine,** M. SWAMINATHAN (*Indian Jour. Med. Res.*, 30 (1942), No. 1, pp. 37-43).—Urines or urine extracts purified by the procedures of absorption on fuller's earth, elution, and decolorization contained varying amounts of coloring matter and blue fluorescent substances, so that procedures essentially the same as those described above for foodstuffs were adopted to allow for the interference caused by these colored and fluorescent substances. The calculations essential for making these corrections are illustrated by specific example. The daily excretion of riboflavin in a normal subject is reported to range from 320 to 360  $\mu g$ . After oral ingestion of test doses of from 1 to 10 mg. of riboflavin, about 80 to 85 percent of the test dose is excreted in the following 24 hr.

**Pasture studies.—XXIII, A proposed modification of the fluorimetric method for the estimation of riboflavin,** R. A. CHAPMAN and W. D. McFARLANE (*Canad. Jour. Res.*, 20 (1942), No. 5, Sect. B, pp. 82-86, fig. 1).—The fluorimetric method for the determination of riboflavin in foodstuffs was modified to permit the use of the fluorimeter described by Froman and McFarlane (*E. S. R.*, 86, p. 10). Extracts were prepared by enzymatic digestion and purified by barium chloride precipitation and benzyl alcohol extraction. Photochemical reduction of riboflavin in the blank was effected by stannous chloride in benzyl alcohol solution. Recovery experiments conducted on a number of products showed that quite constant readings could be obtained on aliquots of the same extract, and that recoveries of added riboflavin were good. The possibility of

destruction of riboflavin during the enzymatic digestion was shown to be negligible, since a 98.5-percent recovery of riboflavin was obtained when a pure riboflavin solution was carried through the entire procedure. The riboflavin content of a variety of materials as determined by the modified procedure is reported.

**The chemical determination of thiamine, E. R. KIRCH and O. BERGEIM.** (Univ. Ill.). (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 575-588, figs. 2).—The chemical method developed for the determination of thiamin involved the reaction of the vitamin with diazotized ethyl *p*-aminobenzoate to form a stable pink to red colored compound which was quantitatively extracted from the aqueous solution by isoamyl alcohol. Maximum color was developed in 2 min. and results were reproducible, with readings on the Pulfrich photometer increasing proportionally with increase in the concentration of the thiamin. Tests of the reagent with a wide variety of compounds and with vitamins A and D showed that they offered no interference. Ascorbic acid, however, partially or entirely prevented color development, so that in the presence of this vitamin a modification was developed to permit preliminary oxidation of the ascorbic acid with 1 percent  $\text{KMnO}_4$  (in acid solution). The method was found to be specific for free thiamin. The pyrophosphate of thiamin did not give the test, and the ester had first to be hydrolyzed to free the vitamin. This was accomplished in the case of yeast preparations by the action of the phosphatase in the yeast. This enzyme was liberated from the yeast cells by heating the yeast suspension in water or 30-percent ethyl alcohol at a temperature of boiling water for 2 or 3 min. A modification of the procedure was developed to make the test applicable to the estimation of thiamin in urine without any adsorption of the vitamin.

**A modified micro-fermentation method for the estimation of thiamine, E. S. JOSEPHSON and R. S. HARRIS** (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 9, pp. 755-756).—The method for the microestimation of thiamin in tissues and tissue fluids is described in detail as to reagents, preparation of samples, and fermentation procedure. It is based on the method of Schultz et al. (*E. S. R.*, 88, p. 293), and represents a revision using the Warburg technic. Interference by nonthiamin substances is corrected by sulfite treatment, and residual sulfite is eliminated by a peroxide treatment. This procedure is particularly applicable to the assay of tissues and fluids low in thiamin ( $10^{-8}$  gm. of thiamin per cubic centimeter) and in the measurement of thiamin degradation products in tissue metabolism and in the treatment of foods. Repeated estimations often show agreement within 2 percent, and the results agree within 5 percent with those by fluorometric assay.

**Photoelectric determination of dl- $\alpha$ -tocopherol in serum, G. G. MAYER and H. СОВЕТКА** (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 695-699).—The method described is an adaptation of that of Emmerie and Engel (*E. S. R.*, 82, p. 15), and consists essentially in alkaline digestion of the serum and introduction of formaldehyde and 95-percent ethyl alcohol into the digest, followed by a triple ether extraction. The ether of the washed and dried extract is replaced by benzene and this solution passed through a floridin column for the removal of carotenoids. The colorless filtrate is treated with ferric chloride- $\alpha, \alpha'$ -bipyridine reagent, and the color is read in a Pulfrich photometer. The concentration in the serum is determined from this reading by reference to a curve constructed from the galvanometer reading of standard dl- $\alpha$ -tocopherol solutions. Satisfactory agreement in duplicate determinations and recoveries from 77 to 115 percent were obtained in the application of the method to 10 cc. or less of various serum samples. The level of tocopherol in normal human serum varied from 0.6 to 1.4 mg. per 100 cc.

**On the colorimetric method for the determination of the K vitamins**, J. V. SCUDR and R. P. BUHS (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 665-669, figs. 3).—The interference of slowly reducing tocopherylquinones upon the performance of the colorimetric oxidation-reduction method for the determination of the K vitamins (*E. S. R.*, 87, p. 626) was investigated. It was shown that the error caused by this interference can be eliminated by extrapolation of the transmittance time curves to zero time.

**The calcium phosphate precipitate in limed cane juice**, H. P. KORTSCHAK (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 46 (1942), No. 3, pp. 105-109).—The investigation reported upon yielded the following findings:

Calcium phosphate as precipitated by liming cane juice is not a definite compound. After precipitation, the calcium content of the precipitate is increased by absorption of calcium hydroxide from the juice. When the juice and precipitate are heated, the pH drops, due to oxalation of the precipitate. Three major reasons for the high calcium content of clarified juice are (1) the original calcium concentration, (2) replacement of precipitated magnesia by lime, and (3) the reduced activity of the calcium ion.

## AGRICULTURAL METEOROLOGY

**Nocturnal wind-velocity, eddy-stability, and eddy-diffusivity above a citrus orchard**, R. A. KEPNER, L. M. K. BOELTER, and F. A. BROOKS. (*Calif. Expt. Sta.*). (*Amer. Geophys. Union Trans.*, 23 (1942), pt. 2, pp. 239-249, figs. 4).—The study (1938-39) concerns analytical considerations for velocity profile, relations of velocity to height, velocity distribution, and atmospheric eddy-stability and diffusivity including mathematical treatment of the subject, with formulas. Undertaken with special reference to orchard heating, the observations were made largely during nights when there was a definite inversion and relatively low wind velocities. The conditions prevailing during nights when orchard heating studies were conducted at Riverside, Calif., were generally those of great stability or nearly so. The least stability occurred just above the tree tops. Although the gradient of temperature inversion is greatest in this region, the wind velocity gradient is also here at its maximum. In the case of density flow of cold air beneath stationary warm air, the velocity gradient would go to zero at some height, resulting in eddy decay. This condition favors the development of strong inversions. The stability criterion is decreased when the wind velocity increases or when the temperature inversion decreases below about 10° F. temperature difference between 5- and 60-ft. elevations.

**The problem of the intensity-frequency of rainfall of varying duration over any given drainage area**, T. E. W. SCHUMANN (*Amer. Met. Soc. Bul.*, 23 (1942), No. 8, pp. 328-341, figs. 2).—Reliable information on the frequency of heavy or excessive precipitation is the first requisite for computing the runoff. This paper discusses the various factors on which the intensity of rainfall depends, including its relations with duration, the period *N* (number of years in which rainfall of maximum intensity in inches per hour occurs), and the area over which the rain falls. Methods of presenting such data are discussed, and formulas are presented.

**The sunspot-period and spring rainfall in the United States**, H. H. CLAYTON (*Amer. Geophys. Union Trans.*, 23 (1942), pt. 2, pp. 284-286, figs. 2).

**Monthly Weather Review**, [September-October 1942] (*Mo. Weather Rev. [U. S.]*, 70 (1942), Nos. 9, pp. 203-224, pls. 10, figs. 16; 10, pp. 225-248, pls. 10, figs. 8).—In addition to meteorological, climatological, solar radiation, and sunspot data, No. 9 contains Comparative Observations with Friez-Type Radio-

sondes and Fergusson Meteorographs, by L. F. Hafer (pp. 203-208), and Precipitation Departures October 1941-July 1942 (pp. 208-209); and No. 10, A Study of Atmospheric Pollution, by W. F. Davidson (pp. 225-234).

**Annual meteorological report** (*Alaska Stas. Prog. Rpt. 1938-41*, pp. 15-16, 32-33).—The cardinal points of temperature, total precipitation, snow in inches, and cloudy, partly cloudy, and clear days annually and by months for the calendar years 1938-41 at the Fairbanks and Matanuska Stations are tabulated.

**Meteorological observations, [1942]**, C. I. GUNNESS ET AL. (*Massachusetts Sta. Met. Ser. Buls. 637-648 (1942)*, pp. 4 each).—These are the usual summaries of observations for each month at Amherst, Mass., with brief notes on the more significant features.

The December number contains an annual summary for 1942, which shows that the mean pressure for the year was 30.004 in.; the mean temperature 48.8° F., as compared with the normal of 47.4°, highest 93° July 19, lowest -15° December 20-21; total precipitation 47.85 in., as compared with the normal 43.7 in., snowfall 33.75 in., as compared with the normal of 47.78 in.; mean cloudiness 55 percent, bright sunshine 58.5 percent; last frost in spring May 11, first in fall September 29; last snow April 11, first November 27.

**Climatological data for the period 1911 to 1940, inclusive, for the Wind River Weather Station, Skamania County, Washington**, W. J. ALLYN ET AL. (*U. S. Dept. Agr., Forest Serv., Pacific Northwest Forest and Range Expt. Sta., 1941*, pp. [1]+23).—Following detailed statements on such matters as the location of this meteorological station, its history, and the methods used, tabulations are presented relative to significant averages and extremes, mean temperatures, average maximum and minimum and average minimum and minimum temperatures, relative and minimum relative humidity, frost-free season, precipitation, snowfall and depth of snow, number of days of precipitation, wind movement, state of the weather (clear, partly cloudy, or cloudy), thunderstorm days, evaporation, wind movement over evaporation tank, and soil temperatures.

**Hydrologic studies: Compilation of rainfall and runoff from the watersheds of the Shelby Loam and Related Soils Conservation Experiment Station, Bethany, Missouri, 1941**, A. W. ZINGG. (Coop. Mo. Expt. Sta.). (*U. S. Dept. Agr., Soil Conserv. Serv., 1942, SCS-TP-39, Sup. 1*, pp. [31], pls. 18).

**Hydrologic data: North Appalachian Experimental Watershed, Coshoc-ton, Ohio, 1940**. (Coop. Ohio Expt. Sta. et al.). (*U. S. Dept. Agr., Hydrol. Bul. 4 (1942)*, pp. III+338, pls. 4, figs. 12).

## SOILS—FERTILIZERS

[**Soil and fertilizer investigations of the Bureau of Plant Industry**] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1942*, pp. 17-18, 21-24).—C. S. Scofield reports progress on determining the water requirements of crop plants by using tensiometers as a guide in irrigation farming and the use of alfalfa for detecting a boron deficiency in the soil. R. O. E. Davis reporting on soils and fertilizer investigations discusses special services being done that are contributing to the war, high-analysis fertilizers, and progress of experiments designed to determine the chemical nature of soil growth substances. C. E. Kellogg points out the importance of soil surveys in wartime adjustments and presents a summary of areas surveyed and mapped during the fiscal year 1942.

[**Soils investigations by the Georgia Station**] (*Georgia Sta. Rpt. 1942*, pp. 23-29, 63-66, figs. 4).—Data on the available potash and available phosphate in

surface soils of Georgia are presented by means of maps of the State showing the pounds of available  $K_2O$  and available  $P_2O_5$  and number of areas sampled. Progress on correlation of chemical soil tests with response of cotton to potash and lime and with response of cotton to phosphate and lime is summarized. Miscellaneous soil tests on pasture areas are also presented.

[**Soils investigations by the Kansas Station.**] (Partly coop. U. S. D. A.). (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 15-17).—Progress on soil fertility investigations is summarized by W. H. Metzger; influence of the absolute reaction of the soil solution upon the growth and activity of *Azotobacter*, by P. L. Gainey; the influence of legumes and free-living organisms on the growth of plants and on the nitrogen balance of Kansas soils, by H. E. Myers; the storage, utilization, and evaporation of soil moisture, by J. C. Hide; and a study of the soil solution as governed by H-ion concentration and other factors and a study of replaceable cations and anions in some Kansas soils, both by A. T. Perkins.

[**Soils and fertilizer investigations by the Oregon Station.**] (Partly coop. U. S. D. A. et al.). (*Oregon Sta. Bul. 401 (1941)*, pp. 23, 75-77).—Progress is reported on tests designed to determine the fertilizing value of turkey feathers. Increases in yield of corn and artichokes were obtained by using feathers.

Progress in soils work briefly presented include soil fertility trials, potassium in relation to soils and plant nutrition, minor elements in plant nutrition, drainage and improvement of heavy or alkaline soils, nitrate investigations as related to soil moisture, and effect on plant growth of irrigating soils with waste sulfite liquor.

[**Soil investigations by the Pennsylvania Station**] (*Pennsylvania Sta. Bul. 429 (1942)*, pp. 32-34).—Soil structure is noted by F. G. Merkle as an important item in soil fertility; C. F. Noll calls attention to lime and phosphorus as primary soil needs; and J. W. White points out the improvement in yield of common grain crops by the use of lime and the variation of the lime requirements of legume crops.

[**Soil investigations by the Utah Station**] (*Farm and Home Sci. [Utah Sta.], 3 (1942), No. 4*, pp. 8, 10).—Information is presented on the effect of irrigation water on soil erosion, the effect of lining irrigation canals on conserving water, and a system of economic classification of irrigated farm lands from correlation studies of the Uinta Basin.

**Preparing soil profile mounts: Method and demonstration, M. DROSDOFF.** (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), p. 30).—A method of preparing soil profile mounts is described. The method consists of applying a film of clear lacquer to a rectangular piece of pasteboard and sprinkling on it an excess of dry soil.

[**Soil Survey Reports, 1935 and 1936 Series**] (*U. S. Dept. Agr., Bur. Plant Indus. [Soil Survey Rpts.], Ser. 1935, No. 23*, pp. 113, pls. 4, figs. 2, map 1; 1936, No. 13, pp. 67, pls. 3, fig. 1, map 1).—These surveys were made in cooperation with the California and Utah Experiment Stations, respectively: 1935, No. 23, Pixley area, Calif., R. E. Storie et al.; and 1936, No. 13, Virgin River Valley area, Utah-Ariz., F. O. Youngs et al.

**The moisture potential of soils, P. R. DAY.** (Univ. Calif.) (*Soil Sci.*, 54 (1942), No. 6, pp. 391-400).—The author defines the moisture potential as the chemical potential of water in ergs per gram, a quantity identical with the partial molal free energy of water in all respects except for the unit of mass employed. In accordance with previous terminology, the moisture potential of an aqueous solution is called the "osmotic potential." A general relationship between composition and osmotic potential is presented, and methods of calcula-

tion are discussed. It is shown that the moisture potential of a soil may be calculated from tensiometric, centrifugal, or pressure-membrane methods, provided the osmotic potential and the partial specific volume of water in the liquid phase are known. The theory of the cryoscopic method is developed, and an equation similar to that of Schofield and Botelho da Costa (E. S. R., 81, p. 174) is derived. A comparison of cryoscopic data with data from static vapor-pressure measurements demonstrated that the freezing method must be further improved before results completely consistent with thermodynamics can be obtained. A possible explanation of the discrepancies is that irregular freezing results in excessive withdrawal of water from the liquid phase in the localized areas in which ice crystals have formed.

**The influence of porosity of some orchard soils upon root behavior, A. T. KNIGHT.** (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 23-26, figs. 2; *abs. in Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, p. 180).—Artificial soil-sand mixtures and undisturbed soil cores were used to investigate some of the fundamental effects of soil erosion as determined from the growth of alfalfa roots.

**Aggregation of an orchard soil under sod, mulch, and cultivation, A. L. HAVIS.** (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), p. 28).—The degree of aggregation of the A and B horizons of Wooster silt loam was determined for areas that had been under sod, mulch, and cultivation for long periods of time. From 2 to 6 yr. of the above treatment gave little differences in aggregate size distribution. The author thus suggests that only relatively long-time treatments result in the larger soil aggregates, and that the number and stability of the aggregates was increased more quickly under the mulch than under bluegrass sod.

**A study of the effects of silty irrigation water from an intermittent stream on crops and soils in controlled plots, J. L. GARDNER and D. S. HUBBELL.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 12, pp. 1090-1101, figs. 3).—Three years' results with corn, beans, and oats grown on plats watered with silty water are compared with the same crops grown on plats watered with clear water. The workers conclude that good crops can be obtained by irrigating with the relatively clearer of the intermittent arroyo flows and at the same time the land surface will not be raised so as to make cultivation impracticable. Plats watered with every flow had not differed significantly in crop yields from those watered with the clearer water, but the amount of sediment deposited indicates that continuation of this type of irrigation practice would be important because of the raising of the soil surface.

**The influence of periodic close grazing and pasture fertilization upon erosion control, D. B. JOHNSTONE-WALLACE, J. S. ANDREWS, and J. LAMB, JR.** (U. S. D. A. coop. [N. Y.] Cornell Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 11, pp. 963-974, figs. 4).—This article summarizes investigations on the effect of fertilizers, lime, and close grazing with sheep on soil and water conservation, animal gains, and plant species changes on Lordstown flaggy silt loam and Bath flaggy silt loam soil under the climatic conditions prevailing at the high altitudes in southern New York.

**Stubble-mulch farming for soil defense, L. S. CARTER and G. R. MCDOLE** (U. S. Dept. Agr., *Farmers' Bul.* 1917 (1942), pp. 11+24, figs. 26).—An illustrated publication presenting information on advantages of, and methods and equipment for putting into effect, a system of stubble-mulch farming.

**The maintenance of soil productivity (Montana Sta. [Bien.] Rpt. 1941-42, pp. 10-11).**—The effect of different soil management systems on soil productivity under dry land and irrigated land conditions is discussed by A. H. Post.

**The fractionation of the organic matter, including nitrogen, of certain soils and its relation to their quality**, M. R. F. ASHWORTH (*Jour. Agr. Sci. [England]*, 32 (1942), No. 4, pp. 349-359).—Proximate determinations of the organic fractions in the upper layers of seven different soil profiles, ranging from grassland to forest and peat soils, are reported.

**Changes occurring in the organic matter during the decomposition of compost heaps**, M. R. F. ASHWORTH (*Jour. Agr. Sci. [England]*, 32 (1942), No. 4, pp. 360-372, figs. 13).—The decomposition of composts of grass, straw, and two peats made up to the same nutrient content was studied by means of taking samples from compost heaps of the different materials at intervals.

**The forest humus layers of Ohio**, L. W. GYSEL (*Ohio State Univ., Abs. Doctoral Diss.*, No. 38, (1942), pp. 167-175, fig. 1).—The more important forest humus layers of Ohio are classified and described. Physical and chemical properties of the forest humus layers are given.

**The nature and properties of peats in New Jersey**, S. A. WAKSMAN and H. B. SCHULHOFF. (N. J. Expt. Stas. et al.). (*Soil Sci.*, 54 (1942), No. 6, pp. 447-461, fig. 1).—This paper presents a survey of the peat resources of the State of New Jersey, a type of land covering about 8 percent of the total surface area and varying greatly in depth, origin, and chemical composition. The peat types of the State are divided into four groups—sedge and reed peat, forest peat, fresh-water alluvial peat, and tidal marsh. Moss peat is entirely absent, although sphagnum is growing on the surface of many peat areas in the State. The sedge and reed, or lowmoor peats, predominate in the northern or glacial areas of the State, whereas the forest peats and the salt marshes predominate in the southern or Coastal Plain areas.

The peats have been extensively utilized for various agricultural and industrial purposes, depending upon the nature of the specific variety and upon the drainage conditions and geographical location of the bogs.

**Lime and legumes produce good yields on both fertile and poor silt loam soils**, H. B. VANDERFORD (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 12, p. 7).—General factors to be considered in liming various soils and crops are presented, along with data on the effect of lime on soil acidity and crop yields.

**Carbon-nitrogen ratios in organic fertilizer materials in relation to the availability of their nitrogen**, E. J. RUBINS and F. E. BEAR. (N. J. Expt. Stas.). (*Soil Sci.*, 54 (1942), No. 6, pp. 411-423).—A series of 34 organic ammoniates and waste organic materials were tested with regard to the availability of their nitrogen. Ratings of these materials, particularly of their insoluble nitrogen, were made by vegetative, nitrification, and permanganate methods. A study as to the applicability of the principle of the C:N ratio in explaining the estimated availability of the nitrogen of these materials indicated that this is a valuable supplemental aid in determining the quality of the nitrogen in these materials. In some instances it was found necessary to apply a correction to the C:N ratio by eliminating the carbon of the lignin in the material. For certain materials, however, the application of this correction factor failed to bring the products into line with the known availability of their nitrogen.

**Loss of ammonia from ammonium sulfate applied to alkaline soils**, T. N. JEWITT (*Soil Sci.*, 54 (1942), No. 6, pp. 401-409, fig. 1).—Gaseous ammonia was found to be lost in considerable quantities when ammonium sulfate was applied to certain alkaline Sudan soils. The loss takes place over long periods from the moist soil at a rate greatly influenced by the rate of application of the fertilizer and little influenced by the moisture content, except near the air-dry condition. The author suggests a mechanism for the loss, according to which the base-exchange equilibrium in the soil tends to maintain the con-

centration of ammonia in the soil solution at a constant level, whereas the normal buffered state of the soil solution maintains constant the hydroxyl-ion concentration. Under these circumstances the ammonia is lost as from a dilute solution at a constant rate proportional to the ammonia concentration in the soil solution. This loss will continue (if the soil is kept moist) for a long or short period, depending on the reserves of ammonium ions in the base-exchange complex. If the exchange capacity is low, the rate of loss of ammonia is not maintained constant and is comparable with that from a dilute solution, the ammonia content of which declines progressively as evaporation proceeds. It is considered probable that commercially important losses of ammonia occur in the field when ammonium sulfate is broadcast on alkaline soil.

**Enzymatic vs. microbial concepts of urea hydrolysis in soils,** J. P. CONRAD. (Univ. Calif.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 12, pp. 1102-1113, figs. 2).—Additional information is presented on investigations attempting to determine whether micro-organisms or enzymelike substances bring about urea hydrolysis in the presence of toluene and other antiseptics.

**Small amounts of phosphate, potash: Yazoo River soils,** R. KUYKENDALL. (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 12, p. 7).—The author points out the advisability of applying some form of nitrogen every year and potash and phosphorus occasionally to take care of any deficiencies that might exist in the soils near the Yazoo River.

**Dephosphorylation of organic phosphorus compounds by soil catalysts,** H. T. ROGERS. (Iowa Expt. Sta.). (*Soil Sci.*, 54 (1942), No. 6, pp. 439-446, fig. 1).—Calcium glycerophosphate when incubated at pH 4.0 and 45° C. in toluene-treated soil underwent 66 percent mineralization in 18 hr. from an initial concentration of 210 p. p. m. of organic phosphorus. Dephosphorylation of nucleic acid by soil catalysts was only about one-third as rapid as the break-down of calcium glycerophosphate when optimum conditions for the respective systems were maintained. The optimal reaction (pH 6.2-7.0) and temperature (about 60°) for the dephosphorylation of nucleic acid by soil catalysts were found about the same as the optima for the root-borne nuclease system. The significance of the presence in soils of catalysts capable of dephosphorylating organic phosphate compounds is discussed, with special reference to the possible value of organic phosphate fertilizers in obtaining better penetration of phosphates in soils.

**The beneficial effect of preliming upon  $\text{PO}_4$  uptake from incorporations of monocalcium phosphate,** W. H. MACINTIRE and B. W. HATCHER. (Tenn. Expt. Sta. et al.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 11, pp. 1010-1016).—The effect of preliming with  $\text{CaCO}_3$  upon the recovery of  $\text{P}_2\text{O}_5$  of subsequent additions of water-soluble monocalcium phosphate was determined for 35 soils which included 12 subsoils and eroded phases. The authors conclude that the results indicate the advantage of preliming as a means of a more effective utilization of incorporations of superphosphate.

**Soil liming investigations.—VI, Response of crimson clover to boron with and without lime on Coastal Plains soils,** J. A. NAFTEL. (Ala. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 11, pp. 975-985, figs. 8).—In continuation of this series (E. S. R., 78, p. 309), results of this investigation indicate that growth of crimson clover on the lower Coastal Plains soils and on other soils low in boron was benefited by including boron in the fertilizer.

**The production of a lime-induced manganese deficiency on an eroded Kentucky soil,** G. D. SHERMAN, J. S. MCHARGUE, and W. S. HODGKISS. (Ky. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 12, pp. 1076-1083, fig. 1).—Liming an acid clay soil, having an extremely low manganese content, to a neutral or alkaline reaction was found to bring about a manganese deficiency.

**Zinc relationships of some Utah soils**, D. W. THORNE, W. D. LAWS, and A. WALLACE. (Utah Expt. Sta.). (*Soil Sci.*, 54 (1942), No. 6, pp. 463-468).—The authors find that in Utah the zinc-deficiency symptoms usually appear on fruit trees growing on noncalcareous soils derived principally from granite, gneiss, quartzite, or related rocks, and have not been observed on soils derived principally from limestone. The zinc content of calcareous soils was found to be almost twice that of noncalcareous soils. Samples of rock which serve as parent materials for noncalcareous soils contained about the same amount of zinc as samples of various formations of limestone. The zinc in the granite, gneiss, and quartzite samples studied was more soluble than that in limestone. Apparently zinc is lost more rapidly from silicate rocks than from limestone rocks during weathering processes. In the soils studied, no consistent correlations were found between values for any of the four factors determined—total zinc, available zinc, organic matter, and pH.

**Complete fertilizer needed by soils of south Mississippi**, R. COLEMAN (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 12, p. 7).—A complete fertilizer, high in potash, gave the most profitable production of cotton, but it is suggested that a good crop of Austrian Winter peas fertilized with basic slag can largely replace the nitrogen and phosphorus for Brandon silt loam.

**Commercial fertilizers, 1942**, E. R. TOBEY (*Maine Sta. Off. Insp.* 185 (1942), pp. 41-80).—Analytical data resulting from the 1942 inspection of commercial fertilizers, liming materials, and gypsum are here recorded.

**Commercial fertilizers in 1941-42**, G. S. FRAPS, T. L. OGIER, and S. E. ASBURY (*Texas Sta. Bul.* 619 (1942), pp. 45).—Statistics on fertilizers sold in Texas, information on the fertilizer law, and the analysis of fertilizers are presented in accordance with the fertilizer control law. Other items briefly presented include fillers, non-acid-forming fertilizers, comparison of soft phosphate with colloidal clay and phosphate rock, secondary fertilizing elements, sodium fluorescein as a fertilizer, root stimulants, vitamin B<sub>1</sub>, and fertilizers for water culture.

## AGRICULTURAL BOTANY

**The *Erwinia*-coliform relationship**, R. P. ELROD (*Jour. Bact.*, 44 (1942), No. 4, pp. 433-440).—In this paper the term *Erwinia* is taken to mean the so-called soft-rot group of phytopathogenic bacteria. The manner in which its species ferment lactose would tend to classify them as aberrant forms. On the basis of IMViC patterns the majority appear to approximate *Escherichia freundii*. On the other hand, according to gelatin-liquefying ability, motility, and acid production in glycerol, they seem closer to *Aerobacter cloacae*. Of the cultures tested, 16 were able to macerate vegetable tissues, a character not possessed by any of the 50 coliform cultures. All but 2 of the *Erwinia* isolates fermented pectin in a synthetic medium, while 22 of the 50 coliform organisms, including 3 *Escherichias* of fecal origin, did so. There was no correlation between ability to decompose plant tissue and fermentation of pectin. On the basis of this macerating ability, it is contended that the placing of soft-rot bacteria in a genus (*Erwinia*) separate from the coliforms is valid. At the same time the close relationship of the two groups is recognized.

**Difficulties in defining the genus *Alcaligenes***, H. J. CONN. (N. Y. State Expt. Sta.). (*Jour. Bact.*, 44 (1942), No. 6, p. 721).—An abstract.

**A test for sexual fusion in bacteria**, J. W. GOWEN and R. E. LINCOLN. (Iowa Expt. Sta.). (*Jour. Bact.*, 44 (1942), No. 5, pp. 551-554).—Character differences within a bacterial species furnish the necessary material for such a test. These may be referable, e. g., to white v. yellow colony color, rough v. smooth colony

type, cataphoric movement to + or - poles, or any other character pairs for which it is possible to establish strains giving consistently the same progeny types. Applying the technic to *Phytomonas stewartii*, no evidence of any sexual fusion under the experimental conditions was indicated, but this does not mean that it may not occur in other species or under other conditions. The methods described are believed general enough to facilitate investigation of this problem in any species.

**A simple procedure for the recovery of agar,** G. P. BLUNDELL (*Science*, 97 (1943), No. 2507, p. 76).—The autoclaved used agar is frozen overnight, rapidly melted in warm alcohol, filtered out, washed in distilled water, and dehydrated by washing with alcohol.

**The dehydrogenation of alcohols by streptococci of group B,** I. C. GUN-SALUS and A. J. WOOD. (Cornell Univ.). (*Jour. Bact.*, 44 (1942), No. 5, pp. 523-528).—Resting cell suspensions of *Streptococcus mastitidis* (=agalactiae) were found to oxidize a number of alcohols, several, including certain normal and secondary alcohols, tertiary amyl alcohol, and 2,3-butylene glycol, being more active as H<sub>2</sub> donors to methylene blue than glucose. Methyl alcohol was not activated. Glycerol was dehydrogenated rapidly by some strains. An adaptive mechanism was present in some strains for dehydrogenating certain sugars, as, e. g., galactose. A strain of *Escherichia coli* compared was found to dehydrogenate alcohols very slowly.

**A staining technique for evaluating the toxicity of an antibiotic substance of microbiological origin,** H. KATZNELSON. (Cornell Univ. et al.). (*Canad. Jour. Res.*, 20 (1942), No. 12, Sect. C, pp. 602-608, figs. 2).—Absorption of neutral red by dead cells of *Schizosaccharomyces pombe* is used as an index of the toxicity of an antibiotic agent of bacterial origin.

**Bacteriostatic and bacteriolytic properties of actinomycetes,** M. WELSCH. (N. J. Expt. Stas.). (*Jour. Bact.*, 44 (1942), No. 5, pp. 571-588).—Ability among actinomycetes to dissolve heat-killed gram-negative and gram-positive bacteria was significantly associated with ability to dissolve living gram-positive organisms only, indicating the same lytic principle to be involved in the action on these three substrates. Even sterile filtrates of these actinomycetes possessed similar capabilities, though they were less active against the living gram-positive bacteria. No lytic action was ever observed against living gram-negative organisms. The growth-inhibiting properties of the group appeared to be significantly associated with bacteriolytic action on living gram-positive bacteria. The group of various antibacterial properties recognized in *Actinomyces* G., designated as the "actinomycetin type" of activity, is common among actinomycetes, and this type was found in species of three genera, viz, *Actinomyces*, *Proactinomyces*, and *Micromonospora* and without relation to taxonomic position of antagonist. The significance of the gram-staining properties in relation to susceptibility or resistance of bacteria to the actinomycetin type of activity was demonstrated by examining a large number of strains. No evidence was found for production of adaptive lysins or true lysozyme. There are 36 references.

**An antibacterial substance produced by *Penicillium claviforme*,** E. CHAIN, H. W. FLOREY, M. A. JENNINGS, and D. CALLOW (*Brit. Jour. Expt. Pathol.*, 23 (1942), No. 4, pp. 202-205).—A crystalline substance inhibitory to gram-positive and gram-negative organisms was isolated from the metabolic products of this fungus. Its action is believed to be bactericidal and it is named "claviformin." It proved toxic to animal tissues in concentrations rendering any therapeutic application unlikely, and its action was considerably inhibited by serum.

**Investigation into the production of bacteriostatic substances by fungi.**—**I, Preliminary examination of 100 fungal species**, W. H. WILKINS and G. C. M. HARRIS (*Brit. Jour. Expt. Pathol.*, 23 (1942), No. 4, pp. 166-169).—From the results of this preliminary study it appears that *Aspergillus* spp. are the most promising (about 40 percent positive) of the group investigated, which also included many species of *Penicillium* (about 25 percent positive) and miscellaneous Fungi Imperfecti (mostly negative).

**Mechanics of budding and of conjugation in yeasts**, W. J. NICKERSON (*Jour. Cell. and Compar. Physiol.*, 19 (1942), No. 3, pp. 379-382, figs. 4).

**The relation of yeast multiplication to the composition of apple juice**, H. DICKSON (*Ann. Bot. [London], n. ser.*, 6 (1942), No. 24, pp. 637-644, figs. 7).—Brief descriptions are given of the results of laboratory experiments on the fermentation of apple juice, with special reference to N consumption.

**A taxonomic study of the genus *Hansenula***, C. L. BEDFORD. (Univ. Calif.). (*Mycologia*, 34 (1942), No. 6, pp. 628-649).—A morphologic and taxonomic study (involving new nomenclature) is reported of 100 cultures of yeasts obtained as species of *Hansenula* from various sources in the United States, Europe, Asia, and South Africa. There are 24 references.

**Some additional species of *Ceratostomella* in the United States**, R. W. DAVIDSON. (U. S. D. A.). (*Mycologia*, 34 (1942), No. 6, pp. 650-662, figs. 4).—Three of the five species considered in this taxonomic study are described as new species. There are 23 references.

**Some new and interesting fungi from Mount Shasta**, L. BONAR and W. B. COOKE. (Univ. Calif.). (*Mycologia*, 34 (1942), No. 6, pp. 663-668).—Species of *Pleospora*, *Leptosphaeria*, *Metasphaeria*, *Bifusella*, *Lophodermium*, *Phyllosticta*, *Septoria*, *Ollula*, and *Ramularia* are included.

**A contribution to our knowledge of *Rivea corymbosa*: The narcotic *ololiuqui* of the Aztecs**, R. E. SCHULTES (Cambridge, Mass.: Bot. Mus. Harvard Univ., 1941, pp. [5]+45, [figs. 4]).—The monograph (with 61 references) deals with the history and identification of this drug plant, its nomenclature and taxonomy, its chemical composition and that of related Convolvulaceae, its uses, its vernacular names, and plants confused with it.

**Identification of Japanese maples**, L. CROIZAT (*Amer. Nurseryman*, 76 (1942), No. 9, pp. 5-7, figs. 12).

**The carnivorous plants**, F. E. LLOYD (Waltham, Mass.: Chron. Bot. Co., 1942, pp. XV+352, pls. [39], figs. 11).—The purpose of this monographic work is to give a historical review and summary account of present knowledge about the carnivorous or insectivorous plants. Of these there are about 450 or more species of 15 genera belonging, aside from the fungi, to 6 families. These, with their geographical distribution, are tabulated. The accounts rest in the first instance on studies of actual material collected by the author and received from many other sources. Illustrations are mostly by the author. The principle underlying the arrangement of textual material is the increasing complexity of the traps rather than systematic relationship. Literature references terminate each of the 14 chapters.

**The vegetation of Trumbull County, Ohio**, R. E. SHANKS. (Ohio State Univ.). (*Ohio Jour. Sci.*, 42 (1942), No. 6, pp. 220-236, figs. 3).—A study of the original major forest vegetation types of the glaciated plateau of northeastern Ohio.

**A new perspective in the halophytes**, V. J. CHAPMAN (*Quart. Rev. Biol.*, 17 (1942), No. 4, pp. 291-311, figs. 11).—A critical discussion (41 references) of the more recent papers, with the object of indicating the most profitable lines of future research.

**An ecological and taxonomic study of the algae of British soils.—II, Consideration of the species observed,** F. E. FRITSCH and R. P. JOHN (*Ann. Bot. [London]*, n. ser., 6 (1942), No. 23, pp. 371–395, figs. 8).—New taxonomy is involved, and nine genera are newly recorded for the British Isles. There are 27 references.

**The interaction between thiamine and four fungi,** F. KAVANAGH (*Bul. Torrey Bot. Club*, 69 (1942), No. 9, pp. 669–691, figs. 16).—*Phycomyces blakesleeanus* destroyed thiamin with liberation of pyrimidine and destroyed thiazole. Excess thiazole in a thiamin solution increased growth, but excess pyrimidine did not affect growth. *Phytophthora cinnamomi* apparently utilized thiamin without destroying thiazole or pyrimidine, and growth in a thiamin solution was not affected by the amount of thiazole and pyrimidine therein. *Mucor ramannianus* in a solution containing thiamin alone or with thiazole stopped growth before more than half the latter was removed, and good growth was obtained only in presence of a large amount of thiazole. It synthesized pyrimidine. *Sclerotium rolfsii* in thiamin solutions synthesized considerable amounts of thiazole and under certain conditions apparently destroyed it. It grew much more in the thiamin solution than any of the other fungi. The thiamin requirements of these four fungi were not influenced by the composition of the medium. Destruction of thiazole may not be related to use of thiamin in metabolism but rather to the ability of the fungus to synthesize thiamin from the two intermediates. There are 30 references.

**The effect of vitamin B<sub>1</sub> on the concentration of glucose optimal for the fruiting of certain fungi,** L. E. HAWKER (*Ann. Bot. [London]*, n. ser., 6 (1942), No. 24, pp. 631–636).—In a wide range of fungi, fruiting was found to depend on a balance between the concentrations of carbohydrate (glucose) and vitamin B<sub>1</sub>. In all species examined, including some which fruit freely in the absence of growth substances in the substrate, fruiting fell off if the sugar concentration was increased sufficiently. On the other hand, addition of vitamin B<sub>1</sub> raised both the optimum and maximum concentrations of glucose for fruiting. These data may offer a clue to the interpretation of the role played by vitamin B<sub>1</sub> in the production of fruit bodies by fungi.

**The mechanism of auxin action,** B. COMMONER and D. MAZIA. (Univ. Mo. et al.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 682–685, fig. 1).—From the results of an experiment designed to elucidate the effect of auxin on the salt absorption process in potato tuber slices, it is deemed likely that the effect of auxin on cell enlargement is a consequence of its effect on salt absorption and the water uptake which inevitably accompanies such an increase in sap solute. Auxin stimulates cell enlargement by augmenting the intensity of the osmotic driving force. The dependence of cell enlargement on respiratory processes may be viewed as a consequence of the respiratory dependence of the salt absorption process, and the evidence points to the four-carbon acid metabolism as the respiratory agent particularly related to these phenomena.

**The use of methyl ester of  $\alpha$ -naphthaleneacetic acid for inhibiting sprouting of potato tubers, and an estimate of the amount of chemical retained by tubers,** F. E. DENNY (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 6, pp. 387–403, figs. 4).—Irish Cobbler tubers were placed in bins soon after harvest in the presence of methyl ester-treated paper towels interspersed evenly among them and at the rate of 100 mg. to 1 kg. of potatoes. Sprouting was completely inhibited to the end of the test (October 3 to May 6), though control tubers sprouted freely. Tests with other methods or rates of incorporation of the chemical gave comparable results. The hyponastic response to the methyl ester vapor given by the first well developed leaves at the tips of young potato

plants was used as the basis of a method for estimating the amount of chemical taken up by the tubers from the treatments. In the test above detailed not more than 5 mg. to 1 kg. of tissue were retained, and at least four-fifths of this was in the peel. The flesh of boiled or baked tubers gave negative or very weak tests for the methyl ester, indicating amounts at least lower than 1 mg. to 1 kg. of the cooked flesh. An injury occurred on 5-10 percent of the number of tubers in the chemically treated lots consisting of hard, lumplike excrescences from enlargement of underlying tissue, but no rot developed near them. Germination of treated tubers was reduced, but washing with soap and water or treatments with ethylene chlorohydrin, alone or with sodium thiocyanate or thiourea, improved it. It is believed that the sprout dormancy induced by the methyl ester treatment is more pronounced than that normal for the variety.

**A physiological study of the winter wheat plant** (*Kansas Sta. Bcn. Rpt. 1941-42, p. 30*).—A brief report is given by E. C. Miller.

**Growth rates of maize under field conditions**, R. A. BAIR. (Iowa Expt. Sta. coop. U. S. D. A.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 619-631, figs. 6).—Growth curves obtained by measuring dry weights of four corn varieties weekly during the growing seasons of 1938-39 indicated that they constituted a single population in their percentage responses to the weekly complex of environmental conditions. The dry weight curves were sigmoid, accelerating during the first 40-50 days, increasing uniformly for the next 50-60 days, and dropping off to maturity at 120-130 days. The 1939 plantings were made 2 weeks earlier than in 1938. During the first 50 days after planting the earlier plants developed more slowly and then showed a sharp rise. Vegetative and total growth for the 1939 (early) plantings were superior for all subsequent points on the curves. Weekly dry weight increments, over an 8-week period when the leaf area was about constant, were uniform in 1938 but varied significantly in the cooler, wetter 1939 season. Poor distribution of rainfall apparently accounted for the failure of the dry-weight curve to approximate the growth possibilities represented by the temperature index curve in 1938. There are 15 references.

**An investigation of physiological methods of determining nutrient deficiencies in sugar-cane**, H. EVANS (*Ann. Bot. [London], n. ser.*, 6 (1942), No. 23, pp. 413-436, figs. 9).—This report, having to do with examination of the leaf or stem injection method and the growth increment method, appears to indicate that the first gives but little promise for sugarcane. On the other hand, the growth responses of the crop actually growing in the areas concerned appear to furnish an accurate and reliable technic.

**Hydrogen ion concentration in relation to absorption of inorganic nutrients by higher plants**, D. I. ARNON, W. E. FRATZKE, and C. M. JOHNSON. (Univ. Calif.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 515-524, figs. 2).—Tomato, lettuce, and Bermuda grass plants 5 weeks old and grown under favorable conditions were held for 96 hr. in a series of nutrient solutions ranging at 1 pH steps from pH 3 to 9. Root injury from reaction was apparent only at pH 3 where no absorptions (even suggestions of loss) of Ca and phosphate were evident. For tomato and lettuce this reaction was also wholly unsuited to absorption of other ions tested. Except for phosphate absorption, which exhibited a marked decrease at pH 9, no other untoward effects were noted for this reaction. There was evidence of lower Ca absorption particularly by tomato and lettuce, from strongly acid solutions (pH 4 and 5) than at higher values. No profound effects of external reaction between pH 4 and 9 on the absorption of Mg, K, and nitrate were found.

**Influence of hydrogen ion concentration on the growth of higher plants under controlled conditions**, D. I. ARNON and C. M. JOHNSON. (Univ. Calif.)

(*Plant Physiol.*, 17 (1942), No. 4, pp. 525-539, figs. 4).—The water culture method described and here used for studying the effects of external reaction within the 3-9 pH range provides for maintenance of the same concentration of Ca, Mg, K, nitrate, and phosphate ions and for the availability of Fe and Mn throughout the range. Results indicated that profoundly adverse effects of H- or OH-ion concentration, isolated from other variables, occur only at extremes of acidity or alkalinity. With tomato, lettuce, and Bermuda grass, complete growth failure occurred at pH 3 and a marked decline at pH 9. Within a relatively wide range between pH 4 and 8, fluctuations in H-ion concentration were tolerated by plants, provided an adequate supply of all nutrient elements was maintained. Growth of tomato and lettuce in acid nutrient solutions at pH 4 and 5 was favorably affected by increasing the Ca concentration. At pH 6, however, the growth at low and high Ca concentrations was equally favorable. The external reaction of the nutrient solution had no significant effect on the pH of the expressed sap of either shoots or roots, with the possible exception of extremes unfavorable to growth.

**Plant nutrition and the hydrogen ion.**—III, Soil calcium and the oxalate content of spinach, R. A. SCHROEDER and W. A. ALBRECHT. (*Mo. Expt. Sta. (Bul. Torrey Bot. Club*, 69 (1942), No. 8, pp. 561-568, figs. 4).—As further results of these studies (*E. S. R.*, 88, p. 209), by using the oxalate concentration in spinach as an index of plant performance on soils with increasing Ca under pH 5.2 and 6.8 it was shown that the oxalate concentration in the crop on the acid soil was higher than on the neutral soil and the total in the crop was also higher. When the total oxalate was related to the totals of Ca and Mg it was indicated that on the acid soil the amounts of Ca and Mg taken together were more than the equivalent of the oxalate. With larger additions of Ca to the soil these two basic cations were present in increasing surplus over the oxalate. On the neutral soil the combined amounts of Ca and Mg were not the equivalent of the oxalate except for the soil with the highest Ca application, which gave a spinach crop with excess of oxalate. This raises the question whether this excess may not represent a disturbing condition in the form of Ca deficiency for the plant functions as normal growth.

If the oxalate is considered as removing Ca and Mg out of the reaction in animal digestive processes, these results suggest that Ca as a soil treatment for spinach on an acid soil may provide the crop with Ca and Mg as surpluses over that combined with the oxalate and therefore may contribute some of these minerals of nutritional use. If this soil treatment is applied on a neutral soil, or as a carbonate that should result in neutrality, it is suggested that the crop may possibly be so deficient in bases with respect to its oxalate content that this excess oxalate may not only make the spinach of no nutritional value as a provider of these bases, but may even make it injurious as this excess oxalate disturbs the Ca coming from other food sources. The composition data of the spinach suggest the need for consideration to both the Ca and the Mg supplies, and to the reaction of the soil growing this crop if the fullest values in terms of its content of these nutrient bases are to be realized.

**Effect of cations (K, Na, Ca) on conversion of sugar in plants,** A. KALINKEVICH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 33 (1941), No. 3, pp. 251-253).—From tests in which Ca, K, and Na were supplied to Russian dandelion (*Taraxacum koksaghyz*), it is concluded that Ca favors the accumulation of glucose and Na of fructose, whereas the place of K as regards its action on monosaccharides is between Ca and Na. Sucrose accumulation is favored by Na probably because it promotes the conversion of fructose to glucose and the latter is consumed more rapidly by the process through which sucrose is built up. The

flowering shoots were characterized by a high sugar content, monosaccharides constituting the larger part with glucose predominating. Glucose takes a more active part than fructose in supplying the flowers with sugar.

**Growth responses of barley seedlings in relation to potassium and sodium nutrition,** W. R. and E. MULLISON. (Purdue Univ.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 632-644, figs. 3).—The effects of varying the anions in a nutrient solution where K was replaced by Na differed but little from those effects, already reported (E. S. R., 86, p. 757), under the presence of K. The severe dieback here reported of plants grown without either Na or K proved due to a K deficiency rather than to interrelations of  $\text{PO}_4$  and  $\text{NO}_3$  or of Ca and Mg, or a toxicity of one of them. About 30-40 p. p. m. of K was optimum for growth of young barley seedlings under the test conditions. When both Na and K were absent, K-deficiency symptoms appeared much earlier and more severely than when Na was present. In fact, this was one of the earliest of any deficiencies to appear in barley. In young growth stages Na replaces K to some extent, though it cannot do so entirely. This is especially marked when the amount of K is low. In studies of the effects of K at various nutritional levels Na must be excluded from the nutrient solution to obtain an accurate picture of the role of K in plant metabolism. There are 19 references.

**Studies on the partition of the mineral elements in the cotton plant.**—**III, Mainly concerning nitrogen,** E. PHILLIS and T. G. MASON (*Ann. Bot.* [London], n. ser., 6 (1942), No. 23, pp. 469-485, figs. 6).—Continuing the series (E. S. R., 85, p. 455), the problem of protein regulation in the leaf is considered. From the fact that disks punched from leaves and floated on a nutrient solution containing inorganic N can form protein as readily as intact leaves, it is concluded that protein synthesis is determined by factors in the leaf. In four further experiments under a wide range of conditions it is shown that the protein-N level is largely determined by the crystalloid-N level (dry weight basis). As the latter level is increased, there is a rise in protein-N level to a maximum, after which a further rise in crystalloid-N causes a decline in protein-N. It is pointed out that this type of relation is characteristic of apolar adsorption. Rather limited data on the relation between polysaccharides and total sugars and between insoluble and soluble P suggests that adsorption may also play an important role in determining the levels of polysaccharide and insoluble P, respectively.

**Studies on foliar hydration in the cotton plant, I, II,** T. G. MASON and E. PHILLIS (*Ann. Bot.* [London], n. ser., 6 (1942), No. 23, pp. 443-453, figs. 5; pp. 455-468, figs. 5).—Two papers are presented.

**I. The effects of potassium supply and size of plant.**—An increase in K supply to plants growing in pots filled with sand led to reduced hydration and increase in size of plant, whereas with plants growing in the open in soil an increase in K led to increase in both hydration and size. Further tests with sand in pots under short daylight to ease the water strain indicated that under these conditions increased K was associated with increased size and hydration as in the soil tests above, whereas in controls under normal daylight increased size was associated with decreased hydration as in the first pot test.

**II. Preliminary observations using the disc-culture method.**—It was found that disks punched from leaves and floated on salt solutions may show very large increases in water content, while those floated on water may lose water. This water uptake occurred both on full nutrient solution and on solutions of  $\text{CaCl}_2$ . An estimate of the electrolyte concentration in the sap was obtained from conductivity measurements, whereas an estimate of total solute concentrations was obtained from freezing-point determinations. It was found that water uptake

might occur without any change, or even with a decline in conductivity and in exerted a diphasic action, concentrations of 1 : 10,000 inhibiting and high dilution, exhibited a very close relationship with water uptake. It is suggested that salt increases the hydration capacity of leaf proteins in the same way that the hydration capacity of gelatin is increased by salts in its isoelectric region. It is also noted that salt might affect respiration, and that this might in some way influence the hydration capacity of protoplasm.

**Anthocyanin pattern in Asiatic cottons**, R. A. SLOW and C. P. YU (*Jour. Genet.*, 43 (1942), No. 3, pp. 249-284).—Seven further types of anthocyanin in cotton are described and shown to be controlled by members of an extensive allelomorph system of which 14 members are now known in the cultivated diploid Asiatic species, *Gossypium arboreum* and *G. herbaceum*. All of these new types were found in China, 6 in field material and the seventh as an anomaly in experimental cultures.

**Carbohydrate and nitrogen trends in bluebunch wheatgrass, *Agropyron spicatum*, with special reference to grazing influences**, S. K. McILVANIE. (U. S. D. A.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 540-557, figs. 8).—Analytical data are presented for plants collected at 2-week intervals from snow disappearance to late fall in a fully developed protected bunchgrass area. Available carbohydrate reserves were stored in the lower internodes in percentage amounts nearly equal to root reserves. Peripheral expansion of the bunch resulted partially from shoot and adventitious root production from the lower nodes. The 7-in. height stage coincided with minimum carbohydrates in the roots and minimum C:N ratio in the plant, and this point is considered most vulnerable in the seasonal development of the species. The appearance of the flower stalks marked the beginning of highest total carbohydrate content in the herbage, which was sustained about a month and then declined rapidly during fall curing and secondary growth. A 2-mo. lag in maximum carbohydrate stores occurred in the herbage and roots, with the latter taking place last. Total N content in the roots was depleted in the vegetative stage to 53 percent of that at the formative stage, and a 70-percent depletion of carbohydrates occurred at the normal minimum. Greatest relative amounts of reducing sugars were associated with rapid vegetative growth, of sucrose with differentiation, and of reserve polysaccharides with a brief rest period prior to secondary growth. The maximum total herbage N content occurred at the close of the vegetative stage and declined to about 70 percent (fresh weight) of this value by the time the first flower stalks appeared. Clipping to crown level at 2-week intervals during 8 weeks of the vegetative stage produced the following changes in the clipped as compared with the unclipped plants: 50 percent less total carbohydrates in the roots and 72 percent less in the herbage; 22 percent more total N in the roots and 53 percent less in the herbage; C:N ratios of 1.27 in the roots, and 1.18 in the herbage of the controls, and of 0.57 and of 0.63, respectively, in the clipped plants. Amide N showed no marked difference. There are 22 references.

**Increased irritability in *Nitella* due to guanidine**, W. J. V. OSTERHOUT (*Jour. Gen. Physiol.*, 26 (1942), No. 1, pp. 65-73, figs. 8).—Guanidine applied to *Nitella* may lower the threshold of e. m. f. required to produce electrical stimulation and may give rise to trains of action currents. Its effect thus appears somewhat similar to that noted for animals. Rapid action currents are produced as well as "square topped" action curves and transitional forms. These effects may be due in part to increased protoplasmic conductivity produced by guanidine.

**Influence of sulfanilamide and derivatives on growth of *Lupinus albus***, D. I. MACHT (*Plant Physiol.*, 17 (1942), No. 4, pp. 671-676).—On testing sulf-

anilamide and six of its derivatives, hydroponic solutions containing them exerted a diphasic action, concentrations of 1:10,000 inhibiting and high dilutions of 1:250,000 stimulating root growth. Blood sera of rabbits and man after administration of the sulfa drugs were no more poisonous than normal blood sera and were usually less so. Phytopharmacological examination of such sera affords a convenient method of differentiating true pemphigus from pemphigoid manifestations of the skin produced by the sulfa drugs.

**A method of studying the movement of respiratory gases through waxy coatings**, R. C. NELSON. (Minn. Expt. Sta.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 509-514, figs. 2).—A micro-gas analyzer and a technic for testing permeabilities of waxy coatings to respiratory gases are described, using a cucurbit fruit as test object. Tests of three types of waxy coatings (commercial wax and dry-bright wax emulsions and spermaceti wax) indicated that the permeabilities of the coatings to  $O_2$  and  $CO_2$  were critical in determining the success of the treatment, the ideal in this case being a high permeability to  $O_2$  accompanied by low permeability to  $CO_2$ .

**Day length and crop yields**, M. W. PARKER and H. A. BORTHWICK (*U. S. Dept. Agr., Misc. Pub.* 507 (1942), pp. [2]+22, figs. 15).—In the present emergency and the years ahead, American farmers will be called upon to produce many crops that are new to them, and new crops inevitably bring new production problems. Much waste of effort and invested capital may often be prevented by knowing the areas to which these new crops are adapted. This publication summarizes many of the agricultural applications that have resulted from studies of the influence of day length on plant development and calls attention to the effect of day length on such strategic crops as soybeans, sugar beets, and hemp.

**A comparison of the effects of green light and of red light on the simple-leaf development of intact and decapitated bean plants**, L. H. FLINT and C. F. MORELAND. (La. State Univ.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 677-681, fig. 1).—Grown under green mercury-incited powder tubes and fluorescent lamps, young bean plants gave satisfactory growth accompanied by starch accumulation in the guard cells without a corresponding development in the mesophyll. Under such conditions the development of simple leaves was slightly greater than in red light obtained from indicated sources. After decapitation there was an abrupt reversal of the responses of the simple leaves to green and red light, accompanied by a reactivation of development under red light.

**Improved cytological methods with crystal violet**, C. S. SEMMENS (*Stain Technol.*, 17 (1942), No. 4, pp. 147-148).—The author presents details of a method of making up the dye solution which is claimed to lead to better quality preparations which also appear to be quite fast.

**Cytological methods for Crepis species**, H. A. TORGY. (Univ. Calif.). (*Stain Technol.*, 17 (1942), No. 4, pp. 171-175, figs. 6).

**Progress in the standardization of stains: Orcein and litmus**, H. J. CONN (*Stain Technol.*, 17 (1942), No. 4, pp. 145-146).

**Notes on mounting media**, J. L. MOHR and W. WEHLE. (Univ. Calif.). (*Stain Technol.*, 17 (1942), No. 4, pp. 157-160).—Notes on media in place of the green euparal of Gilson and on a plasticizer with clarite.

## GENETICS

**The handling of chromosomes**, C. D. DARLINGTON and L. F. LA COUR (London: George Allen & Unwin, [1942], pp. 165, pls. 16, figs. 7).—This book aims to cover all the steps in handling chromosomes, "from dissecting the first animal or plant to drawing the last diagram," in order to serve teachers, students, and workers in research. The 12 chapters take up origin, scope, and purpose of chromo-

some work, equipment, living chromosomes, bulk fixation, smears and squashes, paraffin methods, staining and mounting, special treatments, the control of mitosis, the control of fertilization, photography, and describing the results. Appendixes give sources of material and standard solutions. References (over 25 pages) and an author-subject index are included.

**Production of hybrid corn, G. F. SPRAGUE.** (Coop. U. S. D. A.) (*Iowa Sta. Bul.* P48 (1942), pp. 553-582, figs. 18).—The current method of breeding corn, which uses inbred lines and provides complete control of parentage, is described in detail and compared with earlier methods. Comments are made on commercial production of hybrids, improvement of established lines, seed size, use of second generation seed, and on the relative performance records of the older and more recent Iowa Hybrids. Results obtained in the Iowa corn yield test (*E. S. R.*, 87, p. 215) and certification are indicated as criteria of performance and adaptation.

**Inheritance and linkage of factors for resistance to two physiologic races of *Cercospora oryzae* in rice, T. C. RYKER and S. J. P. CHILTON.** (*La. Expt. Sta.*). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 9, pp. 836-840, fig. 1).—Resistance in Blue Rose 41 rice to *C. oryzae* race 1 was found to be conditioned by a single dominant factor and the moderate resistance of Blue Rose to race 2 to another single dominant factor. Close linkage exists between resistance to one race of the fungus and susceptibility to the other. In crosses between Blue Rose and Blue Rose 41, a very few plants were obtained in which the linkage seemed to have been broken.

**Inheritance of mature plant characters in sorghum, induced by radiation, J. R. QUINBY and R. E. KARPER.** (*Tex. Expt. Sta.*). (*Jour. Hered.*, 33 (1942), No. 9, pp. 323-327, figs. 2).—Nine mature plant characters described, not previously found in sorghum and produced by X-radiation, i. e., zebra stripe *zb*, midget *mi*, yellow leap tip *yl*, fired leaf *fl*, mottled leaf, two red leaf, freckled leaf, and a dwarf, have all been found to be inherited as simple recessives, with deficiencies of recessive homozygotes in several cases. A total of 72 recessive mutations, each deleterious in effect and consisting mostly of common seedling chlorophyll-deficient types, were induced. Favorable material in which to detect a progressive mutation was X-rayed, yet no progressive mutations were produced.

**Extent of pathogenicity of hybrids of *Tilletia tritici* and *T. levis*, C. S. HOLTON.** (U. S. D. A. and Wash. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 12, pp. 555-563).—Of 50 interspecies and interracial hybrids of *T. tritici* and *T. levis*, about 83 percent of the former perpetuated themselves as contrasted to only 59 percent of the latter. On the other hand, the race hybrids were more productive of new pathogenic segregates than the species hybrids. Some segregates from the various hybrids proved more virulent than the parent races, others were less so, whereas still others were similar in pathogenicity. Entirely new combinations of pathogenicity factors were produced in several of the hybrids, as indicated by their pathogenicity to the Hussar × Hohenheimer variety, which is highly resistant to all known spontaneously occurring races of the wheat bunt. Pathogenicity in *T. tritici* and *T. levis* is genetically controlled and apparently inherited on a multiple-factor basis, but factors for pathogenicity and spore morphology are inherited independently. The selective influence of the host variety is important in establishing new pathogenic types resulting from hybridization.

**Inheritance and interrelationship of components of quality, cold resistance, and morphological characters in wheat hybrids, W. W. WORZELLA.** (*Ind. Expt. Sta.*). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 11, pp. 501-522,

*figs. 4*).—The inheritance and interrelationship of components of quality, cold resistance, and several morphological characters were studied on 600  $F_2$  and  $F_3$  hybrids and 66 parent rows originating from a triangular cross of American Banner, Trumbull, and Michikof wheats. The mode of inheritance of gluten strength, granulation, carotenoid content, crude protein, kernel weight, test weight, and cold resistance was found to be quantitative and governed by several genetic factors. In hybrids of American Banner  $\times$  Trumbull, gluten strength and protein content appeared to be monogenic in inheritance. Single genetic-factor differences governed the inheritance of glume, coleoptile, and straw color. Highly significant interannual correlation coefficients were obtained for the components of quality studied. Very little, if any, association was indicated between cold resistance and components of quality studied. Gluten strength and granulation were inherited independently of the other components of quality. Kernel weight was correlated positively with test weight and both characters negatively with carotenoid content. Genetic linkage was found between the genes for (1) gluten strength and glume color, (2) protein content and kernel color, and (3) coleoptile color and straw color.

**The inheritance of reaction of Turkey-Florence-1  $\times$  Oro-1 to race 8 of *Tilletia levis*, C. E. CLAASSEN, O. A. VOGEL, and E. F. GAINES.** (Wash. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 8, pp. 687-694, *fig. 1*).—Three crosses consisting of the three possible combinations of Oro-1, (Turkey-Florence)-1, and Sel. 9 of Oro  $\times$  Turkey-Florence were studied for the inheritance of reaction to race 8. The  $F_1$ ,  $F_2$ , and  $F_3$  of all three crosses and six randomly selected  $F_4$  families of (T-F)-1  $\times$  Oro-1 were tested for bunt reaction during the same year under identical environmental conditions. Oro-1 is highly susceptible to L-8 and (T-F)-1 and Sel. 9 are both resistant to L-8. A major and at least one minor factor appeared to account for the segregation of reaction of (T-F)-1  $\times$  Oro-1. These factors for resistance are carried by (T-F)-1. Crosses of Sel. 9 with Oro-1 and (T-F)-1 indicated that Sel. 9 has only the major factor for resistance. The three parents represent three of the four homozygous genotypes possible under the two-factor hypothesis. Two  $F_4$  families appeared to represent the fourth genotype. Segregation of the major factor in conjunction with the minor homozygous resistant factor was apparently attained in an  $F_4$  family. The average percentage class for each of the nine genotypes was calculated from the average percentages of bunt produced by the  $F_2$  plants of the three crosses and by the four homozygous genotypes.

**A hereditary variegation in tomatoes, J. W. and M. M. LESLEY.** (Calif. Citrus Expt. Sta.). (*Genetics*, 27 (1942), No. 5, pp. 550-560, *figs. 5*).—This variegation, characterized by abnormal pale-green areas occurring on normal leaves and green stems and found to be nontransmissible by the methods ordinarily effective with a virus, is believed to be genetic in nature. The variegation behaved as a dominant character and was, as a rule, inherited maternally. In extreme cases, the variegated plants were entirely unfruitful.

**Comparative cytology of sterile intra- and fertile intervarietal tetraploids of *Antirrhinum majus* L., A. H. SPARROW, M. L. RUTTLE, and R. R. NEBEL.** (N. Y. State Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 9, pp. 711-715, *figs. 7*).—A comparison of microsporogenesis and the percentage of unaborted pollen in intra- and intervarietal snapdragon tetraploids, showed that sterility in the intravarietal forms is not correlated with the mean number of chromosome associations, nor with a difference in the mean valency per cell, nor with the valency percentage, nor with group associations.

**Breeding work toward the development of a timber type of blight-resistant chestnut.**—Report for 1941, A. H. GRAVES (*Amer. Jour. Bot.*, 29 (1942), No. 8, pp. 622-626, figs. 3).—This progress report (E. S. R., 87, p. 83) is summarized by the author as follows: "In the  $F_1$  Japanese-American hybrid chestnuts the American parent is incompletely dominant. In order to continue breeding for the desired result, namely, a blight-resistant chestnut of tall erect growth, suitable for a timber tree, the  $F_1$  hybrids are being kept in vigorous condition by a kind of bridge grafting. No definite statement of the genetic situation in the Chinese-American hybrids can yet be made. A situation in the breeding of certain types of tobacco which is similar in some respects to that of the Japanese-American hybrids of chestnut is briefly described. A record of the results of breeding of various chestnut species and hybrids in 1941 is given, including four combinations new to science. It is stated that the possibility of natural variation in the chestnut in the direction of disease resistance should not be ignored, and in this connection a plea is made for native nuts to be sent to the Brooklyn Botanic Garden."

[Abstracts of papers on animal breeding and artificial insemination for presentation at the thirty-fifth annual meetings of the American Society of Animal Production] (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 341-345, 346-347, 348, 349, 351, 358, 358-359, 360).—Brief summaries are presented of papers giving the results of the following studies:

Analysis of a Breeding Program—Growth, Production, and Health, by J. W. Bartlett, S. Margolin, and O. L. Lepard (p. 341) (N. J. Expt. Stas.); Effect of Progeny Testing on Progress From Selection Within Closed Herds, by G. E. Dickerson and L. N. Hazel (p. 342), and Selection for Growth Rate and Productivity in Closed Herds of Swine, by G. E. Dickerson and L. N. Hazel (p. 342) (both U. S. D. A. and Nebr. Sta.); Results to be Expected From Selection on a Family Basis, by J. L. Lush (pp. 342-343), and The Breeding Structure of the Purebred Aberdeen Angus Cattle Population in the United States From 1900 to 1939, by H. H. Stonaker, J. C. Holbert, and J. L. Lush (p. 343) (both Iowa State Col.); Experimental Attempts to Modify the Sex Ratio in Rabbits and Pigs, by H. C. McPhee and O. N. Eaton (p. 343) (U. S. D. A.); Experimental Modification of Estrual Phenomena in Ewes, by E. J. Warwick and L. E. Casida (pp. 343-344), and The Relation of Certain Fundamentals of Sperm Metabolism to the Problem of Semen Storage for Artificial Insemination, by H. A. Lardy and P. H. Phillips (p. 344) (both Univ. Wis.); Fertility in Range Beef Cattle, by A. L. Baker and J. R. Quesenberry (pp. 344-345); Differences in Performance Between Sexes in Offspring of Beef Bulls, by B. Knapp, Jr., and R. W. Phillips (pp. 346-347), and Breeding Methods for the Production of Hybrid Beef Cattle Along the Gulf Coast, by A. O. Rhoad (p. 347) (all U. S. D. A.); The Value of Short-Time Records for Culling and for Progeny Testing of Dairy Cattle, by C. W. Kennedy and D. M. Seath (p. 348) (La. State Univ.); A Dam-Daughter Comparison of Daughters of Holstein-Friesian Sires Proved in D. H. I. A. Work, by R. P. Reece and J. W. Bartlett (p. 349) (N. J. Stas.); A Genetic Analysis of Stakes Winning and Poor Performing Thoroughbreds, by D. G. Steele (p. 351) (Univ. Ky.); The Effect of Sex on the Development of the Pig (E. S. R., 87, p. 657)—III, Differences in Growth Rate Between Males and Females by Lines of Breeding, by R. E. Comstock, L. M. Winters, and J. N. Cummings (p. 358) (Minn. Sta.); Genetic and Environmental Correlations Between the Growth Rates of Pigs at Different Ages, by L. N. Hazel, M. L. Baker, and C. F. Reinmiller (pp. 358-359) (Nebr. Sta. and U. S. D. A.); and The Development of an Inbred Line of Swine From a Crossbred Foundation, by L. M. Winters, R. E. Comstock, and D. L. Dailey (p. 360) (Minn. Sta.).

[**Physiological and genetic studies with livestock by the Bureau of Animal Industry**]. (Partly coop. Mont., Mo., Idaho, and Miss. Expt. Stas.). (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt., 1942, pp. 5, 6, 8-9, 10-11, 12-13, 15, 16-17*).—In continuation of previous studies (*E. S. R., 86, p. 609*), there are included progress reports on investigations of artificial insemination of cattle, sheep, and swine; failure to control sex ratios in rabbits and swine; progeny performance and effects of environment on beef cows; ewes of different breeds for lamb production; index of fleece for selecting breeding sheep; elimination of skin folds and improvement of lamb weight in Rambouillets; inbreeding sheep; record of performance studies with swine breeds; the variance of pig weights and size of pigs in different litters; breeding results with sows; improvement of swine through application of breeding methods; physiology of reproduction studies with mares, stallions, jacks, and jennets; crossing breeds of poultry for egg production; relation of molting and maturity to viability and production in poultry; influence of light on egg production; and mortality and diseases in poultry.

[**Breeding and insemination of livestock by the Georgia Station**] (*Georgia Sta. Rpt. 1942, pp. 45, 49-50, fig. 1*).—There are reported studies of artificial insemination and the transportation of semen for dairy cattle production, the effects of crossing different breeds of rams on native and grade ewes, and sheep breeding for Georgia conditions.

**A new type of recessive achondroplasia in cattle**, P. W. GREGORY, S. W. MEAD, and W. M. REGAN. (*Univ. Calif.*). (*Jour. Hered., 33 (1942), No. 9, pp. 317-322, figs. 2*).—A sublethal type of achondroplasia occurred in Jersey cattle in which inbreeding was practiced. The condition was variable. There was a short, broad head, frequently with cleft palate and other associated abnormalities. In mating of carrier bulls to daughters of heterozygous bulls there were produced 9 defective and 49 normal calves without regard to sex. The defect was inherited as a monofactorial autosomal recessive. Two recessive types of achondroplasia in cattle seem to exist, i. e., the Telemark type and the one herein reported.

**Study of wool quality as the basis of individual selection in breeding of Deccan sheep**, E. J. BRUEN, S. S. KHOT, and A. K. DESHPANDE (*Indian Jour. Vet. Sci. and Anim. Husb., 11 (1941), No. 3, pp. 181-206, pls. 4, figs. 8*).—Four types of wool were sheared from six locations on Deccan sheep. The means and variation of the fibers of each grade were ascertained. Among those tested there were included over 6,000 fibers in the fine and strong groups. The percentages of the different types from the different regions of the fleece are shown, and analysis of variance was included to bring out the effects of different breeds on the grease and density.

**Experimental design for testing inbred lines of swine**, G. E. DICKERSON. (*U. S. D. A.*). (*Jour. Anim. Sci., 1 (1942), No. 4, pp. 326-341, fig. 1*).—A statistical analysis is presented of the variance theoretically expected in crosses between unrelated and related inbred lines. "Additive genetic differences between unrelated inbred lines are expected to average  $\sqrt{2}$  times as large as those between unrelated first generation line crosses, 2 times those between top crosses of unrelated inbred lines, and  $\sqrt{8}$  times those in comparisons of individual top crosses of unrelated lines with outbred stock." The importance of genetic differences in mothering ability in inbred and line crosses is noted. The average number of replications required to give statistical significance to 180-day weights and productivity between two unrelated inbred lines is given for different degrees of inbreeding and varying numbers of sires per line and litters per sire. As the homozygosity of inbred lines increases, average differences between inbred lines

approach a maximum, which is  $\sqrt{2}$  times as large as average genetic differences between unrelated individuals in an outbred population, when all gene effects combine additively. The comparable maxima are 1 for line crosses,  $\sqrt{0.5}$  for top crosses, and 0.5 for comparison of individual top crosses with outbred stock. The differences between groups would increase with nonadditive gene effects and increased inbreeding. Differences between groups were smaller as a result of selection within the groups. The average numbers of animals necessary for statistical significance of expected intraherd and intra-season differences between groups at the U. S. Regional Swine Breeding Laboratory were suggested.

**The individuality of sows in regard to size of litters, C. HALLQVIST** (*Hereditas*, 28 (1942), No. 1-2, pp. 127-135).—The number of pigs alive after 6 weeks proved to be more effective as a means of selection than the number born, but the best results were obtained when due regard was paid to both. The data were based on a variance analysis of litter sizes of total and live pigs at birth and alive at weekly intervals up to 6 weeks in 596 litters produced by 117 sows having 3-10 litters each. The average litter size was 10.6 and was separated into groups above and below this amount, having averages of 11.6 and 6.8 pigs, respectively. There was a difference of 1 in litter size of the latter group which agreed closely with 0.96, which was calculated from the intraclass correlation of 0.20 and the difference between the early litter sizes. By elimination of the sows having less than the average sized first litters, subsequent litter size was increased 0.5 or somewhat less than 5 percent. Further analysis showed that differences were most pronounced in number of pigs born, but consideration of the number alive at 6 weeks proved a helpful addition. Such selection resulted in an increase of 5.8 percent in the litter size and 3.6 percent in the weight of subsequent litters at weaning.

**Inherited macrocytic anaemias in the house mouse. II, Dominance relationships, H. GRÜNERBERG** (*Jour. Genetics*, 43 (1942), No. 3, pp. 285-293).—In further study of the relation of the macrocytic anemia genes  $W$  and  $W^v$  in the mouse (E. S. R., 82, p. 465) it appeared that  $W$  had no measurable effect on the blood of the heterozygote  $W/+$  regardless of the amount of variegation. On the other hand, mice heterozygous or homozygous for  $W^v$  showed reduced numbers of erythrocytes per cubic millimeter of blood.

**Predetermination of sex, J. W. GOWEN and R. H. NELSON.** (Iowa Expt. Sta.). (*Science*, 96 (1942), No. 2503, pp. 558-559).—Genotypes genetically controlled have been established in *Drosophila melanogaster* for sex ratios all males in over 500 matings in eight generations. No failures in finding male-producing genotypes occurred. Means of sex control are thus established.

**The genetics of the grouse locust *Tettigidea parvipennis* Harris, C. M. GOOD, JR.** (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 44 (1941), pp. 234-237).—Known hereditary factors include 19 in the species *T. parvipennis*, including 16 color pattern factors, 1 for long and short wings, a lethal, and a wild type gene. There are 10 factors on one chromosome without crossing over. Genetic factors were located on at least three of the six chromosomes.

**Development of strains of general purpose breeds possessing high egg production and early feathering tendencies, D. C. WARREN** (*Kansas Sta. Bion. Rpt.* 1941-42, p. 47).—The development of strains for early feathering in White and Barred Plymouth Rocks and Rhode Island Reds by crossing with New Hampshires.

**Crosses between inbred lines of the domestic fowl, A. J. G. MAW.** (Iowa Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 548-553).—The method of breeding known as top crossing gave better results than crossing inbred lines with relationship between them. As the relationship between the parents

increased from 0 to 60.5 percent, chick mortality increased and body growth and egg production decreased. The effect of different methods of breeding was ascertained from the progeny of inbreds, single, double, and triple crosses and top crosses with the descendants of inbreds of Waters and Lambert (E. S. R., 75, p. 763) and an English inbred line. Single-Comb White Leghorns served as controls. There were from 76 to 1,290 chicks produced by the different methods of breeding.

**An inherited micromelia in the domestic fowl, V. S. ASMUNDSON.** (Univ. Calif.). (*Jour. Hered.*, 33 (1942), No. 9, pp. 328-330, fig. 1).—In connection with a study of embryos failing to hatch, it was suggested that micromelic embryos were due to a double autosomal recessive effect since in 763 chicks and embryos the abnormalities occurred at the rate of 15 normal to 1 abnormal. Micromelic embryos had much shortened and thickened extremities and deformed beaks. The long bones of micromelic embryos were reduced in weight and were higher in ash than normals. The wing bones of chicks after 22 days' incubation were lower in ash than the leg bones.

**Growth of turkeys.—II, Relative growth of the tarsometatarsus, V. S. ASMUNDSON and I. M. LERNER.** (Univ. Calif.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 505-510, fig. 1).—Continuing this series (E. S. R., 82, p. 668), statistical treatment of body weights and shank length at approximately 4-week intervals up to 32 weeks of age of 12 groups of turkeys comprising three Bronze strains, and five other varieties and crosses between them, indicated that general size factors controlled growth from 4 to 16 weeks of age. At later periods shank length increases were relatively small. Comparatively large broadbreasted Bronze turkeys had relatively shorter legs than smaller strains. Differences in the rate of growth had a greater influence on the proportion of the length of the shank to body weight at 32 weeks of age than differences in the rate of growth of the shank. These conclusions were derived from calculation of constants of heterauxesis and allomorphosis at the different ages (E. S. R., 85, p. 383). Heterauxesis refers to the relation of the rate of growth of the tarsometatarsus and body, whereas allomorphosis refers to the relation between the length of the shank and total body weight.

**A preliminary study of the effect of sunlight, dubbing, and fractionated anterior pituitary extract upon growth, endocrine glands, and sexual capacity of Single Comb White Leghorn cockerels, N. NIKOLAICZUK and W. A. MAW.** (*Poultry Sci.*, 21 (1942), No. 6, pp. 483-496, figs. 2).—The effect of sunlight and dubbing and the influence of a fractionated pituitary extract on growth, weights of the gonads and other endocrines, and spermatogenesis were studied in 8 groups of 10 Single-Comb White Leghorn chicks each. One half had access to sunporches and the other half received no direct sunlight. Two lots in each group were dubbed at 4 weeks of age and 2 lots received the pituitary extract on alternate days from 11 to 30 weeks of age. Half were killed at 23 and the balance at 30 weeks for determination of the weights of the endocrines. Histological study was made of the testes from 1 bird of each lot. Sunlight had no effect on the development of the body size. Thyroid and adrenal weights were reduced and the pituitary and testes weights and breeding potentialities were increased by sunlight. Dubbing retarded early development of the endocrines but stimulated their final development to greater weights than normal. Dubbing caused an early deceleration of growth rate, followed by compensatory development toward maturity so that dubbed birds showed a slightly superior body size at 30 weeks of age, although a slightly inferior spermatozoa count. Injection of pituitary extracts gave no evidence of a modified growth impulse but there was a higher spermatozoa count. Microphotographs of the testes of single birds from each of the lots are presented.

**Time of pigment deposition in brown shelled hen eggs and in turkey eggs,** D. C. WARREN and R. M. CONRAD. (Kans. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 515-520, figs. 3).—Although some of the pigment of brown shelled hens' eggs was being deposited throughout the time of shell formation, it appeared from prematurely expelled eggs that 50-74 percent of the shell pigment was added in the last 5 hr. before oviposition. Turkey eggs acquired the specks at or near the time of laying. The pigment deposited in the shell 3, 6, 9, and 12 hr. after eggshell formation was first detected in the oviduct was ascertained by chemical methods and densitometer readings of photographic plates. In conducting the work the bird was anesthetized with nembutal and the egg expelled by pressure.

**Masculine copulatory behavior in intact and castrated female rats,** F. A. BEACH and P. RASQUIN (*Endocrinology*, 31 (1942), No. 4, pp. 393-409, figs. 5).—Studies of the responses of normal and ovariectomized ♀s to receptive ♀s and ♂s showed that the masculine sexual reactions of the ♀ rat are not dependent on ovarian hormones.

**Oogenesis and its relation to the oestrous cycle in the adult mouse,** W. S. BULLOUGH (*Jour. Endocrinol.*, 3 (1942), No. 2, pp. 141-149, pl. 1, figs. 2).—Study of the number of mitoses in the germinal epithelium of the ovary at different stages of the oestrous cycle in 40 mice showed that mitotic activity was least in dioestrus with gradual rises to reach high levels in the post-ovulation oestrus. Mitoses of the germinal epithelial cells, the meiosis of the primary oocyte, and mitoses of the secondary oocyte all take place in the post-ovulation oestrous period, and it is suggested that their occurrence may be related to a high oestrogen concentration in the region.

**A comparison of the effects of two gonadotropic hormones on immature fowl gonads,** E. H. HERRICK and C. H. LOCKHART. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 44 (1941), pp. 418-419).—Intramuscular injection of Antultrin and Antultrin-S into immature ♀ chicks caused a greater development of ovarian follicles than was found in uninjected controls. There was no significant effect of such treatment on the development of the ♂ gonads.

**Seasonal variation in semen quality of the dairy bull,** R. E. FERR, F. N. ANDREWS, and J. H. HILTON. (Ind. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 815-826, figs. 5).—All factors studied, which included volume, concentration, motility, sperm per ejaculate, sperm survival, and abnormal sperm, showed spring semen to be superior except in pH, which did not vary. The summer ejaculates were poorest and, semen produced during the fall and winter months did not vary significantly from the mean. The study was based on 879 ejaculates from nine bulls representing the four major dairy breeds and variance analysis of semen from four young bulls collected weekly. A bibliography on sperm character and artificial insemination in cattle is presented.

**Relation of mammogenic lobule-alveolar growth factor of the anterior pituitary to other anterior pituitary hormones,** J. P. MIXNER, A. J. BERGMAN, and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 31 (1942), No. 4, pp. 461-466).—Comparative assays of a number of pituitary hormones for the mammogenic growth factor indicated that it was protein in nature but was not identical with the lactogenic, thyrotropic, or gonadotropic hormones. These studies were carried on with ovariectomized ♀ mice (E. S. R., 87, p. 845). Some extracts high in these hormones did not give positive lobule alveolar responses.

**Dilutors for stallion and jack semen,** V. R. BERLINER. (Miss. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 314-319).—A dilutor for jack and stallion semen for use in artificial insemination was prepared by dissolving a ½-oz. gelatin capsule containing 5.76 gm. of glucose and 0.67 gm. of Rochelle salt in

100 cc. of water and adding one egg yolk free from its membrane and other materials. This dilutor produced 90 percent sperm activity after 48 hr. in 30 samples, and 86 percent pregnancies in 22 mares. Such a dilutor should be pasteurized and used at a temperature to avoid shock, and seemed especially good for storage with gradual cooling to about 0° C. (E. S. R., 86, p. 316).

**The hydrogen-ion concentration of the semen of the bull, J. ANDERSON** (*Jour. Agr. Sci. [England]*, 32 (1942), No. 3, pp. 298-307, figs. 5).—The mean pH of 221 ejaculates of semen collected from normal bulls by the use of the artificial vagina was  $6.73 \pm 0.020$ . Individual differences in the variance between 11 bulls were significant. Where there was a higher semen acidity a better motility in storage was maintained. Alkalinity induced a decrease in activity during storage periods.

**Studies in fertility in sheep.—II, Seminal changes affecting fertility in rams, R. M. C. GUNN, R. N. SANDERS, and W. GRANGER** (*Austral. Council Sci. and Indus. Res. Bul.* 184 (1942), pp. 140, pls. 15, figs. 39).—Artificially hot dry atmospheres, to which 10 rams were exposed for varying intervals up to 27 days with daily electrical ejaculations (E. S. R., 75, p. 822), were found to cause seminal degeneration varying in extent with the height of the temperature and the duration of the treatment. When the rams were subjected to temperatures higher and humidity lower than the paddock, degeneration of their semen occurred in all cases in a few days and was progressive at times even after the exposure was discontinued. Several treatments of shorter intervals led to the conclusion that exposures to hot temperatures of different intervals resulted in degeneration of the semen, which corresponded to that observed in rams subjected to hotter and colder districts of Australia. A numerical expression of semen characters based on activity, reaction, and morphology of the sperm is presented. A survey of the conditions of ram semen from different regions showed that seminal degeneration was also associated with conditions causing fever, arsenic dipping, and nutritional deficiencies. It was observed that seminal degeneration occurred about 6 mo. after the greenness of pasture was lost and about 4 weeks after the beginning of the sustained maximum temperature above 90° F. Regeneration was not complete until about 2 mo. after the unfavorable condition ceased.

**Effects of oestrogen (stilboestrol) on the sperm production of adult rams, M. C. CHIANG** (*Jour. Endocrinol.*, 3 (1942), No. 2, pp. 192-202, figs. 4).—Study of semen production by two adult Suffolk rams from which there was absorption of implanted stilboestrol showed that the implants caused a definite increase in sperm production and no decrease in sperm quality, as has been reported for the rat by Ringo.<sup>1</sup> Although ejaculations were studied 71-90 days after the administration of stilboestrol, there was no definite sign of ill effects. Sperm were ejaculated twice each day for from 50 to 100 days by each of the two rams. Study was made of the samples for amount of normal and abnormal sperm and the average reaction time of the rams, as well as the keeping quality and oxygen consumption of the spermatozoa. In two rams there were implanted from 10 to 40 stilboestrol tablets with removal of the remaining material at later dates.

**A study of estrus and ovulation in the mare, J. N. CUMMINGS.** (Mont. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 4, pp. 309-313).—Data in addition to those of Andrews and McKenzie (E. S. R., 86, p. 178) are reported on oestrus and ovulation in 16 mares, all except 2 with foal. In the 40 oestrous periods observed there was an average of 11.31 days from foaling to the first signs of oestrus ascertained with a teaser stallion. Ovulation determined by rectal palpa-

<sup>1</sup> Anat. Rec., 72 (1938), No. 4, Sup., pp. 118-119.

tion occurred an average of 17.8 days after foaling. The average duration of all oestral periods was about 5 days. The length of oestrus and dioestrus, the time of ovulation, or the type of oestrus had little predictive value in succeeding cycles when the observations were based on a single cycle. There was more variation in foaling oestrus than in subsequent oestral periods.

**Hormonal augmentation of fertility in sheep.**—I, **Induction of ovulation, superovulation, and heat in sheep**, J. HAMMOND, JR., J. HAMMOND, and A. S. PARKES (*Jour. Agr. Sci. [England]*, 32 (1942), No. 3, pp. 308-323).—Detailed data are reported on the condition of the ovaries, ova production, and corpora lutea of 112 ewes slaughtered at various intervals following injection with extracts of anterior pituitary, pregnant mare serum, human pregnancy urine, and synthetic gonadotropins during oestrus and anoestrus. Extracts of horse pituitary gland, pregnant mare serum, and pregnant urine produced ovulation in anoestrous sheep, but the number of ova shed was independent of the dosage. Horse pituitary extracts and pregnant mare serum caused sexual receptivity only in animals having regressing corpora lutea. The presence of an active corpus luteum usually suppressed both ovulation and heat, but horse pituitary extract a few days before the corpus luteum was due to regress, caused superovulation at the next heat. The number of ova washed from the vagina of animals slaughtered are reported.

**Isolation of adrenocorticotrophic hormone from sheep pituitaries**, C. H. LI, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Science*, 96 (1942), No. 2498, p. 450).—The methods for separation of adrenotropic hormone from sheep pituitaries are described, including description of two methods of biological standardization based on a repair of the adrenal cortex of the hypophysectomized immature ♀ rat and the maintenance of the adrenal cortex of the hypophysectomized ♂ rat.

**Relation of thyroid to mammary gland structure in the rat with special reference to the male**, J. F. SMITHCORS and S. L. LEONARD. (Cornell Univ.). (*Endocrinology*, 31 (1942), No. 4, pp. 454-460, figs. 11).—Thyroidectomy at 25 days of age of immature normal and castrated ♂ rats caused inhibition of mammary duct growth and stimulation of alveolar development, confirming previous findings (E. S. R., 85, p. 469). It was impossible to tell glands from thyroidectomized animals treated with oestrogen from glands of such animals treated with male hormone.

## FIELD CROPS

[**Field crops research in the Bureau of Plant Industry**]. (Partly coop. State expt. stas. et al.). (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1942, pp. 5-9, 9-10, 12-13, 16-17, 24, 25, 26, 27).—Accomplishments and current results are reported by M. A. McCall, H. W. Barre, O. S. Aamodt, J. R. Magness, E. W. Brandes, and W. W. Garner from breeding work with corn, wheat, oats, rice, grain sorghum, cotton, alfalfa, red clover and sweetclover, soybeans, bromegrass, potatoes, sorgo for sugar and alcohol, sugarcane, and sugar beets. The improved varieties included Comanche and Pawnee, new hard red winter wheats high-yielding and resistant to leaf rust (Pawnee is also moderately resistant to the Great Plains strain of hessian fly); expansion of areas growing Pilot and Rival spring wheats resistant to leaf rust; Pioneer and Wintok winter-resistant oats and Rangler oats resistant to crown rust and smut; disease-resistant rices; new grain sorghums saving harvest labor and resistant to chinch bugs; improved American Egyptian cotton, two new strains of sea-island stapling 1½-1¾ in., and better long-staple upland cottons; A-136, a wilt-resistant alfalfa; Arkan, Magnolia, Boone, and Gibson soybeans; potato varieties

combining resistance to diseases and insects with high yield and good market and cooking quality; C. P. 33/243, a disease-tolerant sugarcane; and U. S. 215×216, an improved leaf spot resistant sugar beet. Improvements in cultural practices were treatment of cottonseed with Spergon replacing mercurial and other chemical dusts and reginning cottonseed to save chemicals and obtain linters; need of more K for cotton in rotation with peanuts and less N in rotation with soybeans; production, harvesting, and retting practices for hemp; practicing a system of deferred and rotation grazing to improve pastures damaged by overgrazing or drought; superiority of crested wheatgrass to native range and other grasses in pasture experiments in the northern Great Plains; mixing artificial cultures with cottonseed meal or sand for inoculation of clovers in the Southeast; satisfactory replacement of superphosphate in potato fertilizers with phosphates prepared without use of sulfuric acid; better sugar beet seed yields from proper spacings; and better crops of tobacco after natural weed fallow. Other research considered waxy starches (replacing tapioca) from corn, sorghum, and other cereals; tests of oats for high vitamin and high chlorophyll foods and feeds; establishment of a manila hemp fiber industry in Central America; plantings of sisal and henequen in Haiti, Cuba, and Mexico; and planting of sorgo in Louisiana for production of high-proof alcohol for explosives.

[Field crops work in Alaska, 1938-41] (*Alaska Stas. Prog. Rpt. 1938-41*, pp. 8-11, 13-14, 21-26, 29-31, 33-36, figs. 3).—Experiments reported on again (E. S. R., 81, p. 362) included breeding work with wheat and barley; variety tests with potatoes, alfalfa, clover, sweetclover, and other forage legumes and grasses; observations on legumes and grasses for winter hardiness; cultural and fertilizer tests with grasses and legumes (E. S. R., 88, p. 43), and potatoes; effects of different fertilizers on chemical constituents of potatoes and of treble superphosphate on their growth and maturity under field conditions; storage tests with potatoes; investigation of the hardiness, growth habit, and seed production and improvement of yellow-flowered alfalfa (*Medicago falcata*); and crop rotations. The average acre yields and production costs of wheat, oats, and barley, and oat-pea hay and silage are also recorded.

[Field crops research by the Georgia Station]. (Partly coop. U. S. D. A. and Ga. Coastal Plain Expt. Sta.). (*Georgia Sta. Rpt. 1942*, pp. 12-23, 29-41, 51-57, 62-63, 69-70, 75-76, 92-93, 94, 98-99, 99-101, 102, figs. 4).—Work with field crops (E. S. R., 86, p. 772) at the station, the Georgia Mountain Substation, and outlying fields included breeding work with cotton, wheat, oats, and peanuts; variety tests with corn, cotton, wheat, soybeans, peanuts, castor-beans, and potatoes; comparative yields of small grains variously fertilized; fertilizer experiments with cotton, corn, oats, barley, wheat, vetch, cowpeas, Austrian Winter peas, Alyceclover, and pastures; regional cotton variety-wilt-tests; sources of P for cotton with and without gypsum; minor elements for cotton limed to different pH levels; nutrition of cotton, comparing ammonium and nitrate N with added trace elements; tests comparing treated and untreated anthracnose-infested cottonseed; planting tests and root knot studies with soybeans; certification work with potatoes; variety, planting, spacing, and curing tests with sweetpotatoes; and pasture research, dealing with fertilizers, limestone, and irrigation for Bermuda-lespedeza pasture production, limestone on clover yields, single v. split applications of N for Bermuda grass and Bermuda grass plant studies concerned with distribution of roots and rhizomes at different soil depths and effects of scarification of Bermuda sod. Additional pasture studies at the Georgia Mountain Substation considered pasture plants, clover varieties, response of upland and bottom land pastures to fertilizers, value of supplemental irrigation, and effects of various treatments on yield and flora changes.

[Field crops research in Kansas, 1941-42]. (Partly coop. U. S. D. A.). (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 14, 17-19, 20-26, 27-28, 30-31, 63-64, 65-66, 66-67, 68).—Results from experiments with field crops and related agronomic studies (E. S. R., 85, p. 40) at the station, substations, and soil and crop experimental fields, reported on by R. W. Hoecker, S. W. Decker, A. B. Erhart, R. I. Throckmorton, F. E. Davidson, C. R. Porter, E. Abmeyer, W. F. Pickett, G. A. Dean, H. H. Laude, L. P. Reitz, E. G. Heyne, E. G. Bayfield, J. W. Zahnley, R. W. Jugenheimer, C. O. Grandfield, K. L. Anderson, A. L. Clapp, J. A. Johnson, Jr., J. C. Frazier, E. C. Miller, A. F. Swanson, A. L. Hallsted, L. E. Wenger, F. L. Timmons, L. C. Aicher, H. J. Haas, J. B. Kuska, E. H. Coles, and T. B. Stinson, included varietal tests with winter wheat, corn and hybrids, oats, barley, grain sorghum, sorgo, flax, soybeans, cowpeas, alfalfa for yield and wilt resistance, sweetclover, and miscellaneous grasses and legumes mixtures; breeding work with corn, wheat, oats, barley, grain sorghum, sorgo, flax, alfalfa, buffalo grass, and pasture grasses; sorghum crosses for waxy endosperm grain; inheritance studies of factors affecting quality of wheat; production tests with castor-bean varieties, perilla, sesame, and safflower; cultural (including planting) experiments with wheat, corn, barley, grain sorghum, and soybeans; storage, fertilizer, and variety experiments with potatoes; crop rotations; basin, ordinary, and contour listing for wheat and milo; fertilizer tests with soybeans, wheat, oats, corn, and sweetclover; vitamin B<sub>1</sub> treatment on corn; studies of heat, light, and drought tolerance in corn, sorghum, and spring wheat; study of the relation between the environment of the wheat crop and growth and yield; alfalfa investigations, including correlation of root reserve storage with other physiological processes, time of cutting, and seed production, and varietal improvement, especially for resistance to wilt and black stem; pasture research, including management of livestock, effects of fertilizers and burning on bluestem pastures, tests with mixtures of cultivated grasses, effects of mowing on buffalo and blue grama stands, winter wheat and Sudan grass as a supplement to native grass for pasture, effects of time and method of seeding upon stands of native grasses, and seed production and germination studies with buffalo grass; weed control studies, including methods of killing bindweed with chlorate and other chemicals, cultivation, smother crops, and other practices, physiological study of bindweed in relation to its control, including development of underground roots and reserves and their modification by cultivation, penetration of herbicides, and seed viability; survey of pricklypear near Hays; and study of the root system of hoary cress.

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 12, pp. 1-2, 7, 8, fig. 1).—Experimentation with field crops is reported in articles entitled Louisiana [Corn] Hybrids Lead in Tests at 7 Locations, but Varieties Not Far Behind (p. 1); Hormone Treatments Showed No Benefit in Tests on Corn, Cotton, and Soybeans, by O. A. Leonard, J. A. Pinckard, J. F. O'Kelly, S. G. Brain, A. S. Ramsey, and J. W. Neely (pp. 2, 7); Delta Trials Result in High Corn Yields by Better Hybrids and Adapted Varieties, by P. W. Gull (p. 8); Hairy Vetch Yield Increased by Use of Lime, Phosphate, by C. D. Hoover (p. 8); and Rate and Analysis of Fertilizer for Maximum of Profit [From Cotton], by R. Coleman (p. 8).

[Field crops research in Montana in wartime]. (Partly coop. U. S. D. A.). (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 12-14, 26-27, 28-29, 31-32, 42-43, 44-46, 50, 51-53, 54, 54-57).—Agronomic research at the station and substations (E. S. R., 84, p. 612) providing contributions useful in wartime and reported on by A. H. Post, W. O. Whitcomb, F. M. Harrington, W. E. Pollinger, D. Hansen, D. V. Kopland, R. M. Williams, and F. S. Willson comprised breeding work with wheat, barley, oats, corn, flax, and grasses; variety tests with corn, wheat,

oats, barley, fiber flax, and miscellaneous forage grasses; trials with mustard; fertilizer trials with potatoes, including tests with B, wheat, and sugar beets; cultural (including planting) tests with crested wheatgrass and other forage grasses, alfalfa, wheat, oats, barley, rye, corn, flax, and potatoes; crop rotations on dry land and under irrigation and variously fertilized; maximum crop-producing capacity of soils; grazing studies with crested wheatgrass, Alta fescue, and alfalfa; seeds mixtures for irrigated pasture; pasturing annual crops with hogs; and regrassing abandoned cropland, and other uses of crested wheatgrass. Research and control activities of the grain inspection laboratory with agricultural seeds, and its grading and protein tests with wheat are also reviewed briefly.

**Effect of vitamin B<sub>1</sub> on field crops grown on several North Carolina soils.** W. W. WOODHOUSE, JR., and H. D. MORRIS. (N. C. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 322-326).—Application of B<sub>1</sub> apparently was not effective in increasing yields of corn and cotton on any of six soils studied, except on extremely poor Durham sandy loam, and its addition to corn and cotton fertilizers in the area is not advised.

**[Field crops experiments in Oregon].** (Partly coop. U. S. D. A.). (*Oregon Sta. Bul.* 401 (1941), pp. 10, 45-47, 48-50, 51-54, 56-58, 59-60, figs. 5).—Progress results and accomplishments are reported on from agronomic studies (E. S. R., 82, p. 325) at the station and substations, including breeding work with wheat, oats, barley, potatoes, and grasses and legumes; crop rotations; effect on nodule bacteria of mixing Ceresan-treated oats with inoculated vetch seed; seed production of grasses, sugar beets, alfalfa, and cover crops; tillage experiments and rotations with wheat; sowing of Fairway crested wheatgrass and tall meadow oatgrass with alfalfa to keep out "cheat" grass; and experiments on control of weeds in grain, Canada thistle, creeping velvet grass, and other noxious weeds. Superior varieties or strains of wheat, barley, oats, corn, alfalfa, clover, vetch, sweetclover, grasses, and potatoes developed or introduced by the station are mentioned.

**[Field crops work in Pennsylvania]** (*Pennsylvania Sta. Bul.* 429 (1942), pp. 10-11, 24-25, 34, figs. 2).—Reports of progress are made from research concerned with tests of corn hybrids and open-pollinated varieties, by C. F. Noll; yield and winter injury tests with alfalfa varieties, breeding work with red clover, and seed production tests with strains of grasses, clovers, and other legumes, all by H. B. Musser; trials of soybean varieties, by C. J. Irvin; tests of blight-resistant potato strains, by W. R. Mills; proper stages for combining wheat, by C. O. Cromer; drying grass seed with a cheap, efficient device employing infrared radiant energy, by J. E. Nicholas; burning red fescue tops to control "silvertop" and control of hot-weather grass disease with chloranil, both by C. C. Wernham; importance of white clover in bluegrass pasture, by J. W. White; and sources of K for cigar-leaf tobacco fertilizers, by O. E. Street.

**[Crops work in Puerto Rico in 1941]** (*Puerto Rico Sta. Rpt.* 1941, pp. 14-15, 17).—Variety tests with sugarcane on two soil types, by A. G. Kevorkian and E. Hernández Medina; a trial of the promising lawngrass Transvaal dogtoothgrass (*Cynodon transvaalensis*), by C. L. Horn; and increase of seed of Seminole soybeans, by W. K. Bailey are reported on briefly.

**[Farm crops and range research]** (*Farm and Home Sci. [Utah Sta.],* 3 (1942), No. 4, pp. 3, 5, 6-7, 8, 10, figs. 6).—Sugar Beet Seed Becoming Important Farm Crop, by W. W. Owens (p. 3), mentions new production methods making sugar beet seed growing profitable in certain areas in Utah. Sugar Beet Research, by E. Carsner (pp. 5, 10) (U. S. D. A.), summarizes current activities in control of curly top by breeding resistant varieties, seed production, plant

cover studies, and physiological and plant food investigations, all with sugar beets. New Segmented Sugar-Beet Seed Promises To Reduce Labor Requirements of This Important Crop (p. 10) comments on a method to enable planting of single seed and minimize labor in thinning. Examples of agrohomeic research with practical application to war emergency problems reviewed include range reseeding (E. S. R., 88, p. 187), pastures on alkali land, economy of pastures, a new wilt-resistant alfalfa variety, and advantages of Velvon barley, Uton oats, a new rust-resistant wheat variety, and corn hybrids found adapted to Utah.

**Grass—the stockman's greatest asset**, H. L. WALSTER (*North Dakota Sta. Bimo. Bul.*, 5 (1942), No. 2, pp. 2-7).—Facts on grassland in North Dakota, derived extensively from research of the station, cover grassland types, composition of native and tame grasses and prairie hay at different growth stages, relation of climate to growth and adaptation, and harmful aspects of overgrazing.

**The grasses of Mauritius and Rodriguez**, C. E. HUBBARD and R. E. VAUGHAN (*London: Waterlow & Sons*, 1940, pp. 128, figs. 16).

**A comparison of used and unused grassland mesas in the Badlands of South Dakota**, F. LARSON and W. WHITMAN. (U. S. D. A. and N. Dak. Expt. Sta.). (*Ecology*, 23 (1942), No. 4, pp. 438-445, figs. 2).—Total protection maintained a mixed-grass type dominated by western wheatgrass and dry-land sedges, while combined mowing and light grazing during 40 yr. produced a short-grass type dominated by blue grama grass. The short-grass type produced the greatest density of vegetative cover, and the mixed-grass type greatest forage yield. Needle-and-thread, not a major dominant on the completely protected mesa, was most abundant on the intermittently used mesa. Mowing and grazing apparently had reduced greatly amounts of this species and of *Carex elcocharis* and *C. pennsylvanica* on the mowed mesa. Forbs and woody plants, negligible on the protected mesa, made up much of the cover on the other mesas. Accelerated soil erosion was not evident, but the mowed mesa lacked the thick plant mulch that was on the two other mesas.

**Improving range conditions for wartime livestock production**, F. G. RENNER and E. A. JOHNSON (*U. S. Dept. Agr., Farmers' Bul.* 1921 (1942), pp. [2]+18, figs. 14).—Range conditions are discussed and illustrated, with descriptions of characteristics of soils and forage by which the ranchers can determine which lands need improvement. Ways to improve range outlined include conservative stocking, use of range according to seasonal growth requirements of forage, better distribution of livestock, and grazing the kind and class of livestock for which the forage and range are best suited.

**A short-cut method for estimating grazing use**, R. H. CANFIELD (*U. S. Dept. Agr., Forest Serv., Southwest. Forest and Range Expt. Sta. Note* 99 (1942), pp. 5, fig. 1).—The method described for estimating grazing use uses a relationship which, for the mixed semidesert grass type on the Santa Rita (Ariz.) Experimental Range, was established as existing between amount of a grass stand grazed to a stubble height of 2 in. or less, amount grazed above a 2-in. stubble height, and the ungrazed complement.

**The effect of boron on seed production of alfalfa**, A. L. GRIZZARD and E. M. MATTHEWS. (Va. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 365-368).—On Cecil sandy loam at Chatham, Va., application of 15 lb. per acre of borax resulted in production of from 82 to 184 lb. of seed per acre, while alfalfa receiving no borax failed to set seed. Increases in hay yields ranging from 280 to 743 lb. per acre also were attributed to use of borax. See also an earlier note (E. S. R., 86, p. 616).

**History of the development and industrial use of barley in North America**, J. G. DICKSON. (Univ. Wis. and U. S. D. A.). (*Amer. Brewer*, 76 (1943). No. 1, pp. 70-71, 104, 106, 108, fig. 1).

**Barley freaks**, M. L. MARTINI and H. V. HARLAN. (U. S. D. A.). (*Jour. Hered.*, 33 (1942), No. 10, pp. 338-343, figs. 3).—Unusual barleys produced in extensive breeding work at the Aberdeen (Idaho) Substation included the types named Grandpa, Fine Stripe, Hoodawn, Multiflorus, Many-noded Dwarf, Mary Dwarf, and Lyallpur and leaf, culm, and rachis variations.

**The loss of nodules from legume roots and its significance**, J. K. WILSON, (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 5, pp. 460-471, figs. 3).—Wild white clover was grown under controlled conditions in the greenhouse to about 4 in. high and clipped periodically to about 0.5 in. high, a procedure probably simulating the maturing physiological conditions of many legumes and corresponding to defoliation received under conditions of good grazing management. Defoliation like shading, drying out of the soil, or maturity of the plant caused some nodules to be shed and subsequently to decay. At the initiation of new growth the starch in the nodules largely disappeared, and if this withdrawal was severe enough the nodules became waterlogged and usually disintegrated. These phenomena might account for the higher N content expressed as percentage of dry weight in old nodules and for much of the increase of N in the nonlegume growing in association with the legume.

**Influence of distribution of rainfall and temperature on corn yields in western Iowa**, E. E. HOUSEMAN and F. E. DAVIS. (U. S. D. A. coop. Iowa State Col.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 12, pp. 533-545, figs. 5).—The analysis covering effects of both rainfall and temperature on corn yield employed yield data, 1924-38, from six widely distributed townships in western Iowa having uniform soil and cultural conditions and containing or adjacent to several weather stations affording suitable weather data. Pooling of data for several locations in lieu of a longer series of observations desirable in Fisher's method of analysis employing rainfall for short intervals seems to have been used successfully. Effects of one additional inch of rain above normal fall for July and August was studied and a regression curve drawn. Regression seemed to be of slight aid in estimating corn yield. Practically none of the variation in corn yield was accounted for by variation in amount or distribution of rainfall. Rainfall in western Iowa usually is near optimum. Yield appeared to be related more closely to temperature than to rainfall.

**Duration of receptiveness in corn silks**, D. F. PETERSON. (Idaho Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 369-371, fig. 1).—Receptiveness of corn silks to pollen, as studied by seed setting, extended longer than 19 days. Seed setting by 1-day-old silks was to the extent of 58 percent and by 2- to 8-day-old silks was rather uniform, averaging 91 percent, with subsequent decline, reaching 8 percent on silks 19 days old.

**An adequate sample of corn plots with reference to moisture and shelling percentages**, G. F. HENRY, E. E. DOWN, and W. D. BATEN. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942) No. 9, pp. 777-781).—An experiment involving 10 varieties was made to determine the number of ears necessary for an adequate sample at harvesttime of a variety for moisture content of grain and for shelling percentage. By use of a formula numbers of ears were found for different replications and varieties. An adequate sample is one such that the standard deviation of its mean will at most equal 5 percent of the grand mean.

**Prehistoric maize from Cañon del Muerto**, E. ANDERSON and F. D. BLANCHARD (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 832-835, figs. 4).—The 222 ears of corn examined resembled in general appearance those now grown by the

Papago and other tribes rather than modern Pueblo corn. Most of the corn had floury endosperm, though a few ears were flinty. Pericarp was either red, colorless, or mosaic ( $P^{rr}$ ,  $P^{mo}$ , or  $p$ ).

**Hemp, a war crop for Iowa.** C. P. WILSIE, E. S. DYAS, and A. G. NORMAN. (Coop. U. S. D. A.). (*Iowa Sta. Bul. P49* (1942), pp. 585-600, figs. 8).—Information on the growing of hemp in Iowa (especially in 15 north-central counties), based extensively on experience with the crop in Wisconsin, deals with the current war needs; soil and fertility requirements; cultural methods and field practices; harvesting, retting, and handling the crop; processing the fiber; contracts for hemp acreage; and landlord-tenant relations in hemp production.

**Seed production by kudzu (*Pueraria thunbergiana*) in the southeastern United States during 1941.** P. TABOR. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, p. 389).—A note.

**Chemical composition and grazing value of Napier grass, *Pennisetum purpureum* Schum., grown under a grazing management practice.** R. E. BLASER, W. G. KIRK, and W. E. STOKES. (Fla. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 2, pp. 167-174, figs. 3).—Napier grass selections of disease-resistant types were established in two areas on Leon, Plummer, and Alachua unproductive sandy soil types, fertilized differently, fenced into five paddocks, and grazed rotationally, 1938-40. The stocking permitted the consumption of most grass blades in from 5 to 8 days, thus allowing 20 or more days between grazings for the grass to recover. The grass as managed for grazing contained more dry matter and protein than grass managed for soilage. The ungrazed residue (primarily stems) was inferior to consumed grass in protein, ash, Ca, P, fat, and fiber but slightly higher in carbohydrates. Highly fertilized grass produced an average of 231 animal days grazing, 369 lb. of beef per acre, and 1.60 lb. of gain daily for the 3 yr. Grass fertilized lightly averaged 155 animal days grazing, 219 lb. of beef, and 1.41 lb. gain daily, 1939-40. Desirability of using plants with uniform genotypes for grazing tests with tall growing grasses was shown. As managed for grazing in these experiments, Napier grass was very palatable and nutritious during the entire season and produced much higher daily gains than other grasses tested in Florida. It appeared especially desirable for fattening paddocks and for supplementary grazing.

**Potash deficiency symptoms in Napiergrass, *Pennisetum purpureum*, G. W. BURTON and C. L. LEFEBVRE.** (U. S. D. A. and Ga. Coastal Plain and Ga. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 372-375, figs. 2).—Formation of irregular brown spots on Napier grass leaves and sometimes "firing" of leaf tips and margins was a reasonably dependable index of K starvation. Very leafy strains developed K-deficiency symptoms earlier and to a greater degree than less leafy types. The high K requirement of Napier grass could be supplied with rather large quantities (200 lb. per acre) of KCl. Severe K-deficiency symptoms have been developed by velvetbeans following Napier grass in rotation.

**Observations on the flowering habits of four *Paspalum* species,** G. W. BURTON. (U. S. D. A. and Ga. Coastal Plain and Ga. Expt. Stas.). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 843-848, figs. 3).—The blooming behavior of Dallis grass (*P. dilatatum*), Vasey grass (*P. urvillei*), Bahia grass (*P. notatum*), and *P. malacophyllum* as related to certain climatological factors is presented.

**[Potato and sweetpotato research]** (*Kans. State Hort. Soc. Bien. Rpt.*, 46 (1940-41), pp. 99-126, 207-223, 229-255, figs. 5).—Papers of interest to specialists include Irish Potato Disease and Insect Control by Breeding Varieties Resistant to Their Attacks, by F. J. Stevenson (pp. 99-107), and Improving Profits on Sweet Potatoes Through Increased Yields and Higher Quality, by V. R. Boswell (pp.

117-126), (both U. S. D. A.); Report on Potato Experimental Work—Irrigation, Varieties, and Fertilizers (pp. 109-115), Progress Report on 1941 Irish Potato Investigations (pp. 207-213), and Distribution of Kansas Potatoes (pp. 235-243), all by S. W. Decker, The Prevention of Ring Rot Infection in Potato Seed Stocks (pp. 219-223), and Prevention of Sweet Potato Diseases (pp. 251-255), both by O. H. Elmer, and Storage Conditions for Kansas Potatoes, by H. R. Fox (pp. 229-234) (all Kans. Expt. Sta.); and The Bacterial Ring Rot Situation in the United States (pp. 215-218), and The Production of Early Irish Potatoes (pp. 245-249), both by C. H. Metzger.

Some cold storage studies of Kansas potatoes, F. L. PARSONS (*Kansas Sta. Bul.* 310 (1942), pp. 18, figs. 4).—In 1939-41, data were obtained on shrinkage and deterioration. Relationships between humidity, temperatures, and evaporation in relation to shrinkage and deterioration also were observed in separate cold-storage rooms.

Storage of potatoes of U. S. No. 1 quality was deemed preferable to storing the lower grades. Deterioration and shrinkage during cold storage were severe where decay and sun damage were among the tuber defects. Since about one-half the total shrinkage of good potatoes in cold storage over a 6-mo. period will occur during the first few weeks, sacks of potatoes should contain from 103 to 106 lb. (depending on the storage period) if the market of 100-lb. sacks of potatoes out of storage is desired. With ideal cold-storage conditions and U. S. No. 1 potatoes, use of closely woven cotton sacks will decrease the weight shrinkage compared with potatoes in burlap or open-mesh sacks. Where quality is uniformly good, shrinkage in weight of washed and clean unwashed potatoes is about the same, whereas washed potatoes of low grade shrink more and deteriorate faster than unwashed potatoes in cold storage. Triumphs shrank slightly less than Cobblers. Ultraviolet ray treatment had no effect on the keeping quality of potatoes with certain common defects.

For best results, potatoes evidently should be placed in cold-storage rooms where circulation of air is enough to prevent condensation of moisture on the tubers after the first week or two of storage. Less shrinkage and minimum deterioration will occur if the relative humidity remains fairly uniform at from 85 to 90 percent. The most satisfactory cold-storage temperatures for potatoes are near 45° F. Temperatures below 40° over a long period may cause changes in flavor.

Cold storage of potatoes may be desirable to avoid selling on a temporarily glutted market, to remove field heat or to condition the tubers to carry satisfactorily to market, and to store for a longer period and to market the potatoes locally through established outlets when potatoes are ordinarily shipped in. See also earlier notes (E. S. R., 86, p. 546; 87, p. 298).

Comparative yields of transplanted and direct sown rice, C. R. ADAIR, H. M. BEACHELL, N. E. JODON, L. L. DAVIS, and J. W. JONES. (U. S. D. A. and Ark., Calif., La., and Tex. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 34 (1942) No. 2, pp. 129-137).—Average yields of Caloro rice, 1937-39, from direct seeding, as practiced in the United States, were significantly higher in Louisiana and California than from transplanting, the Oriental method. Early Prolific also averaged higher from direct seeding than from transplanting in Louisiana, California, and Texas, and so did Arkansas Fortuna in Arkansas and Louisiana. None of the varieties at any of the four rice stations averaged significantly higher when transplanted than when sown direct.

Milkweeds and natural rubber, O. A. STEVENS (*North Dakota Sta. Bimo. Bul.*, 5 (1942), No. 2, pp. 11-15, figs. 4).—A popular discussion of milkweeds (*Asclepias* spp.) and other plants secreting latex or containing rubber, including dogbanes,

*Euphorbia* spp., the chicory group, mulberry family, and such plants as guayule, Colorado rubber plant, and rabbitbrushes.

**Edible soybean—a food crop for Hawaii**, C. G. LENNOX (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 46 (1942), No. 3, pp. 139-158, figs. 7).—Cultural requirements for soybeans for food and forage are outlined, with remarks on the status of the crop, its products, use as food (including recipes), nutritional value of green edible soybeans, varieties, and insect pests and diseases. Acre yields of green shelled beans, in preliminary tests, ranged from 3,650 to 4,450 lb. The crops' response to length of day may be important in choice of varieties. Current recommendations are to plant Hokkaido, Emperor, and Imperial in March and April, and these varieties and Hahto in July and August; Hahto, Sac, and Seaweed in May and June; and Seminole and Giant Speckled in September through February.

**Comparison of the efficiency of single applications with repeated top dressings of nitrogenous fertilizers in increasing the yield of dry matter, nitrogen, and vitamin C (ascorbic acid) of Sudan grass**, F. L. WYND. (Univ. Ill.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 645-651).—The relative efficiencies of ammonium sulfate and phosphate on Brennan fine sandy loam were studied when a given amount was added at seeding time and when part was applied at seedling and the rest as a later top dressing. The first cutting of grass was made at 25 days after planting and the second 11 days later. The greater efficiency per unit of added N for increasing total dry-matter yield was found when all the fertilizer was applied at seeding time, and the phosphate was significantly more efficient than the sulfate. The greater efficiency per unit of added N for increasing the recovery of N by the two cuttings was also obtained with the single application of fertilizer, and here again phosphate was the more efficient material.

As to vitamin C, its total yield became less with increases in dry-matter yield and N recovery by the crop. Here, the greater efficiency per unit of N added was found when part of the fertilizer was applied at seeding and part just after the first cutting, and with the sulfate over the phosphate. A tentative explanation is offered relative to the comparative efficiency of N fertilizers based on their distribution throughout the soil profile and on the depth of the plant root system.

**Plant hormone treatment of sugar beet seed**, S. B. NUCKOLS. (U. S. D. A.). (*Sugar*, 37 (1942), No. 9, pp. 22-23).—Treatments of sugar beet seed with Hormodin "A," thiamin hydrochloride (vitamin B<sub>1</sub>), honey, and with Hormodin powders did not, at the rates used, result in any significant improvement in acre yields of roots, in sucrose percentages, or in acre yields of gross sugar.

**The distribution of mineral elements in the sugar beet as influenced by different preceding crops**, W. E. CARLSON. (Mont. Expt. Sta.). (*Soil Sci.*, 54 (1942), No. 6, pp. 425-437).—Nutrition of sugar beets as influenced by four preceding crops was followed progressively through the growing season at Huntley. Acre yields of clean beets were 17.5 tons on potato ground, 15 after beans, 9.5 after alfalfa, and 8.5 tons on beet ground. The amounts of all minerals usually increased from the first to last samplings. Early rapid adsorption of nutrients by sugar beets after beans and potatoes might account for their superiority as preceding crops. P appeared to be the limiting factor of growth after the four preceding crops. Its deficiency was greatest after beets and alfalfa and least after beans and potatoes. The cation balance in tops and roots was altered by growth of different preceding crops.

**A study of optimum crop length**, R. J. BORDEN and F. C. DENISON (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 46 (1942), No. 3, pp. 119-137, figs.

15).—Monthly growth rates of II 109 sugarcane were influenced differentially by the month of starting the crops. Crops started nearer midyear made a uniform monthly elongation thereafter, whereas winter-started crops showed subsequent seasonal effects appearing as both high and low peaks on growth curves. Rates of growth for stalks of all ages were highest between July and October. Age effects, regardless of seasonal effects, were shown as an almost straight-line reduction in elongation between 8 and 25 mo. Numbers of millable stalks at harvest were not influenced by month of start or age at harvest; average length and weight of stalks were affected by the changing status of stalk population. Crusher juice analyses were influenced by age at harvest, e. g., the P percent increased with an increase in age, and both N and K decreased in concentrations as crops became older at harvest.

The crops started in midseason gave yields superior to those starting earlier or later, regardless of age at harvest. The rate at which cane was produced by plant crops fell off sharply after 22 mo., but ratoons continued to make cane at a uniform rate up to 25 mo. Although cane quality continued to improve with age up to 25 mo., sugar yields followed the trends in cane yields. The optimum age to harvest II 109 evidently was at 22 mo. for plant cane and at 25 mo. for ratoons, regardless of the time of starting the crop.

**The first application of nitrogen**, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 46 (1942), No. 3, pp. 103-104, figs. 2).—Development of an excellent crop of 32-8560 sugarcane in a 4-mo. period on a low-N Makiki soil during the best growing weather of the year from application of 40 lb. of N per acre suggested that a much larger initial amount is probably excessive and may be used inefficiently by the crop. See also earlier notes (E. S. R., 87, p. 218).

**Sugar cane investigations in progress at the agricultural experiment station of the University of Puerto Rico**, J. A. B. NOLLA (*Asoc. Téc. Azucareros Cuba, Proc. Ann. Mtg.*, 15 (1941), pp. 31-37).

**The time and rate of nutrient absorption by flue-cured tobacco**, A. L. GRIZZARD, H. R. DAVIES, and L. R. KANGAS. (Va. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 327-339, fig. 1).—In experiments with flue-cured tobacco (E. S. R., 85, p. 616) at Chatham, Va., in 1939 and 1940, differences in crop yield and value per acre due to different fertilizer treatments usually were of doubtful significance. Improvement in yield and value occurred when one-half of the K was withheld and used as a side dressing 21 days after setting out the plants. Absorption of plant food and development of tobacco proceeded slowly during early growth stages (0-35 days) after transplanting, in contrast to the very rapid rates during later periods (36-63 days); N absorption was relatively low during the last interval of growth (50-63 days), while absorption of the other nutrients was high. This emphasized the importance of having available during the latter part of the growing season plenty of nutrients, except N, which should be low during the last 2 weeks. Nutrients contained in the sap, absorption of nutrients per acre by the crop, and chemical composition of leaves and stalks are tabulated for transplants and for growth intervals of 0-21 days, 22-35, 36-49, and 50-63 days.

**Quality characteristics of hard red winter wheat varieties grown in cooperative plot and nursery experiments in the hard red winter wheat region in 1940**, M. A. BARMORE, K. F. FINNEY, and M. E. MCCLUGGAGE. (Coop. Kans. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant Indus.*, 1942, pp. [1]+31, figs. 11).—Quality characteristics of plot and nursery samples of wheat varieties grown in 1940 in cooperation with State experiment stations, as determined in milling,

chemical, and baking studies, are tabulated and discussed, together with averages for the 1938-40 crop nursery samples. Brief reports are also made on special research on the pearling test, micromilling and baking, bromate response and requirement, mixing time, protein content and loaf volume, loaf volume at abnormal protein levels, viscosity as a measure of hard wheat quality, and colloidal investigations.

**Quality studies of wheat varieties grown in the Western region in 1941.** C. C. FIFIELD, H. C. FELLOWS, T. F. HARTSING, R. WEAVER, J. F. HAYES, E. HOFFECKER, and B. E. ROTHGER (*U. S. Dept. Agr., Bur. Plant Indus. and Agr. Market. Admin., 1942, pp. 17*).—Milling, baking, physical, and chemical characteristics were determined on about 90 samples of wheat varieties grown at experiment stations in 1941 and on 9 composite samples representing each of the principal grades of white wheat received on 3 commercial markets. The spring wheats with hard texture, e. g., Marquis, Merit, and White Federation, were generally lowest in acre yield and highest in protein content. The carotenoid content of grain was high for all club varieties except Elgin. Varieties of other classes usually high are Onas, Federation, and Rex. Excellent yellow loaf cakes were made from all varieties with a high particle size index, including Irwin Dicklow, Lemhi, Federation, Onas, Buart, Rex, Hymar, and Triplet. Varieties consistently making good cookies have all had medium to high pearling indices. The best bread, in general, was made from hard red spring and certain white varieties, including Marquis, Merit, White Federation, Baart, and Idaed. Among winter wheats, the hard red winter and the white wheats—Rex, Kharkof, and Turkey selection (C. I. 11530)—made the best bread.

**North Dakota wheat quality in 1942:** Some preliminary observations on several hard red spring wheat varieties, R. H. HARRIS (*North Dakota Sta. Bimo. Bul., 5 (1942), No. 2, pp. 26-27*).—Hard red spring wheats produced at the different substations in North Dakota in 1942 have been high in test weight and vitreous kernel content, kernels plump and well-filled, and the grades excellent because of high bushel weight and absence of visible damage. Wheats examined in 1942 are distinctly higher in test weight, flour yield, and wheat protein content than 1941 samples of the same varieties grown at Edgeley and Fargo. Varietal differences are mentioned.

**Nut grass eradication studies.**—III, The control of nut grass, *Cyperus rotundus* L., on several soil types by tillage, E. V. SMITH and E. L. MAYTON. (Ala. Expt. Sta.). (*Jour. Amer. Soc. Agron., 34 (1942), No. 2, pp. 151-159*).—Cooperative tillage experiments on 10 soil types, 1938 and 1939, showed that nutgrass (*E. S. R., 79, p. 190*) can be nearly eradicated from soils ranging in texture from sandy loam to plastic clay by plowing at 3-week intervals during two successive growing seasons. If a clean-cultivated crop is planted the next year and the few remaining tubers removed as they sprout, eradication will be complete. Results comparable to those with a turn plow followed plowing with a scrape (sweep) or a tractor disk, while a light, horse-drawn disk was unsatisfactory. Unsatisfactory results on an area of low, poorly drained clay indicated that tillage methods should not be used for nutgrass control on areas likely to remain wet long.

**Ecological aspects of the pricklypear problem in eastern Colorado and Wyoming.** G. T. TURNER and D. F. COSTELLO. (U. S. D. A. coop. Colo. State Col.) (*Ecology, 23 (1942), No. 4, pp. 419-426, figs. 5*).—The distribution, characteristics, reproduction, and growth adaptations of pricklypear (*E. S. R., 86, p. 325*), and its reaction to drought, insects, rodents, soil drifting, and grazing are described from extensive studies in the region.

## HORTICULTURE

[**Horticultural investigations by the Bureau of Plant Industry**] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1942, pp. 10-11, 14-16, 17, 19-21*).—Included are progress reports on investigations under the direction of D. M. Crooks, J. R. Magness, B. Y. Morrison, and E. W. Brandes dealing with the production of drug plants, the use of castor oil to replace tung oil, the production of substitute tanning plants, the growing of dry-land gardens, nitrogen requirements of apple trees, new spray materials for control of apple scab, development of new peach varieties, the relation of K deficiency to composition of oranges, the breeding of chestnuts resistant to blight, production of healthy tomato plants for northern shipment, the breeding of lettuce varieties, carbon dioxide treatment of cherries for shipment, importation of strategic plant materials, identification of plant materials, the use of sphagnum moss for growing seedlings, selection and propagation of high-yielding resistant strains of the hevea rubber tree, and the testing of various plants as potential sources of rubber.

[**Horticultural investigations in the Southern States**] (*Assoc. South. Agr. Workers Proc., 43 (1942), pp. 171-173, 174, 175-181*).—Abstracts of the following papers are listed in these proceedings: Genetics of Cultivated Cucumber, by C. F. Poole (pp. 171-172) (U. S. D. A.); Breeding Cucumbers and Muskmelons for the South, by J. M. Jenkins, Jr. (p. 172), and The Effect of the Number of Plants Per Hill and Hill-Spacing on the Fruiting Behavior of the Cantaloupe, by O. B. Garrison (pp. 172-173) (both S. C. Expt. Sta.); Preliminary Results Obtained in the Use of Phosphorus as Compared With Other Fertilizers With Tung Trees, by S. R. Greer (p. 174) (Miss. Sta.); The Use of a Mist Spray in Rooting *Rubus* Single-Bud Stem Cuttings, by S. H. Yarnell and H. T. Blackhurst (p. 175) (Tex. Sta.); Root and Shoot Production by Young Pecan Trees Treated With Indole-Butyric Acid at the Time of Transplanting, by A. C. Gossard (p. 175) (U. S. D. A.); Peach Cultural Tests, Including Sods and Clean Culture, by A. J. Olney and W. D. Armstrong (p. 176) (Ky. Sta.); Breeding Strawberries for the South, by J. C. Miller (p. 177) (La. Sta.); Nutrition of Strawberries in the Upper South, by M. M. Parker (pp. 177-178) (Va. Truck Sta.); Breeding Raspberries for the South, by B. D. Drain (p. 178) (Tenn. Sta.); Results of Breeding Work With the Muscadine Grape, by E. F. Savage (p. 179) (Ga. Sta.); Vitamin C Content of Snap Beans and Cabbage, by B. L. Wade and C. F. Poole (pp. 180-181) (U. S. D. A.); and The Vitamin Content of Peaches, by L. O. Van Blaricom (p. 181) (S. C. Sta.).

[**Horticultural studies by the Georgia Station**]. (Partly coop. U. S. D. A.). (*Georgia Sta. Rpt. 1942, pp. 41, 74, 77, 93-94, 94-98, 99*).—Reports are presented on the breeding of a new sweet corn—Cherokee; breeding watermelons for wilt resistance; breeding tomatoes for resistance to nematodes, *Fusarium* wilt, and *Scotoria* leaf spot; storage of fruits and vegetables; collard breeding; transplanting solutions for pimiento pepper plants; variety tests with snap beans and garden peas; dahlia variety trials; peach fertilizer tests; cover crops for peach orchards; growth and distribution of peach roots; effect of pruning on peach root development; testing of peach varieties; the use of preharvest chemicals on the peach; sawdust mulch for strawberries; tests of strawberry and raspberry varieties; effect of fertilizer on strawberry yields; and culture of the blueberry.

Studies reported from the Mountain Substation include lettuce and garden pea trials, tests of herbs, and the use of overhead irrigation on vegetables.

[**Horticultural investigations by the Kansas Station**] (*Kansas Sta. Bcn. Rpt. 1941-42, pp. 19-20, 31-34*).—Included are comments on the progress of

studies by E. Abmeyer, R. I. Throckmorton, W. F. Pickett, G. A. Dean, R. J. Barnett, G. A. Flinger, S. W. Decker, C. J. Birkeland, and L. R. Quinlan on the cultural needs of apple trees, the use of lime-sulfur for control of apple scab, the use of preharvest sprays to delay drop of apples, the mulching of strawberries, the effect of wax emulsions on newly transplanted conifers, the selection of cold-resistant French crab seedlings, relation of orchard site and mulch treatment to winter injury, testing new varieties of tree fruits, electrolytic resistance as a measure of hardness in brambles, variety tests of vegetables, gas injury of greenhouse plants, relation of leaf structure to rate of photosynthesis in fruit trees, variety tests of herbaceous perennials, and the effects of the November 1940 freeze on trees and shrubs.

[**Horticultural studies by the Montana Station**]. (Partly coop. U. S. D. A.). (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 32-33, 43-44, 54).—Included are brief progress reports on the culture of the tomato, onion, cucumber, and squash, the use of commercial fertilizers for vegetables and fruits, and tomato and sweet corn varieties for Montana, all by F. M. Harrington; boric acid for apples and cherries, the value of leguminous cover crops for sweet cherry trees, and the desirability of limiting the period of clean cultivation in the cherry orchard, all by W. E. Pollinger; and the testing of trees and shrubs for shelterbelt uses, and methods of transplanting shelterbelt seedlings to increase survival, both by R. M. Williams.

[**Horticultural studies by the Oregon Station**]. (Partly coop. U. S. D. A.). (*Oregon Sta. Bul. 401 (1941)*, pp. 35-36, 39, 42-43, 54, 55, 62, 66-67, figs. 3).—Information is presented on studies of the effect of ethylene on the ripening of fruit, pollination of the pear, naphthaleneacetic acid to prevent fruit drop, the relation of pruning to pear production under differential soil moisture treatments, variety tests with blackberries, culture of the hop (including a labor schedule), variety trials with vegetables, the effect of boron on certain vegetables, the storage of rose plants, and the balling of nursery stocks.

[**Horticultural studies by the Pennsylvania Station**] (*Pennsylvania Sta. Bul. 429 (1942)*, pp. 17-19, 23, 35-37, figs. 2).—Included are reports on various studies, by C. O. Dunbar, W. S. Clarke, Jr., R. D. Anthony, F. G. Merkle, E. C. Dunkle, W. R. Whitacre, F. N. Fagan, W. S. Beach, E. M. Rahn, C. E. Myers, J. W. Sindon, G. J. Stout, and C. A. Thomas, on the use of Ladino clover and other plant materials as orchard cover crops, the relation between orchard cover sites and low-temperature injuries, sources of N for the orchard, the need of phosphorus and potash to maintain cover crop growth, the harmful effects of continuous cultivation in the apple orchard, the need of wise use of fertilizer in the orchard during the emergency, the harmful effect of bruising on the condition of apples, the beneficial effect of drying soil on the control of damping-off injury to seedlings, the testing of vegetable varieties including the Penn State Ballhead cabbage and Pennheart tomato, the composting of manure for mushroom culture, the possibility of overirrigating vegetables growing on heavy soil, the value of starter solutions in tomato production, and the fumigation of greenhouse beds to control symphylids.

[**Horticultural studies by the Puerto Rico Station**] (*Puerto Rico Sta. Rpt. 1941*, pp. 3-5, 7, 10, 11-14, 15-17, 18).—Information is given on the progress of studies on the culture, pollination, and breeding of vanilla plants, by A. G. Kevorkian and E. Hernández Medina; varieties of coffee (coop. P. R. Univ. Sta.), by J. Guiscafré Arrillaga and L. A. Gómez; the culture of *Cinchona*, by Kevorkian; the growing of ginger and other miscellaneous spice crops, including nutmeg, Ceylon and Malaya cinnamon, tonka-beans, and black pepper, by C. Alemar, Jr., and W. Pennock; the propagation (by A. Lee and A. Arroyo)

and utilization (by J. K. Alvis) of bamboo for fishing rods; the culture of head lettuce and the production of cantaloup and lima bean seeds, both by W. K. Bailey; the culture and physiology of rotenone-producing crops such as *Derris elliptica* and *Lonchocarpus nicou*, by R. H. Moore and M. A. Jones; and the testing and propagation of newly introduced plants and the occurrence of polyembryony in the mango, both by C. L. Horn.

**Early gardens best started during winter**, L. R. FARISH (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 12, pp. 1, 8).—Late fall or early winter was found to be a favorable season for plowing and preparing the soil for early vegetable gardens. Some of the more hardy species may be planted in January and February in Mississippi. The details of operations are discussed.

**Asparagus production**, H. C. THOMPSON (*New York: Orange Judd Pub. Co.*, 1942, pp. 124, figs. 12).—This book was prepared by a member of the staff of the [New York] Cornell Experiment Station and presents up-to-date information on the principles and practices of asparagus production.

**A study of the time of development of the fibrous sheath in the sidewall of edible snap bean pods with respect to quality**, F. C. STARK, JR., and C. H. MAHONEY. (Md. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 353-359, figs. 2).—Histological studies of Giant Stringless Green Pod and Bountiful bean pods indicated that the tissue, which has been termed the fiber of the side wall and parchment, is actually the mesocarp. The tissue begins as a one-celled layer of parenchyma and later develops into a region of several cells in thickness. An increase in width of the inner mesocarp occurs in a constant proportion for both varieties until the pods attain the No. 5 sieve size. Cool temperatures and high rainfall had a depressing effect on increased cell wall thickness. The thickening of the cell walls of the inner mesocarp in pods grown in 1940 was entirely hemicellulose, with no lignin found.

**The effect of storage on the betanin and sucrose content of garden beets (*Beta vulgaris*) and its importance in a breeding program with this crop**, L. C. CURTIS. (Conn. [New Haven] Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 370-374, figs. 2).—Analyses of beet roots grown from seed sown July 26 and harvested September 30 and then placed in storage at 35°, 40°, and 50° F. showed an increase in sucrose and a decrease in betanin during the first 2 weeks. Roots from seed sown April 29 and dug on July 15 showed no such initial increase in sucrose but rather a gradual decrease up to 21 weeks when there was an appreciable decline. There was a significant increase in betanin at the end of 2 and 6 weeks, followed by a drop at the twelfth week. It is suggested that plant breeders might easily be deceived as to the potential value of their beet stocks unless analyses are made at a definite stage, preferably immediately after harvest.

**The effect of manures, nitrogen compounds, and growth-promoting substances on the production of branched roots of carrots**, G. J. RALEIGH. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 347-352, figs. 2).—Cow or horse urine applied with complete nutrient solutions to carrots growing in sand so as to supply 1 percent or more of urine caused marked branching of the roots. Manures that contained no urine had relatively little effect. Urea, ammonium hydroxide, and ammonium carbonate all caused branching that could not be distinguished from that caused by urine. A number of growth-promoting substances used in varying dilutions did not produce typical branching. In the field, chicken manure, cow manure containing urine, and horse manure containing urine caused some branching of the roots, but the results were variable and not conclusive. In greenhouse experiments a mixture of cow manure and cow urine caused branching of soil-grown carrots.

**Effect of temperature and photoperiod on seedstalk development in carrots**, EL SAYED SAKR and H. C. THOMPSON. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 343-346).—French Forcing carrots sown June 27 and dug October 1 were potted and placed in different temperatures and light durations. All plants that were subjected to 40°–50° F. for 15, 30, 45, or 60 days developed seedstalks or flower buds when grown later at 60°–70° under normal day length. Check plants which did not receive any low-temperature treatment did not develop flower primordia when grown at 70°–80°. The normal length of day was slightly more favorable for flower bud formation than was continuous light. It is conceded that length of day is not a very important factor in the initiation of flowering in the carrot. Where carrots were placed in storage at 35°, 40°, and 50°, subsequently potted, and placed in the greenhouse at 50°–60°, 60°–70°, and 70°–80°, the best results as to flowering were obtained in the lots grown at 50°–60°. Preliminary storage at 40° was more favorable than either 35° or 50°, and 50° was better than 35°.

**Some effects of calcium and nitrogen upon peas**, R. A. SCHROEDER. (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 375-377).—Peas of the Little Marvel variety, grown in 1-gal. jars filled with subsoil of the Putman silt loam series modified with quartz sand to improve the texture, were supplied with different amounts of calcium and nitrogen along with an otherwise adequate nutrient solution. Nodulation was increased as the exchangeable calcium was increased up to 12 milliequivalents at both levels of nitrogen used. However, at each calcium level there was a significant increase in the number of nodules produced at the higher nitrogen level. Dry weights of the peas were increased significantly by inoculation in all except one treatment.

**The effect of inoculation on maturity of canning peas in New York State**, A. W. HOFER and J. K. WILSON. (N. Y. State Expt. Sta. and Col. Agr.). (*Soil Sci. Soc. Amer. Proc.*, 6 (1941), pp. 183-186).—Under New York conditions inoculated strips of peas may mature earlier, later, or at the same time as uninoculated strips. There is no marked tendency toward delayed maturity of inoculated peas in New York as has been reported elsewhere, and no factors have been found which will correlate with the earliness or lateness of the inoculated plats as compared with the controls. The only possibility is that on fields where inoculation produces a distinct yield response there may be a greater tendency toward delayed maturity of inoculated peas. The failure of inoculation to delay maturity in New York may possibly be explained, in part, by the fact that the pea nodule organism seems to be well distributed in the soils of the State, so that the effects of inoculation might well be less striking than in soils where the pea nodule bacteria do not occur naturally in such large numbers.

[Studies with canning peas in Alaska] (*Alaska Stas. Prog. Rpt.* 1938-41, pp. 26-29).—Included are the results of studies of fertilizer requirements and on the rates of seeding.

**A chemical test for pungency in peppers**, S. V. TING and K. C. BARRONS. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 504-508, fig. 1; *abs. in Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, p. 179).—Taste tests for pungency in peppers were found unsatisfactory. A chemical test was devised in which a sample of the dried and ground fruit was treated with ether to extract the pungent principle, capsaicin, and the extract in turn was treated with a 1-percent solution of vanadium oxytrichloride in carbon tetrachloride until no further color change occurred. Sweet pepper extracts showed no green color reaction, while pungent peppers varied from a greenish yellow to a dark green as the content of capsaicin increased.

**Propagation of sage by cuttings**, W. L. DOBAN and A. M. DAVIS. (Mass. Expt. Sta.). (*Amer. Nurseryman*, 76 (1942), No. 5, p. 12).—Cuttings taken in winter rooted well without treatment if inserted in sand-peat or even in sandy soil. Rooting was hastened and somewhat improved if the bases of the cuttings were immersed for 24 hr. in dilutions of naphthaleneacetic or indolebutyric acid before placement in the sand-peat mixture. No bottom heat was provided, but the night temperature of the air was held at about 70° F.

**Further studies on the effect of topping young tomato plants on fruit set and yield**, K. C. WESTOVER. (W. Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 285-288, fig. 1).—This continuation of an earlier study (E. S. R., 87, p. 223) showed that pinching the main stem above the second leaf node about 2 weeks before the plants were set in the field reduced the early yields of the Early Baltimore and Marvelous varieties. As the season advanced, the yield differences decreased and lacked significance. Plants widely spaced in the flats or by potting were more productive than closely spaced ones.

**Deciduous orchards**, W. H. CHANDLER (*Philadelphia: Lea & Febiger*, 1942, pp. 438, figs. 109).—Prepared by a member of the staff of the California Experiment Station, this text discusses fruit production from the basis of research findings of workers in various fields.

**A preliminary study of the manganese content of the leaves of some deciduous fruit trees**, E. EPSTEIN and O. LILLELAND. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 11-18, fig. 1).—A chlorosis of peach leaves, identified as a manganese deficiency, was found to be associated usually with a manganese content in the leaves of less than 17 p. p. m. The range in Elberta peach leaves in June and July was from 6 to 293 p. p. m., suggesting a high luxury consumption of manganese in certain orchards. Changes in Mn content were not large throughout the summer, indicating that samples taken from June to October may be used to reflect the general Mn level. There was found in July 494, 246, 96, 81, 73, 66, 63, and 63 p. p. m. of Mn, respectively, in filbert, walnut, almond, apple, prune, peach, pear, and cherry leaves collected on a single soil. Analyses of chlorotic leaves of six species from various soils gave values from 5 to 25 p. p. m., indicating no differences which could be correlated with the species.

**The phosphate nutrition of fruit trees, III, IV.** (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 1-7, fig. 1; 41 (1942), pp. 1-10).—This series is continued (E. S. R., 84, p. 475).

III. *Comparison of fruit tree and field crop responses on a phosphate deficient soil*, O. Lilleland, J. G. Brown, and J. P. Conrad.—Evidence is presented to show that fruit trees established in Aiken clay loam at Paradise, Calif., did not respond to phosphate applications, whereas 18 annual crops failed to make satisfactory growth on the same soil unless phosphate was supplied. As determined by chemical and biological tests, the soil was extremely low in available phosphorus. The results demonstrated that the phosphate responses of annual plants cannot serve as criteria of the phosphate needs of fruit trees.

IV. *The phosphate content of peach leaves from 130 orchards in California and some factors which may influence it*, O. Lilleland and J. G. Brown.—Data are presented on the results of phosphorus determinations upon leaves collected from 130 orchards, including trees on the above-mentioned Aiken clay loam. The percentage of phosphorus in the dry matter of the leaves decreased rapidly during spring and early summer, followed by a period of minimum seasonal change until the leaves turned yellow in autumn. Variations were recorded between adjacent trees, and a greater variability was associated with trees having the higher analyses. Trees making good growth on a soil that was low in available phosphorus

had a phosphorus leaf content approximating that in many of the better orchards on the more fertile soils. Poor growth could be associated frequently with high phosphorus, and conversely many of the best orchards had a low phosphorus content.

**The relative yields of border fruit trees, E. L. PROEBSTING.** (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 34-36).—Border trees in peach, pear, and apricot orchards do not necessarily outyield interior trees, particularly in orchards planted with adequate distance between trees and receiving good cultural care.

**Statistical analyses of the fertilizer data from the Von Osten apple orchard, E. L. OVERHOLSER, F. L. OVERLEY, J. C. WILCOX, and D. F. ALMENDINGER.** (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 19-22).—In this Wenatchee orchard tree growth, as measured by increases in trunk girth and in terminal growth, was not affected by applications of phosphorus. Nitrogen had a significant positive effect on tree growth, while potassium actually decreased growth. Nitrogen was the only element to increase yields significantly, largely by increasing the number of fruits. Applications of nitrogen alone or with phosphorus or potassium or with both decreased the red color of the fruits, but the loss was more than compensated for by increased production.

**The use of metaphosphate in nutrient solutions, L. J. EDGERTON.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 237-239, fig. 1).—The possibility of using sodium metaphosphate in nutrient solutions buffered at high pH to maintain iron and other constituents in solution was shown in a study in which apple seedlings were grown for 10 weeks in solutions maintained between 7.3 and 7.5 pH. The seedlings supplied with the metaphosphate had normal green foliage as compared with marked chlorosis in plants in the nonmetaphosphate group. That apple plants are apparently able to utilize phosphorus in the meta form was shown in a phosphorus content in the stem and leaf tissues equally as high in the metaphosphate- as in the orthophosphate-supplied plants.

**Rome trees respond to tillage in central Jersey, E. G. CHRIST.** (*N. J. State Hort. Soc. News*, 24 (1943), No. 1, pp. 1449, 1457, figs. 2).—The plowing in May 1941 of alternate middles in a sod-bound Rome Beauty apple orchard resulted in vigorous growth and greatly increased production the following year on the sides of the trees adjacent to the plowed strips. Fruit color was not as good on the tilled side of the trees, but the greatly increased production more than offset this handicap.

**Influence of submersion of the roots on transpiration, apparent photosynthesis, and respiration of young apple trees, N. F. CHILDERS and D. G. WHITE.** (Ohio Expt. Sta. and State Univ.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 603-618, figs. 9).—The effects on young Stayman Winesap trees, growing on soil in 5-gal. containers, of submerging the roots in water for different periods were studied with the Heinicke-Hoffman apparatus. Experiments were conducted in the field and in an environment-controlled chamber. Transpiration and apparent photosynthesis were reduced within 2-29 days, usually within 2-7 days, following submergence. In some cases the rates of transpiration and apparent photosynthesis became so small with continued submersion that they could not be measured. Apparent respiration was increased within 2 days after submersion, but when the water was drained the rate of respiration returned to near the pretreatment level. Leaf temperature and stomatal behavior could not be correlated with low leaf activity due to root submergence. Leaves from submerged trees contained less water and less ash per unit of leaf surface than did those from check trees. The development of new roots and the formation of root hairs were inhibited by submergence.

**The influence of some spray materials on the internal structure and chlorophyll content of apple leaves,** W. F. PICKETT and C. J. BIRKELAND. (*Kansas Sta. Tech. Bul.* 53 (1942), pp. 54, figs. 18).—An explanation was sought of the factors involved in the reduction in the rate of photosynthesis as caused by certain spray materials commonly applied to apple leaves. The ratios of internally exposed surface in the palisade mesophyll to the internally exposed surface of the spongy mesophyll in the leaves of greenhouse-grown Jonathan, Wealthy, and York Imperial apple trees were in descending order. The palisade mesophyll and the spongy mesophyll comprised 85 and 15 percent, respectively, of the total internally exposed surface. There was a progressive decrease in the percentage amount of palisade mesophyll from the first to the third layer. In orchard trees, the difference between leaves from unsprayed and sprayed trees of a given variety was approximately the same at midseason as at the end of the season. The average number of upper palisade cells per unit area was greater in York Imperial than in Wealthy leaves and greater in sprayed than in unsprayed leaves. The average diameter of the first layer of palisade cells was reduced by sprays and was greater in field than in greenhouse trees. Spray materials checked cell development with each application consistently throughout the season in both greenhouse- and orchard-grown leaves. The so-called mild sprays had less dwarfing effect on palisade tissue than did the stronger materials. The chlorophyll content of greenhouse-grown York Imperial and Wealthy apple leaves was reduced by spraying but not so in the orchard. Under like conditions, the chlorophyll content was much greater in Wealthy than in York leaves, with Jonathan intermediate.

**Commercial hand pollination methods for apples in the Northwest,** J. C. SNYDER. (*Wash. State Col.*). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 183-186, fig. 1).—The methods employed in collecting and applying pollen for the stimulation of fruit production in unfruitful or partially unfruitful varieties are discussed.

**Development of the storage disorder brown core in McIntosh apples,** W. W. SMITH. (*Univ. N. H.*). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 99-103, fig. 1).—A study of records maintained by a commercial storage firm indicated that brown core is more abundant in some years than others and that apples from certain orchards are more susceptible than from others. Observations on apples from 19 orchards failed to show any apparent correlation with fertilizer treatment, but there was some evidence that immaturity at harvest may have predisposed the apples to the injury. Other studies suggested that in years of little brown core maturity at harvest is a factor, but that in severe seasons it plays an insignificant part. An examination of fruits harvested from the north and south sides of McIntosh trees in a year of severe brown core revealed more brown core in fruits from the north side. Checking brown core development with weather conditions, it was indicated that high moisture and low temperature during the ripening period may be conducive to brown core development in the McIntosh apple.

**A study of internal breakdown of Northern Spy apples in storage,** I. BERNSTEIN and R. E. MARSHALL (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 156-162, figs. 3).—Very large Northern Spy apples did not keep well in storage because of susceptibility to internal break-down. Observations on apples from different cultural plots, including irrigation, indicated that differences in break-down susceptibility are associated primarily with size rather than any cultural treatment. In general, apples having the most red color were most susceptible. No significant difference was noted between apples stored immediately after harvest and those held for 1 week at 60° F. Evidence was obtained that increasing

the carbon dioxide content of the storage atmosphere was helpful in decreasing break-down. Spot harvesting of the apples over 3 in. in diameter some 10 days before regular harvest and their use before the middle of December is suggested. When the entire crop is picked at one time, the larger apples should be graded out for earlier disposal.

**Softening and soluble solids in Bartlett pears as influenced by soil moisture, F. W. ALLEN.** (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 106-112).—Examination of pears from orchards or trees receiving different amounts of water showed that fruit from nonirrigated trees was firmer and higher in soluble solids than that from irrigated trees. Soluble solids and total sugars were higher in the juice of "dry" fruit, but the ratio between the two was similar in dry and "wet" fruit. This was also true in comparing ratios of total sugars with total solids in dried pears. Winter rainfall apparently had little effect, as summer irrigation was necessary to maintain an available supply of soil moisture throughout the growing season.

**Sweet cherry rootstocks (Farm and Home Sci. [Utah Sta.], 3 (1942), No. 4, p. 8).**—Sweet cherry trees on mahaleb roots were found superior to those on mazzard or Stockton Morello. The mahaleb-rooted trees were more resistant to wind damage, excessive heat and drought, and to severe winter temperatures.

**The effect of pruning upon the root distribution of peach trees, E. F. SAVAGE and F. F. COWART.** (Ga. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 67-70).—Records on two groups of Mikado peach trees growing in Cecil sandy clay loam, one lot receiving the conventional heavy pruning and the other comparatively light pruning, showed marked differences in growth and fruiting in favor of the light pruning. Lightly pruned 4-yr. trees were even larger than 5-year-old heavily pruned trees. There was no evidence that the degree of pruning had any effect on the nature of the root system except on total growth. Over 90 percent of the total tree roots and about 75 percent of roots less than 2 mm. in diameter were located within 18 in. of the soil surface.

**Vegetative responses of the Elberta peach on Lovell and Shalil rootstocks to high chloride and sulfate solutions, H. E. HAYWARD and E. M. LONG, (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 149-155, fig. 1).—In the case of Elberta peaches on Lovell and Shalil roots grown in sand under differential salt treatments, total concentration of salt was found to be a major factor in the resultant growth depression. There was also evidence that certain specific ionic effects must be considered, e. g., a high concentration of the chloride ion caused certain marked leaf symptoms that did not occur with high sulfate concentration. The chloride ion was more toxic than the sulfate ion at isomotic concentrations. At the control and low-chloride levels trees on Shalil rootstock grew better than those on Lovell when compared with respect to secondary thickening, linear growth, weight, and volume. No significant differences between the two stocks were evident under the sulfate treatments.

**Some results of acidity and catechol tannin studies of peach fruits, M. A. BLAKE and O. W. DAVIDSON.** (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 201-204).—Information is presented on the relative acidity and tannin content of a considerable number of peach varieties. In the very acid group were Duke of York, Fair Beauty, Fertile Hale, J. H. Hale, Mamie Ross, and Greensboro, and in the low acid group Chairs Choice, Mayflower, Goldeneast, Vedette, Admirable Jaune, and Eclipse. In the very high tannin group were Illinois, Mitchelson, General Lee, Golden Giant Cling, and Chinese Blood. Fruits high in both acidity and tannin were especially unpalatable. The crossing of two varieties with very acid fruits resulted in seedlings a high proportion of which bore acid peaches. The crossing of two varieties low in

tannin resulted in a progeny a considerable proportion of which was low in tannin, and reciprocally the crossing of two high tannin peaches yielded a large proportion of high tannin seedlings.

**Additional studies of the acidity and tannin content of mature peach fruits.** M. A. BLAKE. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 153-156).—A continuation of the above study gave further evidence that peach varieties differ markedly in acidity and in catechol tannin content. Although the 1940 and 1941 seasons varied greatly in climatic conditions, such as light, temperature, and moisture, certain varieties developed about the same acidity each year. It was noted that trees which for some reason became exceptionally high in carbohydrates tend to develop fruit exceptionally high in tannin for the variety. However, where such variations in growth status were carefully avoided, it was observed that fruits of certain varieties fluctuate rather widely in tannin from season to season while others are relatively uniform.

**Tennessee Beauty strawberry.** L. A. FISTER and B. D. DRAIN (*Tennessee Sta. Cir.* 81 (1942), pp. [4], figs. 2).—This new variety, obtained from a cross of Missionary × Premier, is described as to plant and fruit characters and uses.

**Pollen-containing sprays for the cross-pollination of Ohanez grapes.** T. C. DUNNE (*Jour. Dept. Agr. West. Austral.*, 2. ser., 19 (1942), No. 3, pp. 210-213).—Pollination of the Ohanez grape was successfully accomplished by spraying the flowers with a water suspension of pollen of a compatible variety. Spraying not only required less labor than hand pollination but was also more economical of pollen. Thorough wetting of the flower clusters was better than a mist application. A measure of control of the degree of fruit setting should be possible by adjusting the concentration of pollen in the water.

**Preliminary studies on modified air storage of the Fuerte avocado fruit.** J. B. BIALE. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 113-118, figs. 4).—Observations on Fuerte avocados stored for different periods in modified atmospheres, one consisting of 10 percent oxygen, 10 percent carbon dioxide, and 80 percent nitrogen, and the other with about one-third to one-half as much oxygen and carbon dioxide, indicated that both modified atmospheres favored the keeping of the avocado. The rate of carbon dioxide evolution was lower in the controlled atmospheres than in air, and apparently no climacteric rise in respiration occurred. Even the second set of conditions gave good results with respect to fruit softening, and the fresh appearance of the skin was maintained better than in air.

**Seed production and seedling yields of some citrus varieties of possible value for rootstock purposes.** E. MORTENSEN and C. R. RIECKER. (Tex. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 145-148).—Evidence is placed on the importance of stock varieties which produce abundant seed capable of developing into rapid-growing, vigorous seedlings. Records taken on seed production of a number of citrus stocks showed the trifoliolate orange to lead, with an average of 45.9 seeds per fruit over a 3-yr. period. When seeds were sown, the citrange group made the best growth during the summer. The Carrizo citrange, trifoliolata, and sour orange rated highest in yield of usable stocks for budding. The Carrizo citrange is considered a promising rootstock for southern Texas.

**Physiological studies of yield, quality, and maturity of Marsh grapefruit in Arizona.** W. E. MARTIN (*Arizona Sta. Tech. Bul.* 57 (1942), pp. [2]+48, figs. 8).—Under Arizona environments citrus fruits often develop a relatively thick rind and coarse external appearance which lowers their market value. The most satisfactory and uniform production over a period of 4 yr. was ob-

tained by winter nitrogen treatments designed to bring about a relatively high nitrogen content in the tree at bloom. Treatments which maintained a high nitrogen content in the summer months following winter starvation resulted in somewhat irregular production tending toward alternate bearing. The use of nonleguminous cover crops, such as Sudan grass, in the spring and summer along with the elimination of nitrogen applications during the same period brought about a mild nitrogen starvation of the tree leading to a higher proportion of fruits of better commercial grades. Fruit from trees of low nitrogen content in autumn developed yellow color much earlier and the juice was sweeter. The size of crop and the age of tree were also factors affecting quality. Treatments restricting irrigation water tended to reduce quality. The winter nitrogen application appeared to have very little effect on quality of the fruit remaining on the tree over winter. If the fruit was of superior quality in autumn, it was usually relatively good in the spring.

**Adjustment of yields in an experiment with orange trees, E. R. PARKER.** (Calif. Citrus Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 23-33).—An analysis of data recorded in a fertilizer experiment with Washington Navel oranges, with a background of prior yields obtained during a 6-yr. uniformity test, indicated that the use of covariance on the yields of the uniformity trial resulted in a reduction in the experimental error. The reduction caused by such an adjustment was greater than that resulting from an elimination, by analysis of variance, of the effects of "yield groups" based on the same prior yields. The author concludes that rather permanent variations which are correlated with the yields during the uniformity trial, and also variations of a more temporary nature which affect areas of the orchard and are reflected by yields of check plats, are responsible for an important part of the variability in the experimental yields. In this experiment, the interpretation of yield effects as influenced by fertilizer treatments, by means of covariance, could be most accurately made by using the concurrent yields of the check plats and the yields of the final uniformity-trial year as independent variables.

**Extending guava production in California, H. J. WEBBER.** (Calif. Citrus Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 228-233).—Information is presented on the climatic and soil requirements of the guava, acreage available for its growth, varieties, vitamin content of fresh and dried fruits, and on commercial preparations.

**The relationship between chlorosis of macadamia seedlings and certain chemical constituents of macadamia seeds, P. GUEST.** (Hawaii Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 61-64).—Observations on 22 lots of seedlings, each from seed of a single-bearing tree and all grown in washed coral sand, showed marked variation in the development of chlorosis. When the chlorotic condition was compared with the amounts of iron and manganese in the kernels, it was found that seeds with a relatively small amount of iron developed into seedlings with the more pronounced chlorosis. Much the same indication was seen for manganese, but when the data were subjected to analysis only iron was associated significantly with the expression of chlorosis.

**Additional studies on delayed foliation of pecan trees, C. W. VAN HORN.** (U. S. D. A. and Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 65-66).—In this second paper (*E. S. R.*, 87, p. 675), DNO spray applied in the dormant season to Burkett pecan trees growing near Yuma, Ariz., is shown to have increased yields significantly over nonsprayed controls. The spray advanced slightly the time of bud break in the Halbert variety, but had no effect on subsequent yields. The two varieties differed apparently in their chilling requirements for breaking dormancy.

**A method of evaluating the nuts of black walnut varieties**, L. V. KLINE (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 136-144, fig. 1).—A new method of judging the nuts of black walnut varieties, based on their income-producing potentialities, is proposed. Since nut development in a given tree varies from year to year, there is a need for conducting tests over a number of years. If the nuts are reasonably well cured, there appears to be no need for moisture determinations except in the case of detailed evaluations of more promising varieties, and here the moisture data should be adjusted to a common base moisture content. The author suggests that 25 nuts, taken at random from a representative lot, constitute an adequate sample except where very precise comparisons are required.

**The influence of delayed hulling on the color and quality of eastern black walnut kernels**, S. B. CHASE (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 131-135, figs. 2).—Both color and flavor of kernels were affected adversely by a delay in hulling, and within certain limits the changes in color and flavor were related directly to the length of time the nuts remained unhulled after maturity. Under the conditions employed it was possible to obtain light-colored, mild-flavored kernels by hulling within 7 days following harvest.

**The production of guayule rubber under irrigation**, G. E. P. SMITH. (Univ. Ariz.). (*Agr. Engin.*, 23 (1942), No. 10, pp. 312, 324, figs. 2).—The author outlines the history of the development of guayule rubber production from the inception of the cultivation of the shrub in 1911 to the present Government-directed projects. Failure of the production of guayule rubber is shown to have been solely the result of a very sharp drop in the price of Sumatra and Ceylon rubber when the first guayule plantings were in their third year.

**Suggestions for the beginner with lilies**, G. L. STATE (*Amer. Lily Yearbook*, 1942, pp. 70-79, figs. 7).—Information is presented on the importance of using disease-free stocks, varieties adapted to the beginner, time of planting, fertility requirements, etc.

**Influence of bulb treatments on growth and flowering of the Easter lily**, R. NELSON (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 105-120, figs. 6).—Mercury compounds, including organic and inorganic and soluble and of low solubility, proved toxic at all concentrations used. Red copper oxide, potassium permanganate, and chloride of lime either caused injury to the bulbs or dwarfed the plants and retarded flowering. Formaldehyde dust mixed with potting soil did not give beneficial results comparable with soaking bulbs for 30 min. in a 1:120 or 1:240 solution of formaldehyde. Formaldehyde solutions were slightly, or not at all, toxic, and sometimes stimulated earlier flowering. Dipping bulbs for 1 min. in a suspension of 1 lb. of wettable sulfur in 1 gal. of water stimulated earlier rooting, advanced germination, and resulted in more vigorous and earlier flowering plants. This treatment of bulbs set outdoors in November increased earliness of spring growth, controlled root rot, and hastened flowering.

**Growth-stimulating substances prevent shoot development on roses in storage**, P. C. MARTH. (U. S. D. A.). (*Amer. Nurseryman*, 76 (1942), No. 11, pp. 7-10, figs. 3).—Several materials when applied to dormant rose bushes in proper amounts and under proper conditions prevented shoot development while the plants were in common storage. Two methods of application were found effective, namely, the use of sprays containing the growth substance in dilute wax emulsion and vaporized chemicals placed in a tight container with the plants. Treated plants when moved to the field became established more quickly, largely because of a much more rapid root formation. Flowering was much better in the treated plants.

## FORESTRY

**American silvics and silviculture**, E. G. CHEYNEY (*Minneapolis: Univ. Minn. Press*, [1942], pp. X+472, figs. 38).—This book was prepared by a member of the staff of the Minnesota Experiment Station.

**Farm forestry in the Lake States: An economic problem**, R. ZON and W. A. DUERR. (Coop. Univ. Minn.). (*U. S. Dept. Agr. Cir. 661* (1942), pp. 34, figs. 2).—Farm woodlands in the Lake States cover some 15 million acres or 29 percent of the entire forest land area. The farm woods fall into three broad belts—the western prairie, the southern woodland, and the northern forest. In the western prairie, woods are mostly in the form of sparse natural stands along streams and planted shelterbelts. In the southern area, the farm woods are woodlands in the true sense but are usually extensively grazed. In the north, woods occupy 43 percent of the average farm area and bring in 12 percent of the farm returns. Farm woods contribute more than one-half of all the timber cut annually in the Lake States. The value of the timber cut on farms amounts to \$44,000,000 per year and returns an average of \$2.92 per acre of woodland. It is estimated that with good management farm woodlands are capable of yielding annual returns of \$5 or more per acre.

[**Forestry studies by the Pennsylvania Station**] (*Pennsylvania Sta. Bul. 429* (1942), pp. 12–13, fig. 1).—Included are reports on a saw timber survey in Clearfield County, by D. D. Stevenson and P. I. Wrigley, and on a study of the effect of the location and character of sugar maple trees on the sugar content of the sap, by Stevenson, W. E. White, and H. Triebold.

**Possibility of simple biochemical tests for differentiation between species of genus Pinus**, N. T. MIROV. (U. S. D. A. coop. Univ. Calif.). (*Jour. Forestry*, 40 (1942), No. 12, pp. 953–954).—The identification of ponderosa pine and Jeffrey pine by means of simple colorimetric tests of their pitch is discussed, with comments as to the desirability of applying similar tests to other conifer species.

**The establishment of a white birch community on cutover pulpwood land in northwestern Maine**, H. J. OOSTING and J. F. REED (*Bul. Torrey Bot. Club*, 69 (1942), No. 9, pp. 647–660, figs. 2).—Studies in Oxford County, Maine, showed that during a 10-yr. period, following the complete removal of a mixed spruce-hardwood forest, a mixed stand dominated by white birch and including the typical species characteristic of the mixed spruce-hardwood forest of the Northeast had become established. White birch, pin cherry, yellow birch, and a limited amount of aspen together appeared to be most important in establishing the first canopy on certain clear-cut sites. Abundant balsam fir, red spruce, and white birch constituted the second layer of the young 10-year-old stands. Observations on a 54- to 60-year-old stand indicated that where white birch gains the ascendancy directly after cutting, it may constitute the important dominant for at least from 54 to 60 yr. After the removal of the mature white birch, this species is not found again until future treatments cause large openings in the forest in which are created a favorable environment for birch. Following the cutting of birch, there develops a typical mixed spruce-hardwood stand, with red spruce, red and sugar maples, and yellow birch as the major components.

**Components of spruce and fir volume as influenced by cutting**, A. B. RECKNAGEL and G. W. ABEL. (Cornell Univ.). (*Jour. Forestry*, 40 (1942), No. 12, p. 962).—A timber cruise in 1941 of northern New Hampshire forest stands, part of which was cut in 1890–92 and part in 1917–20, showed that the relative amount of balsam fir in the stands had increased as a result of the cuttings and

that the original volume had not yet been restored, even on the area cut 50 yr. before. On both of the cut-over areas, however, the stands were young and thrifty, whereas on nearly uncut areas the stand was stagnating.

**Vital statistics for some Douglas-fir plantations, T. T. MUNGER.** (U. S. D. A.). (*Jour. Forestry*, 41 (1943), No. 1, pp. 53-56).—Repeated observations on 12 plantations of Douglas fir established in 1915 and 1916 showed that, despite satisfactory initial survival on 10 of the 12 areas, losses continued and were still occurring. Some of the visible causes of death were drought, freezing, heat, snow injury, brush competition, and rodents and larger animals. Three of the better areas had losses of over 30 percent of their stands by 1941.

**Fire as an ecological and silvicultural factor in the ponderosa-pine region of the Pacific slope, H. WEAVER** (*Jour. Forestry*, 41 (1943), No. 1, pp. 7-14, figs. 4).—The advisability of complete prevention of forest fires in the ponderosa pine region of the Pacific slope is questioned because large areas are growing up to dense stands of white fir, Douglas fir, and incense cedar which prevent the less-tolerant ponderosa pine seedlings from becoming established. It is suggested that the dense stagnating stands of reproduction have aggravated the losses by western pine beetles as a result of competition with the larger trees for the limited soil moisture. When fires do occur, they are exceedingly destructive and tend to convert extensive areas into brush fields.

**Effect of cutting mature lodgepole-pine stands on rainfall interception, C. H. NIEDERHOF and H. G. WILM.** (U. S. D. A.). (*Jour. Forestry*, 41 (1943), No. 1, pp. 57-61, figs. 2).—A study, made in the summer of 1941 in north-central Colorado in a lodgepole pine type at an average elevation of 9,300 ft. and where summer rainfall occurs principally as small showers, showed that the amount of rainfall reaching the soil is materially influenced by cutting practices. On the commercially clear-cut plots 90.5 percent of the moisture reached the soil as compared with 68.3 percent on the virgin uncut plots. A chart and a formula are presented from which rainfall may be estimated for any given cutting treatment in storms of various intensities.

**Drainage of forested swamps, R. B. LeBARRON and J. R. NEETZEL.** (U. S. D. A. coop. Univ. Minn.). (*Ecology*, 23 (1942), No. 4, pp. 457-465, figs. 3).—Following the drainage of a swamp near Dukes, Mich., by the construction of two parallel ditches about 300 ft. apart, arborvitae trees located between the ditches accelerated their growth from two to four times. The vegetation following clear-cutting and draining was dominated by red maple and alder, an ecologically more advanced stage of succession than coniferous bog but of lower commercial value. If commercial species are expected, they must be present before the drainage is undertaken.

**Effect of annual spring fires on stump taper of loblolly pine, H. H. CHAPMAN** (*Jour. Forestry*, 40 (1942), No. 12, pp. 962-963).—Observations on a small area at Urania, La., which had been burned over several times to serve as a firebreak showed the loblolly pines in the burned area to have developed buttressed trunks, apparently as a protective reaction against recurring fires. The excess was confined to the portion of the trunk within 1 ft. of the soil.

**Origin and development of oak stump sprouts as affecting their likelihood to decay, E. R. ROTH and G. H. HEPTING.** (U. S. D. A.). (*Jour. Forestry*, 41 (1943), No. 1, pp. 27-36, figs. 2).—Studies in the George Washington National Forest, Va., showed that species of oak vary as to the age and size when sprouting capacity declines and also in the height growth of sprouts. Sprouts arising lowest on the parent stump were less likely to develop butt rot from the old stump. The tendency for sprouts higher up on the stump to become dominant argues for their early elimination and the encouragement of sprouts of lower

origin. The most effective improvement measures are those undertaken when the stand is less than 20 yr. of age, preferably in the 8- to 15-yr. stage.

## DISEASES OF PLANTS

**The Plant Disease Reporter, [December 1 and 15, 1942]** (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 26 (1942), Nos. 22, pp. 469-485; 23, pp. 487-512, figs. 4).—In addition to the host-parasite check list revision, by F. Weiss (No. 22, *Vaccinium*, and 23, *Viburnum* to *Vitis*, the following are included:

No. 22.—Spread of the common tobacco-mosaic virus in tomato fields by means of vine lifters, by M. B. Linn and H. W. Anderson; early appearance of late blight of potato in Oregon in 1942, by C. E. Owens; diseases of soybeans and peanuts in Mississippi, by J. A. Pinckard; cotton boll rots and the fungi associated with them in Oklahoma in 1942, by W. W. Ray; the rate of application of Ceresan to cottonseed, by W. W. Ray; preliminary evidence suggests guayule may be resistant to the root knot nematode, by W. G. Hoyman; tobacco diseases in Maryland in 1942, by E. A. Walker; and small grain diseases in Virginia, 1942, by S. B. Fenne.

No. 23.—*Phytophthora infestans* was destructive on tomatoes in New York State during 1942, by G. L. McNew; 1942 vegetable diseases in New Jersey as affected by the weather, by C. M. Haenseler; *Helminthosporium turcicum* leaf blight of corn in West Virginia, by E. J. Wellhansen; control of dollar spot in Minnesota, by I. W. Tervet; grass diseases in Wisconsin in 1942, by J. L. Allison and D. W. Chamberlain; red clover diseases in Wisconsin in 1940-41-42, by J. L. Allison; peanut diseases in certain south Texas counties in 1942, by G. KenKnight; and brief notes on *Verticillium* wilt of cotton in Oklahoma, *Phytophthora infestans* on the weed *Solanum sarachoides*, and *Septoria* leaf spot on celtuce in Illinois.

**Abstracts of papers accepted for presentation at the thirty-fourth annual meeting of the [American Phytopathological] Society, New York, N. Y., December 28 to 31, 1942** (*Phytopathology*, 33 (1943), No. 1, pp. 1-20).—Abstracts of 87 papers relating to plant diseases and/or their control.

[Plant disease studies by the Bureau of Plant Industry] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt. 1942*, pp. 13-14, 18-19, 25, 26-27).—Included are statistics on fungi identified for plant disease fighters; and brief reports on defense housing, aircraft, and boat decay; resistant strains for controlling forest-tree diseases; a cotton disease survey; immunity of *Crotalaria spectabilis* to root knot; curly top virus studies; urea as a soil disinfectant; a new fungicide for tobacco blue mold; and increases in *Fusarium* wilt and root knot on tobacco following sweetpotato as compared to healthier tobacco following peanuts.

[Phytopathological work by the Georgia Station]. (Partly coop. U. S. D. A., Ga. Coastal Plain Expt. Sta., et al.). (*Georgia Sta. Rpt. 1942*, pp. 68-69, 70-73, 75).—Brief progress reports are given on diseases of muscadine grapes, fungicidal dusts for peanut leaf spots, peanut seed treatment, the major diseases of snap beans and breeding for resistance to them, and diseases of Austrian Winter field peas, vetches, lupines, lespedezas, and cowpeas.

[Progress reports on plant disease studies by the Kansas Station]. (Partly coop. U. S. D. A.). (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 49-52).—Included are studies of diseases of cereals, forage crops, fruits, and vegetables; combined resistance of winter wheat to leaf and stem rust races; and breeding for disease resistance in wheat, oats, and sorghum.

[Studies of plant diseases by the Montana Station], H. E. MORRIS (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 19-24).—Progress is briefly reported for studies of

wheat bunt and control methods (including resistant varieties), seed treatment for oat smuts, mosaic control in Great Northern beans, and diseases of sugar beets (seedling diseases or "black rot," and phosphate and nitrogen deficiencies) and their control.

[Progress in phytopathological studies by the Oregon Station]. (Partly coop. U. S. D. A.). (*Oregon Sta. Bul.* 401 (1941), pp. 38-39, 39-40, 41-42, 48, 58-59, 63, 68, figs. 2).—Brief reports are included on virus stoney pit disease of pear, viruslike leaf mottling and chlorosis of orchard trees, physiological (?) bud blight of cherry, control of leaf spot and brown rot of cherry, and control of pear scab and storage rot; crinkle, red stele, and stunt (new virus disease) of strawberry, crown degeneration of Cuthbert raspberry, stamen blight of blackberry, and dwarf disease of loganberry; cereal smuts; potato nematode, scab, and virus problems; tomato tip blight and curly top resistance in vegetable crops; and diseases of ornamental nursery stock and of bulbs and ornamental plants.

[Plant disease research in Pennsylvania] (*Pennsylvania Sta. Bul.* 429 (1942), pp. 11, 25).—Tests by H. W. Thurston indicated the possible value of substitute copper sprays for bordeaux against blight and by C. C. Wernham the control of hot weather grass disease with Spergon.

A simple technique for isolating spores of various fungi from exposed slides in aerobiological work, W. J. MARTIN. (Minn. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 75-76).—The technic described involves use of the low power of the microscope for marking the location of a spore or group of spores on an exposed slide with a crow-quill pen and India ink. The slide is then inverted over a Van Tieghem cell and single spores are isolated with a glass needle and micromanipulator, and placed on sterile agar drops. By this method spores of the following fungi which are not morphologically distinctive enough for identification, were isolated and identified: *Penicillium*, *Aspergillus*, *Trichoderma*, *Cephalosporium*, *Fusarium*, *Cladosporium*, *Rhizopus*, and *Pleospora*.

An analysis of factors causing variation in spore germination tests of fungicides.—IV, Time and temperature, R. H. WELLMAN and S. E. A. McCALLAN (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 6, pp. 431-449, figs. 5).—Continuing the series (E. S. R., 86, p. 340), in determining the effect of time in the spore germination methods of fungicidal assay, toxicity curves were established for  $\text{CuSO}_4$ ,  $\text{ZnCl}_2$ , "Standard Laboratory Bordeaux," red cuprous oxide, and two synthetic organic chemicals on four fungus species after various periods of elapsed time and under different temperatures. A linear relation between reciprocal of elapsed time and germination expressed in probits was shown for *Sclerotinia fructicola*, *Glomerella cingulata*, *Alternaria solani*, and *Macrosporium sarcinacforme* spores germinating in water at 10°, 15°, 21°, 27°, and 35° C. Temperature markedly affected the spore germination rate in these fungi in water, but all attained 98 percent or above by 50 hr. at all temperatures, except the first two at 35° where it was about 90 percent. Optima for each fungus are given. No significant difference in precision could be shown between counts made at 6, 12, 24, 48, or 96 hr. A linear relation between reciprocal of elapsed time and germination expressed in probits occurred when spores were germinated in a given concentration of a chemical, provided it permitted germination. The action of elapsed time in fungistatic tests is the reverse of the usual action of time in toxicity tests at a given concentration, and in such tests inhibition of germination becomes less as time passes since the spores continue to germinate and thus give indication of viability. A linear relation is also shown for LD50 values when the logarithm of concentration is plotted against recip-

rocal of elapsed time. This curve is important in assaying a fungistatic agent, since compounds are rated differently at various times on the same fungus and fungi may differ in relative susceptibility to a compound with time elapsed before counting. Slopes of dosage-response curves did not differ significantly for the various times of counting, provided appropriate correction was made for control germination.

Determining temperature effects other than optimum on fungistatic action involves a system where two toxicants, i. e., chemical and temperature, act simultaneously. Interpretation is simplified if the variable time is held constant by determining LD values after 20 hr. or more of elapsed time, when the chemical has approached equilibrium with respect to time. No significant LD50 differences could be demonstrated at 15°, 21°, or 27°, but there was a temperature effect at 10° and 35°. Compounds were not rated in the same order at 10° and 35°, but in general it took less chemical to attain LD50 at these extremes. It took proportionately more chemical to give LD50 on *A. solani* at the higher temperatures and on *S. fructicola* at the lower. In germination tests where 20 hr. or more elapsed before counting, temperature need be controlled only within about 5° above or below the germination optimum. In a general way, time of counting and extreme temperatures are believed as important sources of variation in fungistatic tests as is the difference in fungus susceptibility.

**Revisionary studies in the tropical American rusts of *Panicum*, *Paspalum*, and *Setaria*, G. B. CUMMINS.** (Ind. Expt. Sta.). (*Mycologia*, 34 (1942), No. 6, pp. 669-695, figs. 23).—This paper presents the results of a taxonomic study of 14 species of the Uredinales—*Uromyces* and *Puccinia* (2 new species)—parasitic on these three grass genera. There are 18 references.

**Protoplasmic continuity in the powdery mildew *Erysiphe graminis* DC., II. J. BRODIE** (*Canad. Jour. Res.*, 20 (1942), No. 12, Sect. C, pp. 595-601, figs. 16).—By a technic described, the protoplasm of the mycelium and conidiophores of this barley mildew fungus was found continuous from cell to cell through pores in the septa.

**Physiologic specialization in *Cercospora oryzae*, T. C. RYKER.** (La. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 70-74, fig. 1).—This reports 5 main races of the rice leaf spot fungus which could be further subdivided into 16 subraces. These races were differentiated on size of lesions and length of incubation period on 8 rice varieties. Certain varieties were found resistant to all known races, but Blue Rose, the one most widely planted in Louisiana, proved susceptible to most races known in the State. A selection of this variety is resistant to race 1, which is the most common form there.

**New varieties of spring wheat resistant to stem rust in the Canadian west, and their genetical background, K. W. NEATBY** (*Empire Jour. Expt. Agr.*, 10 (1942), No. 40, pp. 245-252).—The author reviews (21 references) the genetics of resistance in wheat to stem rust, the results of comparative field tests, sources of breeding material, and the distribution of resistant varieties in the Canadian prairie provinces.

**Doenças de mandioca no nordeste [Diseases of cassava in the northeast (Brazil)], J. A. DESLANDES** (*Bol. Min. Agr. [Brazil]*, 30 (1941), No. 2, pp. 23-41, figs. 17).—A brief compendium on the diseases and their control, including those due to bacteria, fungi, viruses, mites, nematodes, and dodder.

**The effect of cotton seed dusting on emergence of seedlings in soil infested with *Rhizoctonia*, W. W. RAY.** (Okla. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 51-55).—In tests involving seed treatment with various fungicidal dusts and planting in soil abundantly infested with *R. solani*, the chemicals regularly giving emergences significantly greater than those of non-

treated controls were New Improved Ceresan (ethyl mercury phosphate), DuBay 1155-HH (ethyl mercury iodide), DuBay 740-A (ethyl mercury borate), DuBay 1228-R (methyl mercury naphthol sulfamide), and Sperguson (tetra-chloro-para-benzoquinone), but the differences in subsequent survival from treated and nontreated seed were not statistically significant. The results thus indicate that seed treatment is not an effective means of controlling post-emergence damping-off of cotton by *Rhizoctonia* when the soil is heavily infested.

**Las enfermedades del algodón en la Republica Argentina** [Cotton diseases of Argentina], M. A. DI FONZO (*Argentina Min. Agr., Junta Nac. Algodón, Bol. Mens. No. 80 (1941), pp. 951-978, figs. 28; also [Pub.] No. 58 (1942), pp. [3]+30, figs. 28*).—This conspectus (illustrated partly in color) includes diseases due to cryptogams and nematodes and abnormal conditions ascribed to meteorological and physiological causes. Control methods discussed include plant and seed treatments and  $H_2SO_4$  delinting of the seed. Instructions for preparing and sending specimens are included.

**Principales enfermedades que se presentan en el cultivo de la papa en Panamá** [Principal potato diseases in Panama], J. I. MARTINEZ MORENO (*Rev. Agr. y Com. [Panama], 1 (1941), No. 1, pp. 47-53, figs. 5*).—A brief conspectus of the diseases and their control, with bibliography.

**Diagnosis of the bacterial ring rot of the potato**, W. H. BURKHOLDER (Cornell Univ.). (*Amer. Potato Jour., 19 (1942), No. 10, pp. 208-212*).—The difficulties in diagnosing *Corynebacterium sepedonicum* (= *Phytophthora sepedonica*) and various published laboratory procedures are reviewed (9 references). It is concluded that if one is familiar with potato diseases in the living plant, ring rot can in most cases be diagnosed by symptoms alone. Where there is some doubt, macroscopical examination under ultraviolet light and microscopical examination for the gram reaction and bacterial morphology should enable a satisfactory conclusion, but any one test alone is insufficient for definite proof.

**Potato virus diseases: Review of literature, 1941**, T. P. DYKSTRA. (U. S. D. A.). (*Amer. Potato Jour., 19 (1942), No. 12, pp. 267-279*).—With 28 references.

**Tuber-line seed plots**, D. FOLSOM. (Maine Expt. Sta.). (*Amer. Potato Jour., 19 (1942), No. 11, pp. 225-229*).—Tuber lines were helpful but insufficient for developing mosaic- and leaf roll-free seed stocks in Maine. When such stocks were planted in seed plots, there was about a 50-50 chance that disease would enter them. Mosaic control was favored by location outside the northeastern part of the State, by earliness, and by larger size and better isolation of seed plots. Leaf roll control was favored by location in the northeastern part of the State, by earliness, and by larger size of seed plots. The effects of these factors were often greater than the effects of tuber-unit planting.

**A strain of the tuber blotch virus causing top necrosis in potato**, P. E. M. CLINCH (*Roy. Dublin Soc., Sci. Proc., n. ser., 22 (1942), No. 46, pp. 435-445, pl. 1*).—A "top necrosis element" was found in certain units of the stock cultures in President potato of interveinal mosaic, previously shown to be a mixture of viruses F (tuber blotch) and X. As the parent plant of the clone and other units arising from it were free from this element, it was assumed to be a contaminant. Removal of X from interveinal mosaic showing top necrosis yielded a supposed complex of the top necrosis element and virus F, referred to as virulent tuber blotch. The last, inoculated into 32 potato varieties gave 18 killed by top necrosis and 14 with a mild reaction identical with that of virus F. The reactions of 8 other solanaceous hosts, as well as the physical properties of virulent tuber blotch virus, proved similar to those of virus F. Evidence is presented that the top necrosis element is not related to potato viruses B, C, or D, which also cause top

necrosis. *Myzus persicae* failed to transmit any virus from this variety infected with virulent tuber blotch alone, but in the presence of A (a condition necessary for transmission of F), virulent tuber blotch, as such, was transmitted in a single case. Potato plants infected with virus F were immune to virulent tuber blotch, and virus G (aucuba mosaic) and virulent tuber blotch were also mutually protective. It is concluded that virulent tuber blotch is a strain of virus F (= *Solanum* virus 8 = *Marmor aucuba*), which arose spontaneously from the latter within the plant tissues. By its recognition the Koch and Johnson "potato streak" virus (E. S. R., 74, p. 502) is identified. Cases of virus strain conversion in the literature are discussed. There are 22 references.

**The identity of the top-necrosis in Up-to-Date potato,** P. E. M. CLINCH (*Roy. Dublin Soc., Sci. Proc., n. ser., 23 (1942), No. 4, pp. 18-34, pl. 1*).—Of 39 potato varieties tested, the majority reacted with top necrosis when grafted with scions from "streak"-carrying Up-to-Date potato. Sap inoculation of streak virus (=virus B = *Solanum* virus 4) from Up-to-Date to healthy potatoes of intolerant varieties resulted in local necrotic lesions rarely becoming systemic. It was easily transmitted to tolerant varieties. Sap inoculation from Up-to-Date to *Datura stramonium*, tobacco, tomato, or *Lamium hybridum* resulted in mild mosaic symptoms characteristic of virus X. All attempts to infect X-immune seedling 41956 with a virus from Up-to-Date or with virus X failed, though the variety was readily infected with potato viruses unrelated to X. When this seedling was inserted as an intermediate scion between Up-to-Date and a susceptible basal stock, the virus content of Up-to-Date passed unchanged into the basal stocks. In similar double grafts in which Up-to-Date was replaced by X-infected President as top scion, no resistance was offered by the intermediate 41956 scion to downward passage of X, though the latter scion failed to become infected with X or any virus from Up-to-Date. Removal of X from Up-to-Date sap resulted in a simultaneous removal of the virus responsible for streak. The physical properties of the Up-to-Date streak virus proved similar to those recorded for X-type viruses. The streak virus could not be introduced by sap inoculation to potato or *Datura* already infected with virus X, but the immunity of X-infected plants to the streak virus or to other strains of X did not hold if the second virus was introduced by graft. After inoculation with streak sap from Up-to-Date, healthy potatoes of intolerant varieties occasionally developed systemic infection with a nonnecrotic X virus, whereas similar plants inoculated with a mixture of streak and X-infected saps all developed systemic X infection. It is concluded that the streak virus in Up-to-Date potato is a strain of virus X differing from typical X only in its effects on certain potato varieties. Pertinent related data are discussed. There are 26 references.

**"Stem end browning" and "net necrosis" in potatoes,** H. T. Gussow (*Amer. Potato Jour., 19 (1942), No. 12, pp. 280-282*).—A brief discussion of the significance of these two disease entities, followed by the advice that until the causes are definitely ascertained the safe procedure is to plant no seed potatoes showing the slightest evidence of either.

**The production of virus-free potatoes in the south-west of England,** J. CALDWELL (*Ann. Appl. Biol., 29 (1942), No. 3, pp. 265-267*).—Preliminary surveys followed by field trials in certain isolated districts led to the conclusion that large quantities of seed potatoes could readily be produced in three main areas and probably in many more, and in many cases under conditions least suited to other forms of agricultural activity.

**The severity of potato scab in relation to the use of neutralized and one-third neutralized fertilizers,** H. T. COOK and G. V. C. HOUGHLAND. (Va.

Truck Expt. Sta. and U. S. D. A.). (*Amer. Potato Jour.*, 19 (1942), No. 10, pp. 201-208, fig. 1).—The evidence presented is believed to show that the neutralized and one-third neutralized fertilizers used continuously for 7 yr. ultimately affected the occurrence and amount of potato scab principally through their effects on the degree of acidity of the soil.

**The amount of boron absorbed by soybean plants and its effect on their growth**, W. S. HODGKISS, R. H. HAGEMAN, and J. S. MCHARGUE. (Ky. Expt. Sta.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 652-660, fig. 1).—Short-term growth studies on soybeans indicated that a 20-day growth period with 12-day treatment suffices for demonstrating boron toxicity both by growth relationships and by foliar symptoms. Toxicity as shown by foliar symptoms corresponded to the presence of 200 p. p. m. or more of B in the moisture-free material. Duplication of growth maxima in four plant series in sand and sand-soil mixtures and treatment with varying amounts of B appeared to furnish conclusive proof that such maxima occur at 0.4 and 0.8 p. p. m. added B at this stage of soybean growth. Preliminary field tests indicated a growth change corresponding in effect to that in the greenhouse work. The B concentration of field-grown soybeans at midseason showed little difference among treatments, but at earlier and later growth stages the concentration had increased with treatment. This procedure offers a method for testing small amounts of soil for B toxicity in a relatively short time.

**The iron-manganese relation in plant metabolism**, I. I. SOMERS and J. W. SHIVE. (N. J. Expt. Stas.). (*Plant Physiol.*, 17 (1942), No. 4, pp. 582-602, figs. 6).—In tests with soybean in solution culture at 3 Fe levels at each of which the Mn concentrations were varied through a relatively wide range, pathological symptoms produced by excess Fe were identical with those in Mn deficiency, and vice versa. The Fe:Mn ratios in the nutrient corresponding to good growth and normal development fluctuated within a narrow range around 2.0, regardless of the total concentrations of these elements within the limits used. The Fe:Mn ratio values above this effective range invariably produced a specific type of chlorosis resulting from excess Fe or deficient Mn, or both; ratios below this, a specific chlorosis of a different type resulting from excess Mn or deficient Fe, or both. Ratios of soluble Fe to soluble Mn within the tissues associated with good growth and development covered the same range of values as those in the external medium, though the range of effective values might be somewhat wider in plant tissues than in the substrate. Variation in the ratios of the soluble fractions either above or below this effective range resulted in specific pathological symptoms. High concentrations of soluble Mn in the tissues were invariably associated with low concentrations of soluble Fe, and vice versa. This suggests the oxidation of ferrous to ferric ions by active Mn, resulting in the inactivation and precipitation of Fe in the form of ferric organic complexes. In their metabolic functions, Fe and Mn are definitely interrelated, the biological effectiveness of the one being determined by the proportionate presence of the other. There are 20 references.

**Resistance of tobacco to bacterial wilt (*Bacterium solanacearum*)**, E. E. CAYTON and T. E. SMITH. (U. S. D. A., N. C. Expt. Sta., et al.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 12, pp. 547-554, figs. 3).—Search for resistance to *Phytophthora* was begun in 1934. None of the wild *Nicotiana* species tested showed resistance, but of 1,034 collections of *N. tabacum* (chiefly from Mexico and Central and South America) a very few were resistant. By crossing two moderately resistant strains, T. I. 79A and Turkish Xanthi, a highly resistant genotype (79-X) was developed, though it is a very poor type of tobacco. A highly wilt-resistant collection of good type (T. I. 448A) was obtained from Colombia, this strain over a 3-yr. period always showing less than 10 percent mortality,

even though disease conditions were so severe that susceptible tobacco was completely destroyed. It was also highly resistant to common tobacco mosaic.

**Viscosimetric studies on the tobacco mosaic virus protein, II, V. L. FRAMPTON.** (Cornell Univ.). (*Arch. Biochem.*, 1 (1942), No. 1, pp. 83-92, figs. 4).—Following the demonstration of anomalies in the viscosity of this virus nucleoprotein (E. S. R., 81, p. 662), this study shows that the degree of anomaly is greatly increased in presence of dilute KCl, the flow of the virus nucleoprotein sol through a capillary tube is discontinuous, and the degree of thixotropy rises with decreasing pH. There are 26 references.

**Effect of water extraction from leaves of tobacco on acyl derivatives of the protein of tobacco mosaic virus, P. AGATOV** (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 33 (1941), No. 2, pp. 170-171).—Since the acyl derivative of this virus protein was not found of usual occurrence in the plant, it is believed that the enzyme system of the plant is unfitted to break up so stable a compound easily and quickly. Hence an acylated molecule of the virus protein appears capable of forming the virulent substance without preliminary hydrolysis of the acyl groups.

**Effect of cyanide on synthesis of ring-spot and mosaic viruses in tobacco, M. W. WOODS.** (Md. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 77-80, fig. 1).—The influence of 0.00015 to 0.0003 M KCN on synthesis of virus proteins of ring spot (*Annulus tabaci*) and two strains of tobacco mosaic (*Marmor tabaci*) was determined by a detached leaf technic. It was possible to follow simultaneously the development of two viruses in sectors of a single leaf under four different experimental conditions. At the concentrations used, KCN inhibited part of the  $O_2$  respiration in the susceptible cell and the synthesis of all three viruses. The effect was also reversible. When ring spot-inoculated tissues were treated with KCN at night only, the cells became permanently resistant to necrotic action of the virus. An external supply of  $NO_2$  influenced the symptom picture produced by each virus.

**Use sphagnum to control damping-off, P. P. PRONE** (*New Jersey Stas. Nursery Disease Notes*, 15 (1942), No. 5, pp. 17-20).—In view of the need for conserving fungicidal chemicals, attention is called to the value of a layer of shredded sphagnum in seed flats and coldframes as shown by experience of florists and nurserymen and observations by the author.

**Boron for preventing breakdown in beets, A. G. B. BOUQUER.** (Oreg. State Col.). (*Canning Age*, 23 (1942), No. 12, pp. 633-635, fig. 1).—A brief summary of data on this physiological trouble and its control not only in beets but also in carrots, celery, crucifers, and in other vegetables. Lists of sensitive and tolerant crops are included.

**Genes for resistance to powdery mildew in Cucumis melo, T. W. WHITAKER and D. E. PRYOR.** (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 270-272).—Inclusive of new data here presented, the evidence appears to justify carrying forward a number of lines of cantaloup on the ground that a few will contain a full complement of resistant genes, to render advisable the collecting of the fungus *Erysiphe cichoracearum* from a wide range of localities for testing as many biotypes of the pathogen as possible, to demonstrate the importance of maintaining collections of material from areas in which the host species is endemic, and to emphasize the importance of rigorous testing of material in both greenhouse and field. All these steps are especially needed because of the problem of variation in two organisms—the host and the parasite.

**Disease symptoms in lettuce and celtnce, caused by the bean leaf hopper Empoasca solana [solani] Del., J. P. MARTIN and C. E. PEMBERTON** (*Hawaii. Planters' Rev. [Hawaii. Sugar Planters' Sta.]* 46 (1942), No. 3, pp. 111-118,

*figs. 8*).—This disease, described on lettuce and celtnce with the symptoms also recorded on endive, appears to be the first report for the Hawaiian Islands. It is concluded on experimental evidence that the injury results from a toxic secretion by the leafhopper into the leaf during its feeding, the degree of injury varies directly with the insect population, affected plants recover after the insects are removed, and control will be in direct proportion to leafhopper control. The disease is a form of hopperburn.

**Pathogenesis of *Ditylenchus dipsaci* in seedlings of *Allium cepa*, A. G. NEWHALL** (*Phytopathology*, 33 (1943), No. 1, pp. 61–69, *figs. 2*).—Through a study of paraffin sections of onion seedlings up to 12 days old and lifted at 2-day intervals from heavily infested soil, the nematode was found to penetrate the seed soon after germination commenced and to live for a short time in the parenchyma tissues beneath the hilum or in the cotyledon. Penetration of the cotyledon after its protrusion apparently could take place directly through the young epidermis. Once within the sprout longitudinal and radial migration occurred freely through the cortical tissue but was definitely bounded by dermal layers even at early germination stages. No evidence of penetration of the provascular strand was observed. Evidence that this nematode migrates only between the cells by dissolving the middle lamella was meager and unconvincing, but indications of destructive mechanical intracellular penetration of parenchyma tissue were abundant. Further data are presented showing that as seedlings reach the age of 3 weeks they become more resistant to attack in the soil. This may be due to probable increased hardening of the epidermis.

**Etude biologique de *Puccinia allii-phalaridis* Klebahn [Biological study of *P. allii-phalaridis*], E. MAYOR** (*Ber. Schweiz. Bot. Gesell.*, 51 (1941), pp. 313–320).—Includes data on inoculations of this rust into various species of *Allium*.

**Control of tomato diseases** (*Farm and Home Sci.* [Utah Sta.], 3 (1942), No. 4, p. 8).—Hybrids from crossing the wild Peruvian tomato with the Stone and Century varieties were found to have resistance to *Verticillium* wilt. Progress was also made in the breeding of tomatoes (in cooperation with the U. S. Department of Agriculture) for resistance to curly top, but to date the cultural practice of setting tomato plants more closely in the field was the most effective approach to control of this disease. Close planting reduced the amount of disease and increased total yields. Direct seeding in the field and early planting were also beneficial.

**New crystalline forms of tomato bushy stunt virus, S. S. COHEN** (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 104–105, *figs. 2*).—The finding of two more crystalline forms of this virus is believed to emphasize again its relationship to many of the simpler proteins, which are expected to behave according to chemical and physical laws.

**Experimental control of damping-off in tomato seedlings transplanted from sand, including the immediate application of fungicidal drenches, W. S. BEACH and S. Y. CHEN (CHAN)** (*Pennsylvania Sta. Bul.* 434 (1942), pp. 26, *figs. 4*).—No significant evidence was found that lack of balance or omission of certain nutrient elements affects susceptibility of tomato seedlings to damping-off in sand cultures, or that there are differences between properly grown seedlings in sand culture v. steamed soil after transplanting to infested soil. However, overconcentration of nutrient salts resulting in chemical injury increased susceptibility. Washing the sand in hot water is thus essential for each seedling crop to remove excess soluble salts and organic matter as well as to destroy fungi. Reduction of the moisture in seed flats did not appreciably affect resistance if seedlings were transplanted soon after emergence. Extra  $K_2SO_4$  slightly increased resistance but a high moisture level was required to avoid chemical

injury. After transplanting, seedlings were highly susceptible to *Pythium ultimum* for about 3 days and to *Rhizoctonia solani* for a much longer or an indefinite period. Thorough drying of *Pythium*-infested soil largely prevented damping-off of transplanted seedlings, as their highly susceptible period was passed before sufficient mycelial development for attack. Environmental factors favoring prompt renewal of turgor and growth reduced infection. Under conditions of moderate disease, reducing losses by about half proved possible through use of sand or steamed soil as compared with untreated soil, but in averting severe losses, prevention of conditions favoring development of the pathogens in the transplanting soil is far more important than resistance or source of seedlings. In absence of other preventive measures, safe and effective control in transplanted seedlings proved possible through applying comparatively weak drenches of  $\text{CuSO}_4$ , Seme-san, or Spergon to prepared flats of soil just before or after transplanting.

**A septoriose do tomateiro** [Tomato septoriose], J. SOARES BRANDÃO, JR. (*Bol. Min. Agr. [Brasil]*, 30 (1941), No. 11, pp. 19-21).—A note on *Septoria lycopersici* and its control.

**Sulphur and copper sprays in relation to apple-tree growth and yield**, H. W. THURSTON, JR., and H. N. WORTHLEY. (Pa. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 56-60, figs. 2).—When Stayman apple trees were differentially sprayed (1936-41) with standard lime sulfur and lead arsenate v. copper phosphate-lime bentonite and lead arsenate v. unsprayed controls, trunk circumference records indicated a close negative correlation with yields, the loss of crop on unsprayed trees being reflected in increased growth. No cumulative injurious effects from continued use of the sprays were observed.

**Estudio de la naturaleza de las ramas del duraznero (*Prunus persica* Sieb. et Zucc.) y su relación con la gomosis** [Studies of the nature of peach twigs and its relation to gummosis], J. C. BERTELLI (*Rev. Asoc. Ingen. Agrón. [Montevideo]*, 14 (1942), No. 3, pp. 43-89, figs. 8; *Eng. abs.*, p. 87).—Following descriptions of the methods of technique used and the substances of which the normal tissues are composed, the results are presented of studies of peach-twig sections grown in the fall, in the spring and less than a year old, and of those over a year old, and in addition observations of living twigs placed in alkaline or acetic solution. From this work it is concluded that the gummy exudation from peach twigs and branches is due to the degradation of the hemicellulose, hydrocellulose, and pectic substances of the cellular membranes in the bark, pericycle, wood, and pith, as well as of the cell contents of these tissues, together with a hyperplastic process causing formation of gelatinous cells by the cambium.

**Peach wart**, E. C. BLODGETT. (Idaho Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 21-32, figs. 3).—This virus disease of peach, first described by the author in 1939 (*E. S. R.*, 81, p. 655), is now reported only from Idaho, Washington, and Oregon, along with the progress of investigations of the past 5 yr. It is characterized by smooth or rough outgrowths of fruit tissue, and gumming is usually present and often severe. The virus is readily transmitted by budding and persists in the tree. Peach is the only known host. Spontaneous spread, although slow, takes place. The virus has been tentatively named *Galla verrucae*, although little is known of its characteristics. Control is by eradication of diseased trees and use of healthy propagating wood.

**Citrus decline in the Murrumbidgee Irrigation Area: Importance of *Phytophthora* root rot**, L. FRASER (*Agr. Gaz. N. S. Wales*, 53 (1942), No. 9, pp. 415-419, figs. 2).—The progressive decline in the condition of citrus trees in orchards of this New South Wales area during the past 8-10 yr. is shown to be due in part to attacks of the fibrous and even main roots by *P. citrophthora*. The factors which have led to the building up of high concentrations of this fungus

in the soil are discussed, and suggested management methods for control are outlined.

**Cinchona production**, A. G. KEVORKIAN (*Puerto Rico Sta. Rpt. 1941, pp. 9-10*).—A brief note on a virus disease, a fungus-induced stem canker, and two root diseases definitely established as important limiting factors in the development of vigorous trees of *Cinchona* spp.

**A chlorosis and necrosis of tung leaves associated with low potassium content**, M. DROSDOFF and J. H. PAINTER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 45-51, fig. 1).—The effect of mulch in increasing the K content of the leaves and in preventing the development of the interveinal chlorosis is believed to support the hypothesis that the condition here described is the result of K deficiency. There are 16 references.

**"Heterosporium echinulatum" (Berk.) Cke., nuevo parasito del clavel ("Dianthus caryophyllus") en la Republica Argentina**, M. D. CAMPI (*Lilloa*, 8 (1942), No. 1, pp. 269-271, pl. 1, fig. 1).—Recorded for the first time in Argentina, this fungus was troublesome for carnations under glass.

**A leaf-spot of Hibiscus sp. induced by Phytonomonas syringae**, C. O. SMITH. (Calif. Citrus Expt. Sta.). (*Phytopathology*, 33 (1943), No. 1, pp. 82-84, fig. 1).—Water-soaked brownish or blackish spots 1-10 mm. in diameter on the leaves of hibiscus in California were proved due to *P. syringae*. Inoculations through wounds in lemon fruits and in the leaves of hibiscus and lilac gave typical black necrotic lesions, and a culture isolated from black pit of lemon caused lesions in hibiscus typical of the spontaneous disease.

**Erwinia carotovora**, the cause of a soft rot in orchids, *Cattleya* sp., D. P. LAMBER and B. A. FRIEDMAN. (U. S. D. A.). (*Phytopathology*, 33 (1943), No. 1, pp. 80-82, fig. 1).—Spontaneous infection of cattleyas in two New Jersey orchid houses and successful inoculations on excised leaves of *Oncidium*, *Odontoglossum*, *Brassavola*, and *Lockhartia* are reported.

**Ring spot on Saintpaulia**, G. H. POESCH. (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 381-382).—Preliminary trials to determine the cause of the fantastic bright yellow ring patterns developing on leaves of greenhouse grown *S. ionantha* which have been troubling commercial growers appear to indicate a role of overhead irrigation with water considerably cooler than the temperature of the leaves.

**Fusiform rust control in forest-tree nurseries**, B. SLEETH (*Phytopathology*, 33 (1943), No. 1, pp. 33-44, fig. 1).—Effective but not complete nursery control of *Cronartium fusiforme* was obtained by spraying. Of three fungicides used, bordeaux (8-8-100) appeared most effective, Copper Hydro slightly less so, and dry lime-sulfur least effective. Both Santomerse S and an emulsion of raw linseed oil and liquid fish-oil soap gave good results, slightly better than casein, as spreaders. An oak-free zone 1,500 ft. wide failed to show perceptible reduction of rust in slash pine seedlings. Mid-April-sown slash pine showed only three-fifths as many fusiform-rust cankers as that sown a month earlier. Less infection occurred in loblolly than in slash pine sown on the same date and comparably grown, and longleaf pine seedlings proved still more resistant. Neither para- nor ortho-toluenesulfonylamide, applied to the soil surface at about the time of peak sporidial production, gave any reduction in cankered seedlings.

**Distribution patterns in Melampsorella in the national forests and parks of the Western States**, S. M. PANDY (*Mycologia*, 34 (1942), No. 6, pp. 606-627, figs. 3).—Further evidence (E. S. R., 87, p. 530) for the existence of two species of *Melampsorella* was obtained from this study of their distribution on the *Abies* and *Picea* hosts and in some 18 national forests and parks of the United

States (1941), involving 75 collections and over 150 detailed observations. In practically every area one or the other fungus species was dominant even though both hosts were abundant, indicating that the two differ in physiology as well as in morphology. Two distinct distribution patterns were thus obtained. In the Rocky Mountain States where the two hosts are abundant the disease was found more severe than hitherto believed, many trees being partially or completely killed and others dwarfed or stunted. In some Wyoming areas it was of epidemic proportions. Trunk infections were particularly harmful and in young trees soon caused their death. Differences in growth habits inducing compact brooms in *Abies* and irregular diffuse brooms on *Picea* were a constant and fairly reliable character and are believed due to apical dominance, which is present in *Picea* spp. and absent in *Abies* spp.

**Chemotherapy for vascular diseases of trees**, J. G. HORSEFALL and G. A. ZENTMYER. (Conn. [New Haven] Expt. Sta.). (*Natl. Shade Tree Conf. Proc.*, 17 (1941), pp. 7-18).—A general address on the subject, with bibliography and discussion.

**Stand improvement of northern hardwoods in relation to diseases in the Northeast**, W. A. CAMPBELL and P. SPAULDING (*U. S. Dept. Agr., Forest Serv., Allegheny Forest Expt. Sta. Occas. Paper 5* (1942), pp. [2]+25, pls. 9).—Attention is called to certain fungus diseases hampering the production of profitable crops of northern hardwoods (sweet birch, paper birch, yellow birch, red maple, sugar maple, American beech, black ash, American ash, American basswood, black cherry, quaking aspen, and bigtooth aspen) in the northeastern United States, and it is shown how timber stand improvement operations can be directed toward reducing these losses. Detailed discussions concern such matters as estimating disease cull and the average cull to be expected, distribution of cankers and rots by tree age and species, the sprout problem, and the specific diseases and fungi themselves. Brief reference is made to burls and stains.

**Occurrence of *Gonatorrhodiella highlei* in Nova Scotia and New Brunswick**, J. EHRLICH (*Mycologia*, 34 (1942), No. 6, p. 705).—A note on this fungus growing in association with *Nectria coccinea* and the woolly beech scale (*Cryptococcus fagi*) on diseased American beech (*Fagus grandifolia*) in Canada.

**The behavior of *Endothia parasitica* on chestnut trees in California**, M. R. HARRIS (*Calif. Dept. Agr. Bul.*, 31 (1942), No. 3, pp. 99-109, figs. 6).—Chestnut blight, known to have been in California since 1934, has spread from one orchard to two others in the San Joaquin Valley, but the spread has been slow as compared with that in the Eastern States. All infected trees in these orchards were destroyed, and those subsequently developing infection were similarly treated at two annual inspections. Most of the cankers were found at the base of the tree. Earthen dikes to protect against infection by irrigation water were thrown up around the trees in two of the orchards, and the disease has decreased as inspection and eradication have continued. No ascospores have been known to develop in the California area, probably due to the very light summer rainfall. Other environmental factors do not differ greatly from the East. It is believed possible to eliminate the disease by preventing spread through irrigation water or contaminated tools.

**Distribution of *Beauveria bassiana* on elm insects in the United States**, P. V. MOOK and D. O. WOLFENBARGER. (U. S. D. A.). (*Phytopathology*, 33 (1943), No. 1, pp. 76-77).—This adds Pennsylvania and New Hampshire as new locations for *B. bassiana* and gives *Hylurgopinus rufipes*, *Magdalis barbata*, *M. armicollis*, *Saperda tridentata*, and *Tremex columba* as hitherto unreported insect hosts of the fungus from the United States. Of 5,656 insects cultured, *B. bassiana* was isolated from 168.

A disease of the Scots pine (*Pinus sylvestris* L.) caused by the fungus *Diplodia pinea* Kickx associated with the pine spittle-bug (*Aphrophora parallela* Say.).—I, Symptoms and etiology, W. R. HADDOW and F. S. NEWMAN (*Roy. Canad. Inst., Trans.*, 24 (1942), pt. 1, pp. 1-18, pl. 1, fig. 1).—Following a review of the literature (32 references) of *D. pinea*, descriptions are given of the fungus and its natural history, and of the symptoms induced by it in Ontario following infestation of the trees by spittle bugs. The fungus was regularly isolated from spontaneous lesions, injection of spores into terminal shoots caused tip blight, and typical crown blight was induced by application of spores to a branch infested with the insect. Observations on the pine spittle bug and its work are recorded.

Experiments on chemical control of damping-off in *Pinus resinosa* Ait., L. P. V. JOHNSON and G. M. LINTON (*Canad. Jour. Res.*, 20 (1942), No. 12, Sect. C, pp. 559-571).—Of a wide range of chemicals tried, Semesan solutions (1:100 to 1:150) applied to the soil consistently gave the best control in both greenhouse and nursery, and red copper oxide suspensions (1:250 to 1:500) were also effective, particularly in the greenhouse. Both the latter and zinc oxide as dusts for seed treatment gave good control in the greenhouse. Combinations of seed and soil treatments were not more effective in the greenhouse than either used separately, and under certain nursery conditions they were less so. As a group, fungicides generally proved more effective than acidifying agents such as  $H_2SO_4$  or  $Al_2(SO_4)_3$ . The latter appeared to give good control in seasons of normal rainfall, but were more or less ineffective in dry seasons with relatively large amounts of slightly alkaline irrigation water or in wet seasons with excessive percolation. Seedlings from 2-year-old red pine seed of somewhat reduced vitality proved more susceptible than those from 1-year-old seed. White spruce, used in some of the preliminary tests, proved much less susceptible than red pine, though similar in response to the various treatments.

Spread of white-pine blister rust in 1941, L. R. TEHON (*Amer. Nurseryman*, 76 (1942), No. 5, p. 22).

Latest recommendations on control of [Endoconidiophora] canker stain of London plane, P. P. PIRONE (*New Jersey Stas. Nursery Disease Notes*, 15 (1942), No. 6, pp. 21-24).

Susceptibility of wood to decay: Effect of urea and other nitrogen compounds, F. H. KAUFERT and E. A. BEHR. (Univ. Minn.). (*Indus. and Engin. Chem.*, 34 (1942), No. 12, pp. 1510-1515, figs. 2).—The decay rate and susceptibility of southern pine sapwood and Douglas fir, red oak, and cypress heartwoods were not appreciably affected by adding small amounts of urea and ammonium sulfate and phosphate, but higher concentrations of these compounds caused marked reductions in decay. Concentrations approaching those used for chemical seasoning or fireproofing prevented growth of wood-rotting fungi on the test blocks of the woods used. Small concentrations of the organic nitrogen compounds asparagine and peptone increased the decay rate of southern pine sapwood and red oak heartwood, but had little or no effect on that of Douglas fir heartwood, while cypress heartwood showed no signs of decay. These nitrogen compounds thus appear to be more readily utilized by wood-rotting fungi than urea or the ammonia compounds, but the practical significance of the decay increases observed are questioned. Addition of certain soil bacteria to urea-treated wood did not appear to affect its susceptibility to decay by wood-rotting fungi. Heating urea-treated wood to 70°-100° C. for 12-14 hr. caused considerable decomposition and loss of urea, but also appeared to fix some of the urea in the wood so that it was difficult to remove it by leaching. Except for such urea-treated wood, heated as above noted, all the nitrogen compounds were easily leached from wood.

**The calorific value and chemical composition of decayed cordwood, M. T. HILBOEN and F. H. STEINMETZ.** (Univ. Maine). (*Phytopathology*, 33 (1943), No. 1, pp. 45-50).—As causes of decay in red maple, paper birch, and beech, several white-rot but no brown-rot fungi were known to be present. Although determinations per gram had indicated the loss in calorific value to be slower than the loss in wood substance, showing a change in chemical composition during decay, chemical analysis failed to demonstrate a correlation of reduction in calorific value with the amount of any chemical component. In these analyses the white rots exhibited a depletion of both cellulose and lignin proportional to the loss of wood substance, but no correlation between alkali solubility and loss of any other component. In addition, one characteristic of the brown rots was found, viz, a preferential selection of the pentosans in cellulose. After grinding in a hammer mill, particle size resulting from mechanical screening of the reduced sample was found to influence calorific value, very small particles being higher.

### ECONOMIC ZOOLOGY—ENTOMOLOGY

**[Investigations in economic zoology and entomology by the Montana Station]** (*Montana Sta. [Bien.] Rpt. 1941-42*, p. 37).—A progress report (E. S. R., 84, p. 642) by H. B. Mills notes as newly introduced pests the spinose ear tick, screwworm fly, and sweetclover weevil.

**[Investigations in economic zoology and entomology]** (*Pennsylvania Sta. Bul. 429* (1942), pp. 11-12, 13, 19-23, 37, figs. 3).—A progress report (E. S. R., 87, p. 546) noting studies by C. A. Thomas, R. D. Casselberry, L. J. Bennett, H. N. Worthley, H. M. Steiner, D. E. H. Frear, and B. D. Gleissner on wireworm control, browse and acorns as emergency foods of deer, wildlife as a valuable Pennsylvania resource, apple spraying, pistol casebearer control, sprays for plum curculio, spray tests, coal tar products for insecticides, ethylene dichloride unsafe on peach trees, control of grape berry moth, and the use of mixed thiocyanate and pyrethrum dusts for mushroom fly control.

**[Work with fur-bearing animals in Alaska]** (*Alaska Stas. Prog. Rpt. 1938-41*, pp. 36-39, figs. 2).—A progress report is made of (1) a study to determine whether salmon fed as the sole animal protein portion of the ration for Yukon mink is detrimental to the quality of the fur, followed by (2) the results of a feeding experiment with marten as related to finer fur quality and greater prolificacy, (3) a viability investigation of the internal parasite ova of blue foxes under local conditions, and (4) an investigation of ophthalmia in blue fox pups.

**[Work with fur-bearing animals by the Oregon Station]** (*Oregon Sta. Bul. 401* (1941), pp. 69-71, fig. 1).—The work of the biennium 1939-40 (E. S. R., 82, p. 353) reported upon relates to the establishment of an experimental fur farm, investigation of fox equipment, fox and mink feeding trials, breeding and reproduction investigations, and fur animal disease problems.

**Using fish meal as a partial substitute for raw meat in the year around mink ration, C. F. BASSETT** (*Amer. Fur Breeder*, 15 (1942), No. 3, pp. 12, 14, 16-17, 22).

**Gestation period in the fisher [Martes pennanti], with recommendations for the animal's protection in California, E. R. HALL.** (Univ. Calif.). (*Calif. Fish and Game*, 28 (1942), No. 3, pp. 143-147, fig. 1).

**Biological control of rodents and predators, V. E. SHELFORD.** (Univ. Ill.). (*Sci. Mo.*, 55 (1942), No. 4, pp. 331-341, figs. 3).

**Catalogue of birds of the Americas and the adjacent islands in Field Museum of Natural History, C. E. HELLMAYR and B. CONOVER** (*Field Mus. Nat.*,

*Hist. [Chicago] Pub., Zool. Ser., 13 (1942), pt. 1, No. 1, pp. VI+636*).—Number 1 of the first part of this catalog includes birds of the orders Rheiformes, Tinamiformes, Galliformes, Gruiformes, and Columbiformes.

**Birds benefit Utah agriculture**, G. F. KNOWLTON (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, p. 2, fig. 1).—Attention is directed to the importance of birds in checking insect pests in Utah, particularly the grasshopper and beet leafhopper.

**The ducks, geese, and swans of North America: A vade mecum for the naturalist and the sportsman**, F. H. KORTRIGHT (*Washington, D. C.: Amer. Wildlife Inst., 1942, pp. VIII+476, pls. 36, figs. [270]*).—Descriptive accounts of the life history of these fowl include their weights and measurements. Colored plates of the forms described, with their winter and autumn plumages, by T. M. Shortt, and a bibliography of nine pages are included.

**Cover requirements of the eastern ruffed grouse in northeast Iowa**, E. B. POLDERBOER. (Iowa Expt. Sta. et al.). (*Iowa Bird Life*, 12 (1942), No. 4, pp. 50-55, fig. 1).—It was found in the study reported that for approximately 45 ruffed grouse on 1,414 forested acres in the vicinity of Lansing, Iowa, from August 1938 to January 31, 1940, the following cover types were of greatest utilization value in the order named: Poplar consociations, 10-20-year-old oak-hickory forest, 5-10-year-old clearings, advanced oak-hickory forest, and 20-35-year-old oak-hickory forest. Cover type groups utilized as loafing cover in order of importance were second growth clearings, advanced forest, and mature forest. Most of the roosts found were on the ground. Winter roosts were chiefly under dogwoods in maple-linden communities on north and east slopes when no snow was on the ground. Following heavy snows the preponderance of winter roosts was found in clearings and in second growth oak-hickory communities.

**Ninth and tenth annual reports of the Cooperative Quail Study Association**, H. L. STODDARD (*Coop. Quail Study Assoc. Ann. Rpts., 9-10 (1940-41), pp. 39*).—A further report (E. S. R., 84, p. 783) of the progress of work with quail during the calendar years 1940 and 1941.

**The white-necked raven in relation to agriculture**, S. E. ALDOUS (*U. S. Dept. Int., Fish and Wildlife Serv., Res. Rpt. 5 (1942), pp. II+56, figs. 12*).—The results of a 5-yr. study of the activities and food habits of the white-necked raven (*Corvus cryptoleucus*), during which time field data were gathered and the contents of 827 stomachs were analyzed, are reported. This raven, which is indigenous to southwestern United States and the adjoining sections of Mexico, has gained the same ill repute as acquired by the crow, a close relative, and the magpie. Its omnivorous food habits often bring it into direct competition with farming interests and frequently its depredations result in severe damage to crops, particularly to grain sorghums, corn, melons, peanuts, pecans, weak lambs, and poultry. To reduce these attacks and keep the losses at a minimum often is expensive and requires considerable work and ingenuity on the part of farmers and ranchers. On the other hand nearly half the raven's food is of animal origin and includes a wide assortment of insects, many of which are harmful to crops. Grasshoppers, weevils, May beetles, caterpillars, fly maggots, and like pests constitute a material part of the insect diet. Carrion is another important food of the raven, and its removal from the range is a definite aid to sanitation.

When heavy raven concentrations occur the crops must be protected. As effective control is impossible when natural food is abundant, it is generally necessary to resort to frightening measures until winter sets in and the food supply becomes low enough to insure control success. Various contrivances to scare the birds away may be placed in the fields, but the shotgun is without question the best frightening device. The most successful, selective, and humane control measure

is the use of large cage traps. As the need for control is usually local and varies by seasons, depending upon the crop situation, the soundest policy is to resort to it only when necessary and to take advantage of the bird's better attributes at all other times.

**Notes on the nesting habits of the American robin (*Turdus migratorius* L.),** J. C. HOWELL. (*Amer. Midland Nat.*, 28 (1942), No. 3, pp. 529-603 figs. 5).—This report of a study, based upon field work at Ithaca, N. Y., during a 3-yr. period and a review of the literature, presented with a five-page list of references, includes much data on the feeding and the food of the young.

**Handbook of frogs and toads: The frogs and toads of the United States and Canada,** A. A. and A. H. WRIGHT (*Ithaca, N. Y.: Comstock Pub. Co., 1942, pp. XI+286, pls. 88, figs. 7*).—This work includes a classified bibliography of 37 pages arranged under the headings of general works, general check lists or catalogs, and State and province lists of the political divisions of North America.

**The nematode genus *Skrjabinoptera* Schulz, 1927,** B. B. MORGAN. (Univ. Wis.). (*Lloydia*, 5 (1942), No. 4, pp. 314-319, pl. 1).—Present knowledge of the genus *Skrjabinoptera*, including a discussion of those forms which have not been adequately described, a redescription of one species (*S. phrynosoma*), a world host list, and a key to the species, is presented.

**[Contributions on economic entomology]** (*Ann. Appl. Biol.*, 29 (1942), No. 3, pp. 268-321, figs. 5).—Contributions presented are: Symbiosis and Sirifield Woodwasps, by E. A. Parkin (pp. 268-274); Some Notes on the Biology of the Click Beetles *Agriotes obscurus* L. and *A. sputator* L., by H. C. Gough and A. C. Evans (pp. 275-279); Laboratory and Field Experiments on the Control of Wireworms, by H. C. Gough (pp. 280-289); The Quantitative Interaction of Spray Fluid and Active Principle in Determining the Toxicity of a Pyrethrum Preparation to the Argasid Tick *Ornithodoros moubata* Murray, by G. G. Robinson (pp. 290-300); The Use of Toxic Polynitro Derivatives in Pest Control—I, The Estimation of Dinitro-*o*-cresol and Dinitro-*o*-cyclohexylphenol, by R. L. Wain (pp. 301-308); New Methods of Controlling Head and Body Lice, by J. R. Busvine (p. 309); Experimental Work on the Transmission and Development of Scabies, by K. Mellanby (p. 309); Some Quantitative Aspects of Scabies Parasitology, by C. G. Johnson (p. 310); The Control of Flies in Country and Town, by H. G. H. Kearns (pp. 310-313); Furniture Beetles and Other Wood-Borers, by R. C. Fisher (pp. 313-316); and The Invasion of Houses by Earwigs and Ants, by G. F. Wilson (pp. 316-321).

**[Contributions on economic insects]** (*Assoc. South. Agr. Workers Proc.*, 43 (1942), pp. 127-155).—Abstracts of contributions on economic insects presented at the annual meeting of the Cotton States Branch of the American Association of Economic Entomologists held at Memphis, Tenn., in February 1942 are presented. These relate to the boll weevil, cotton aphid, bollworm, cotton flea hopper, pink bollworm, cotton leafworm, plum curculio on peach, pickleworm, striped blister beetle, sugarcane borer, and stablefly and their control. Other contributions consider methods of rearing *Chelonus* and *Microbracon* parasites; notes on the biology of *Xanthopastis timais* Cramer, a lepidopterous pest of narcissus; and protection of stored grain from insects.

**[Entomological investigations by the Georgia Station]** (*Georgia Sta. Rpt.* 1942, pp. 77-83, figs. 3).—A progress report (E. S. R., 86, p. 806) noting work with the cowpea curculio (coop. S. C. Expt. Sta.); southern corn rootworm; cotton insects; pale-striped flea beetle; the bill bug *Calendra venata* (Say) and a fly (*Neolusioptera* sp.) on wheat; red-headed caterpillar *Stegasta bosqueella* Chamb. on peanut and partridge pea; a weevil (*Conotrachelus* sp.)

and a mealybug, possibly the grape mealybug, on partridge pea; the lesser corn-stalk borer; and the pepper maggot *Zonosemata electa* (Say).

[Entomological investigations by the Kansas Station]. (Partly coop. U. S. D. A.). (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 48-49, 52-56).—A progress report (E. S. R., 85, p. 84) of work by R. K. Nabours, F. M. Stebbins, R. L. Parker, R. C. Smith, R. H. Painter, H. R. Bryson, D. A. Wilbur, P. G. Lamerson, R. W. Jugenheimer, L. P. Reitz, E. G. Heyne, R. F. Fritz, and K. L. Anderson on studies in inheritance of the grouse locust *Tettigidea parvipennis* Har.; effect of climate on inheritance of the grouse locust; bee investigations; climate and injurious insect investigations; the hessian fly, chinch bug, wheat white grub *Phyllophaga lanceolata* Say, and wireworms (*Monocrepidius vespertinus*) on wheat; the corn earworm, southwestern corn borer, chinch bug, sugarcane root-stock weevil, and southern corn rootworm in sweet corn; fruit and vegetable insects (the red spider mite, juniper midge, redbud leafhoppers, redbud aphid, redbud whitefly, and cankerworms); insects attacking alfalfa, grasses, and allied plants; biology and control of the strawberry leaf roller and the codling moth; and the resistance of crop plants to insect attack.

Montana insect pests, 1941 and 1942, H. B. MILLS (*Montana Sta. Bul. 408* (1942), pp. 36, figs. 9).—This biennial report (E. S. R., 84, p. 785) contains information on grasshopper control during 1941-42 and outlook for 1943; Mormon cricket control; stored grain insects; newly introduced insects, including the screwworm and spinose ear tick *Otiobius megnini* Duges; other records and observations with reference to Say stinkbug, corn leaf aphid, potato and tomato psyllid, red-humped caterpillar, diamondback moth, beet webworm, spruce budworm, army cutworm, pale western cutworm, corn earworm, raspberry root borer, raspberry fruitworm, sweetclover weevil *Sitona cylindricollis*, Fahr., pea weevil, bean weevil, plum gouger, plum curculio, seed-corn maggot, *Wohlfahrtia meigeni* (Schin.) maggots in mink pups, cabbage maggot on turnips, wheat stem sawfly, and the European earwig; and the beekeeping industry in Montana.

[Entomological investigations by the Oregon Station]. (Partly coop. U. S. D. A.). (*Oregon Sta. Bul. 401* (1941), pp. 36-37, 40, 50, 51, 52, 53, 54, 57, 58, 59, 62-63, 65-66, 68, figs. 9).—A progress report of the biennium 1939-40 (E. S. R., 82, p. 355) noting control of prune thrips, control of rust mite on pears, control of the cherry fruitfly, alfalfa weevil, pea aphid control, flax worm, potato flea beetle, onion maggot, symphylids, pea weevil, insect pests of nursery stock, and the filbert worm.

Supplement to Insects of North Carolina, C. S. BRIMLEY (*Raleigh: N. C. Dept. Agr., 1942*, pp. 39).—This supplement to the work noted (E. S. R., 80, p. 307) increases the number of species recorded from the State by 791 and near insects by 52, or a total of 843, bringing the grand total for the State to 11,091 on December 31, 1941.

[Entomological investigations by the Puerto Rico Station]. (Partly coop. U. S. D. A. et al.). (*Puerto Rico Sta. Rpt. 1941*, pp. 19-23).—A progress report (E. S. R., 87, p. 694), by K. A. Bartlett and H. K. Plant, noting liberations of the São Paulo strain of the Amazon fly *Metagonistylum minense* Towns. and shipments to Louisiana and Guadeloupe; receipt of shipments of *Paratheresia diatraca* (Bréthes), a fly parasite of the sugarcane borer, and liberations of and shipment to Cuba; establishment of *Coclophora inaequalis* (F.), a coccinellid predator of aphids, and *Pseudaphycus utilis* Timb., a hymenopterous parasite of the coconut mealybug; control of the bamboo scales (*Asterolecanium bambusae* (Bdv.) and *A. miliaris* (Bdv.)) and other scales through use of the introduced coccinellid predators *Egys platycephalus* Muls., *Chilocorus cacti* L., *Pentilia castanea* Muls., *Cladis nitidula* F., and *Curinus* sp.; receipt of

shipment of dipterous parasites (*Ectophasiopsis arcuata* (Bigot) and *Cylindromyia porteri* (Br  thes)) of various species of pentatomids; rearing and liberation of *Dasyiscapus parvipennis* Gahan, a parasite of the red-banded thrips; the bamboo powder-post beetle *Dinoderus minutus* (F.); control work with the mining scale and hemispherical scale; injury to vanilla plantings by the snail *Subulina octona* Brug and the slug *Veronicalla kraussii* Ferussac; the bean aphid and *Macrosiphum sonchi* (L.) on the orange-glowvine (*Senecio confusus*); and control of the dry-wood or powder-post termite *Kaloterms* (*Cryptoterms*) *brevis* (Walker).

Some applications of insect separation methods to entomology, K. L. HARRIS (*Ent. Soc. Wash. Proc.*, 45 (1943), No. 1, pp. 19-25, fig. 1).

Studies on the hydrogen-ion concentration of insect blood and their bearing on in vitro cytological technique, R. D. BOCHE and J. B. BUCK (*Physiol. Zool.*, 15 (1942), No. 3, pp. 293-303).—Measurements by capillary glass electrode of the H-ion concentration of the larval blood of three species of Diptera give the following average results: *Drosophila melanogaster* pH 7.10, *Sciara coprophila* pH 7.12, and *Chironomus tentans* pH 7.48. Microquinhydrone electrodes, considered somewhat less reliable, give the values pH 7.12 for *Drosophila* and pH 7.38 for *Sciara*. Critics of the methods and the variability of blood H-ion concentration are presented. A table summarizing most of the existing literature on the H-ion concentration of insect blood is included.

Insects of the garden bean in Hawaii, F. G. HOLDAWAY and W. C. LOOK. (Hawaii Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 11 (1942), No. 2, pp. 249-260).—The first of a series of articles dealing with insects of crops other than sugarcane and pineapple in Hawaii. The relative importance of the insects has been recorded and the major pests determined. Eight major, 3 submajor, and 23 minor pests and 22 species of beneficial insects are recorded. The major pests have been classified on an ecological basis.

Some insect pests of lilies, E. P. IMLE and A. HARTZELL. (Cornell Univ. et al.). (*Amer. Lily Yearbook*, 1942, pp. 42-47, figs. 4).

Insects infesting house plants.—I, Scale insects, E. I. McDANIEL (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 121-125, figs. 2).—A practical account.

The forests insect situation in eastern Canada in 1941, E. B. WATSON (*Canad. Pulp and Paper Assoc., Woodlands Sect., Ann. Mtg. Proc.*, 24 (1942), p. 42).

Insect pests in stored products, H. HAYHURST (*London: Chapman & Hall*, 1942, 2. ed., pp. XII+108, pls. [55]).—Included in this brief practical account is a list of the substances and their pests (pp. 59-83), list of parasitic and predaceous insects and their hosts (p. 84), a bibliography (pp. 85-105), and a subject index (pp. 106-108).

Rearing fabric pests, F. W. FLETCHER and E. E. KENAGA (*Soap and Sanit. Chem.*, 18 (1942), No. 9, pp. 92-93, 101).—In tests of 10 mixtures composed of varying proportions of fish meal, dog food, corn meal, brewer's yeast, and woolen scraps to determine the most desirable food medium for rearing the black carpet beetle, a culture consisting of 72 percent fish meal, 25 percent corn meal, 3 percent brewer's yeast, and 2 gm. of woolen cloth proved the most satisfactory. Three other food mixtures were acceptable.

Mothproofing tests, F. W. FLETCHER and E. E. KENAGA (*Soap and Sanit. Chem.*, 18 (1942), No. 8, pp. 95-99, fig. 1).—Report is made of cooperative research work aimed at standardization of a procedure for testing fabric insect pest deterrents. A quantitative test employing use of the weight of the frass as a measure of the resistance of fabrics to the pests was used, and the procedure

was later compared with the fabric weight loss method for determining fabric pest resistance. Details of the findings are given in five tables.

**Biological control of insects in Canada**, A. B. BAIRD (*Amer. Pomol. Soc. Proc.*, 56 (1941), pp. 111-117).

**Control of destructive insects by aircraft**, W. E. DOVE (*Sci. Mo.*, 55 (1942), No. 4, pp. 382-386, figs. 5).

**The war program and the part which insecticides and disinfectants are playing in it**, J. E. DUNN, P. A. SURGEON, and L. SCHWARTZ (*Soap and Sanit. Chem.*, 18 (1942), No. 8, pp. 91-94, 105).—Presented with a list of 21 references to the literature.

**Some recent advances in insecticides**, R. H. MARLOWE. (U. S. D. A.). (*Hawaii. Ent. Soc. Proc.*, 11 (1942), No. 2, pp. 177-194).—This review is presented with a list of 129 references to the literature cited.

**Chemistry of insecticides and fungicides**, D. E. H. FREAR (*New York: D. Van Nostrand Co.*, 1942, pp. VIII+300, figs. 31).—The subject is dealt with as follows: Stomach poisons or protective insecticides (pp. 5-49), contact poisons or cradicant insecticides (pp. 51-150), fungicides (pp. 151-177), spray supplements and residue removal (pp. 179-205), and analytical methods (pp. 207-277).

**Particle size in relation to insecticide efficiency**, C. M. SMITH and L. D. GOODHUE. (U. S. D. A.). (*Indus. and Engin. Chem.*, 34 (1942), No. 4, pp. 490-493, figs. 4).

**Observations on the automatic distribution of paris green**, F. W. KNIPE and P. F. RUSSELL (*Amer. Jour. Trop. Med.*, 22 (1942), No. 4, pp. 447-457, figs. 4).—The automatic distribution of paris green for the control of *Anopheles* breeding along irrigation canal banks is reported upon. Two modifications of the original automatic paris green distributor are described. One is an improved machine for using paris green diluted with dust, such as powdered charcoal. The other is for dustless paris green in a water suspension. The modified machine for distribution of dust was given thorough field trials and performed satisfactorily, with effective larva control. The other machine had fewer trials but seemed to function well.

**Preparation of pure geraniol**, H. A. JONES and J. W. WOOD. (U. S. D. A.). (*Indus. and Engin. Chem.*, 34 (1942), No. 4, p. 488).

**Needed: A substitute for pyrethrum**, C. A. DOEHLERT. (N. J. Expt. Stas.). (*Amer. Cranberry Growers' Assoc., Proc. Ann. Conv.*, 73 (1942), pp. 19-23).—The need of a substitute for pyrethrum led to tests which have shown the synthetic compound Lethane to have a definite lethal effect on the adult bluntnosed leafhopper *Ophiola striatula* Fall. While the percentage of kill by Lethane was not as high as with pyrethrum it may prove to be sufficiently toxic to control the nymphs. There appeared to be a progressive resistance of adult leafhoppers from July 14 to August 12. Mixing 9 parts of talc to 1 of pyrethrum and using it at a rate corresponding to 75 lb. per acre produced very good kills. Lethane did not increase the effectiveness of pyrethrum to any notable extent. DN dust (a dinitro-o-cyclohexylphenol dust) may be as effective as Lethane.

**Increased toxicity with rotenone dusts**, E. J. CAMPAU, H. F. WILSON, and R. L. JANES (*Soap and Sanit. Chem.*, 18 (1942), No. 8, pp. 100-101, 103).—The percentage of control obtained in 24 hr. in tests made of a series of chemicals, compared to determine their possible value as adjuvants in rotenone dusts (with and without SAE10 lubricating oil) in which 0.1 percent rotenone was used, is compared with the results of similar experiments with rotenone dusts (with and without the oil) in which 0.05 percent rotenone was employed. The results indicate that under these conditions consistent increased control with low concentrations of rotenone is obtained.

**Reclamation with rotenone of Crystal Lake, Los Angeles County, California.** E. H. VESTAL (*Calif. Fish and Game*, 28 (1942), No. 3, pp. 136-142, figs. 4).—The successful reclamation with rotenone from pest fish (chub)-infested Crystal Lake in the Angeles National Forest, Los Angeles County, is reported upon.

**Tephrosia extract against house flies.** H. A. JONES and W. N. SULLIVAN (U. S. D. A.). (*Soap and Sanit. Chem.*, 18 (1942), No. 9, pp. 94-95).—The tests reported have shown that the domestic plant *T. virginiana* may be successfully substituted for derris and cube roots in fly sprays. The work also indicates that no added solvent is necessary to obtain kerosene extracts of rotenone-bearing roots with a high degree of toxicity to houseflies. The insecticidal importance of constituents other than rotenone is again emphasized.

**Preventing damage to buildings by subterranean termites and their control** (U. S. Dept. Agr., *Farmers' Bul.* 1911 (1942), pp. [2]+37, figs. 31).—A practical account which supersedes Farmers' Bulletin 1472 (E. S. R., 55, p. 152) and Leaflet 101 (E. S. R., 70, p. 209).

**Studies of North American Plecoptera, with special reference to the fauna of Illinois.** T. H. FRISON (*Ill. Nat. Hist. Survey Bul.*, 22 (1942), Art. 2, pp. [4]+235-355, figs. 127).—A report of studies in which 85 forms are recognized, 23 being described as new to science.

**A study of riboflavin metabolism in the American [cock]roach by fluorescence microscopy.** R. L. METCALF and R. L. PATTON. (Cornell Univ.). (*Jour. Cell. and Compar. Physiol.*, 19 (1942), No. 3, pp. 373-376).

**Forecasts of incipient outbreaks of the brown locust [*Locustana pardalina* (Walk.)],** C. J. B. SMIT (*Jour. Ent. Soc. South. Africa*, 4 (1941), pp. 206-221).

**The acarine parasites of South African acridids, with special reference to the genus *Podapolipus*.** M. LAVOPIERRE (*Jour. Ent. Soc. South. Africa*, 4 (1941), pp. 71-80, figs. 5).—A summary of the knowledge of acarine parasites infesting locusts in South Africa.

**The potato leafhopper, a pest of alfalfa in the Eastern States.** F. W. POOS (U. S. Dept. Agr. Leaflet 229 (1942), pp. 8, figs. 3).—A practical account.

**A taxonomic revision of the genus *Eutettix* in America north of Mexico (Homoptera: Cicadellidae).** L. W. HEFNER (*Kans. Univ. Sci. Bul.*, 28 (1942), No. 2, pp. 253-294, pls. 3).—Thirty forms of leafhoppers of the important genus *Eutettix* are considered, of which 18 are described as new to science.

**The food and feeding habits of *Antestia* in Kenya.** R. H. LE PELLEY (*Bul. Ent. Res.*, 33 (1942), No. 2, pp. 71-89, pls. 2, fig. 1).—Report is made of studies of *A. lineaticollis* in Kenya, where, in addition to *Coffea arabica*, *Psychotria nairobiensis* and *Pavetta elliotii* are known as host plants.

**Avoid residue in tomato psyllid treatment.** G. M. LIST. (Colo. Expt. Sta.). (*Canning Age*, 23 (1942), No. 8, p. 431).

**A simple method for use in staining living aphids.** R. P. GORHAM (*Canad. Ent.*, 74 (1942), No. 12, p. 236).

**Systema Aphididae: A guide to the phylogeny of the aphids or plant lice.**—I, The Lachnea, O. W. OESTLUND (*Rock Island, Ill.: Augustana Book Concern*, [1942], pp. V+78).

**Some experiments on the sugarcane mealybug *Trionymus* (*Pseudococcus*) *sacchari* Kll.,** J. DICK (*So. African Sugar Technol. Assoc., Ann. Cong. Proc.*, 16 (1942), pp. 55-56, fig. 1).—A brief report of preliminary experiments that emphasize the danger of planting sugarcane sets infested by mealybugs due to the harmful effect on germination and subsequent growth.

**Life-history and bionomics of *Pseudococcus saccharicola* Takh. (Homoptera: Pseudococcidae), a new pest of sugarcane in India.** S. RAM MOHAN RAO (*Indian*

*Acad. Sci. Proc.*, 16 (1942), No. 3, Sect. B, pp. 79-85).—Included in this account of a new pest of sugarcane in India are notes on its predators and parasites.

**Fumigation in red scale control**, D. L. LINDGREN. (Calif. Citrus Expt Sta.). (*Calif. Citrog.*, 27 (1942), No. 11, pp. 308-309, 324).

**Systematics of the meloid genera *Hornia* and *Allendesalazaria* (Coleoptera)**, E. G. LINSLEY (*Calif. Univ. Pubs. Ent.*, 7 (1942), No. 8, pp. 169-187, pls. 2, figs. 2).

**Recent progress in wireworm control**, J. A. MUNRO and H. S. TELFORD (*North Dakota Sta. Bimo. Bul.*, 5 (1942), No. 2, pp. 7-11, figs. 3).—A progress report, with special reference to the prairie grain wireworm *Ludius acreipennis* destructor Brown, which notes the general life cycle of this pest as well as recommendations for control, with particular emphasis on clean summer fallow, rotations, proper varieties for least injury, time of planting, and selection of most suitable fields.

**The grape rootworm**, D. ISELY (*Arkansas Sta. Bul.* 426 (1942), pp. 26, figs. 5).—This insect is the most destructive pest of grapes in Arkansas. Adults feed on foliage and green berries. Larvae feed on sapwood of larger roots and destroy small roots. Vine vigor is reduced because of girdling. Eggs are deposited from June to August in flattened clusters on the canes under bark strips, and upon hatching the larvae drop and burrow into the soil. Some become fully grown before winter, which is passed by these larvae at depths of a few inches to nearly 2 ft. The majority renew feeding in the spring, apparently requiring a second year for development. Pupation takes place largely in May, and adults begin to emerge from the soil shortly thereafter. Adults may be destroyed during the preoviposition period of about 2 weeks with one or two grape foliage sprays of 1.5 lb. of derris powder (containing 4 percent of rotenone) in 50 gal. of water. An application of 1.5 lb. of lead arsenate in 50 gal. of water or in bordeaux mixture, which is usually made to control other vineyard pests, is effective for the control of light infestations.

**Progress in pine beetle control through tree selection**, F. P. KEEN and K. A. SALMAN. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 11, pp. 854-858).—The method of western pine beetle control through removal of high risk trees from the stand is considered. A description is given of the various tree classifications that have been proposed and their application to bark beetle control.

**The biology and natural control of the larch-shoot moth *Argyresthia laevigatella* H.-S.**, B. P. BEIRNE (*Roy. Dublin Soc. Econ. Proc.*, 3 (1942), No. 11, pp. 130-149, figs. 28).—Report is made of an investigation of the biology and natural control in Ireland of *A. laevigatella*, which causes a considerable amount of damage annually throughout Europe and the British Isles. Insectivorous birds are said to be the most important factor in natural control in Ireland, destroying an average of 67 percent of the larvae and pupae. A further 10 percent are destroyed by fungi, nematodes, hymenopterous parasites, and other factors. *Ephialtes* (*Pimpla*) *elegans* Woldst., the only hymenopterous parasite reared on the larva of this parasite, averaged a destruction of 1 percent. A general account of the systematics, synonymy, distribution, life history, and biology of *E. elegans* is given, with descriptions of the morphology of the early stages. A list of 21 references to the literature is included.

**Owlet moths (Phalaenidae) taken at light traps in Kansas and Nebraska**, H. H. WALKDEN and D. B. WHELAN. (Coop. Nebr. Expt. Sta.). (*U. S. Dept. Agr. Cir.* 643 (1942), pp. 26, figs. 11).—Approximately 90 percent of the owlet moths taken in light traps in six localities during the period 1934-37 were of economic importance. Sex ratio varied greatly with the species. Although the numbers of moths taken differed greatly in the separate localities, from year to year and time of year when the greatest period of flight occurred, the flights of indi-

vidual species showed the same trend in all localities. Species with a single generation per year had a short flight period, usually from late August to early October. Flights of different generations of multiple-generation species were not clearly defined.

**Biología de la Laspeyresia molesta en el Uruguay [Biology of the oriental fruit moth in Uruguay]**, R. J. AMABILE ARANDA (*Univ. Repub. [Montevideo]*, *Rev. Facult. Agron.*, No. 27 (1942), pp. 137-166, figs. 30).

**The calyx spray in codling moth control**, D. B. WADDELL and J. MARSHALL (*Sci. Agr.*, 22 (1942), No. 7, pp. 413-418).—In laboratory investigations in British Columbia the "first instar codling moth larvae, when penetrating the calyx cavity a month or more subsequent to petal fall, chewed very little on the inner parts of the calyx but did so fairly extensively on the sepals. A calyx spray of lead arsenate applied by a spray gun when 90 percent of the petals had fallen was found to be fairly effective in preventing the entry of codling moth larvae at the calyx a month later. Three mo. after application the calyx treatment still showed distinct value. An angle nozzle on a bamboo rod, used from spray tank as well as ground, deposited no more spray on the calyx parts than a single nozzle spray gun used from the ground alone, although the operation required three times as long." The functions of the calyx spray as now applied in that province appear to be to deposit poison on the inner surfaces of the sepals, to insure protection before the earliest first generation larvae are hatched, and to act as a basis for later sprays and so contribute to a maximum deposit when attack of first generation larvae becomes general. Application of the calyx spray for codling moth control in that province appears to be sound practice, though there seems no reason to believe that in applying that spray it is essential to force spray material into the inner calyx cavity.

**Varietal interplanting in relation to control of the codling moth**, R. I. NEL (*Jour. Ent. Soc. South. Africa*, 4 (1941), pp. 111-134, figs. 9).—A study was made of the trends of production of codling moth larvae in pear varieties in two orchards of different varietal composition by the banding method, considered to be more accurate for this purpose than the "exit-hole" method. The time that first-brood larvae attained maturity varied according to variety, there having been differences of from 2 to 3 weeks with respect to the periods of peak larval production between the varieties Clapp Favorite and Beurre Hardy and of lesser periods among other varieties. The succession in time of larval production appears to follow the order of blossoming, and there is apparently a close relation between blossoming and egg laying. Differences were recorded between varieties as regards the total extent of larval contribution and the relative production of first- and of summer-brood larvae. The main factors that influence varietal infestation and larval production in orchards, i. e., the seasonal level of codling moth activity, the time and period of availability of fruit, varietal attractiveness for egg laying, and varietal resistance to infestation, are discussed. The influence of various varietal types on population build-up through the season and on the carry-over of the pest from one season to the other is analyzed. A list of 26 references to the literature is included.

**Ear worm control in sweet corn**, C. T. SCHMIDT. (*Univ. Hawaii*). (*Hawaii. Ent. Soc. Proc.*, 11 (1942), No. 2, pp. 195-197, fig. 1).—In experimental work the use of white mineral oils either alone or with the addition of rotenone in the form of derris extract gave a satisfactory control of the corn earworm when applied to the wilted silks with a mechanic's oiler. Damage to the extent of 10.6 percent occurred where oil alone was used and 6.2 percent where derris extract was added, as compared to 60.8 percent in the untreated checks.

**A tachinid parasitic on *Plutella maculipennis* Curt., F. I. VAN EMDEN** (*Bul. Ent. Res.*, 33 (1942), No. 4, pp. 223-225, fig. 1).—A tachinid reared from the diamondback moth in Nairobi is described as new under the name *Cadurcia plutellae*.

**Host plants and parasites of some lepidopterous larvae, W. L. PUTMAN** (*Canad. Ent.*, 74 (1942), No. 12, pp. 219-224).—These data supplement the earlier contribution (E. S. R., 73, p. 655).

**Notes on some lepidopterous pests on fruit trees, and their parasites, in Ireland during 1941, B. P. BEIRNE** (*Roy. Dublin Soc., Econ. Proc.*, 3 (1942), No. 9, pp. 107-118, figs. 9).

**Lepidopterous pests of maize in Trinidad, H. B. N. HYNES** (*Trop. Agr. [Trinidad]*, 19 (1942), No. 10, pp. 194-202, figs. 2).

**Biology and control of mosquitoes in the rice area, W. R. HORSFALL** (*Arkansas Sta. Bul.* 427 (1942), pp. 46, figs. 4).—Two flood-water and two permanent-water species of noxious mosquitoes constituted from 98 to 99 percent of the population on Grand Prairie in Arkansas County. *Psorophora confinnis* (L.-A.) and *P. discolor* (Coq.) of the former group make up from 83 to 94 percent of the light-trap collections, while the common malaria mosquito and *Culex erraticus* D. and K. account for the remainder. *P. confinnis* occurs from mid-May until early September, with one peak appearing the latter half of June and the other in late July and throughout August. Growing soybeans or leaving the land idle the season before rice is an effective means for reducing numbers of this species. Applying a miscible oil at the rate of 4 p. p. m. is a means of direct chemical control. The common malaria mosquito is most active from early June until late September. During two of three seasons larvae were most numerous in rice fields from mid-June until mid-July. *Anopheles* larvae occurred most abundantly in open water in rice fields. Isolation, drainage, oiling, and treatment with paris green, as well as the use of top-water minnows of the genus *Gambusia*, are useful control measures.

**The mosquitoes of Oklahoma, L. E. ROZEBOOM** (*Oklahoma Sta. Tech. Bul.* 16 (1942), pp. 56, figs. 81).—Of the 40 species reported, 13 belong to the genus *Aedes*, 5 to *Anopheles*, 7 to *Culex*, 9 to *Psorophora*, 2 to *Theobaldia*, and 1 each to *Mansonia*, *Megarhinus*, *Orthopodomyia*, and *Uranotaenia*. Breeding places, seasonal and relative abundance, and larval associations of Oklahoma mosquitoes are discussed. Keys are included for use in the determination of females, males, and larvae, and supplemented by 78 photomicrographs. Notes on each species mention recognition characters, distribution, and habits. Mosquito control is briefly discussed and a selected list of references included.

**The anopheline mosquitoes of the Caribbean region, W. H. W. KOMP** (*U. S. Pub. Health Serv., Natl. Inst. Health Bul.* 179 (1942), pp. IX+195, figs. 155).—A summary of the present knowledge of the anopheline mosquitoes of the Caribbean region based upon examination of the literature and personal observations by the author. It deals with their known geographic distribution and status as vectors of malaria but more particularly with their classification and identification. The account is written primarily from the point of view of the systematic entomologist, but the needs of the field man engaged in malaria control have been kept in mind. For this reason there have been incorporated numerous illustrations and keys, the latter in both Spanish and English, together with a list of entomological terms in English, Spanish, and Portuguese for the convenience of Latin-American workers. Included are brief notes on habitat, distribution, and relative commonness of the species, of which 22 are recognized.

**Synoptic tables for the identification of the full-grown larvae of the Indian anopheline mosquitoes, I. M. PURI ([India] *Health Bul.* 16 (*Malaria Bur. No.* 7), 4. ed. (1941), pp. [9]+109, figs. 84).**

**Notes on improvements made to equipment for spray-killing of adult mosquitoes, F. W. KNIPE and N. R. SITAPATHY (*Amer. Jour. Trop. Med.*, 22 (1942), No. 4, pp. 429-446, figs. 10).**—A description is given of improvements in six types of equipment for use in malaria control by spray-killing adult mosquitoes in rural areas.

**The utilisation of waste lubricating oil in mosquito larvicides, W. A. L. DAVID (*Bul. Ent. Res.*, 33 (1942), No. 4, pp. 235-240).**—Examination was made of nine samples of waste oils, the suitability of which as larvicides was determined after blending with kerosene and diesel oil. It was concluded that blends containing 25-30 percent of waste oil are not so effective as an approved commercial larvicide at the same dosage, but that with a higher dosage, which is still within the range commonly applied in the field, i. e., between 4 fluid oz. and 6.7 oz. per 100 sq. ft., they give good results. The higher dosage is only necessary when culicine larvae have to be controlled. Other blends containing 10-20 percent of waste oil are as effective as an approved commercial sample.

**[Contributions on anopheline mosquitoes and their control] (*Jour. Natl. Malaria Soc.*, 1 (1942), pp. 5-24 45-55, 69-124, 149-162, figs. 47).**—Among the contributions presented are the following: Species Eradication—A Practical Goal of Species Reduction in the Control of Mosquito-Borne Disease, by F. L. Soper and D. B. Wilson (pp. 5-24); The Crushing Strength of Biological Films on Natural Waters and the Spread of Larvicidal Oils, by C. E. Renn (pp. 45-55); Circular Joint and Concrete Form Design for Precast Inverts for Malaria-Control Ditch-Lining, by W. A. Legwen and L. G. Lenert (pp. 69-82); The Design and Application of a New Type Automatic Siphon for Malaria Control, by W. A. Legwen and R. S. Howard, Jr. (pp. 83-92); Studies on Artificial Resting Places of *Anopheles quadrimaculatus* Say, by M. H. Goodwin, Jr. (pp. 93-99); Studies on the Choice of a Medium for Oviposition by *Anopheles quadrimaculatus* Say, by H. O. Lund (pp. 101-111); Review of Recent Publications on the Prophylaxis and Treatment of Malaria, by H. C. Clark (pp. 113-124); A Review of Recent Work in Avian Malaria, by M. D. Young (pp. 149-156); and Entomological Work During 1941 Bearing on the Malaria Problem, by S. J. Carpenter, T. T. Brackin, Jr., and D. F. Ashton (pp. 157-162).

**Manual for the microscopical diagnosis of malaria in man, A. WILCOX (*U. S. Pub. Health Serv., Natl. Inst. Health Bul.* 180 (1942), pp. IX+39, pls. 13).**

**Madiza: A chloropid or a milichiid (Dipt.)? (C. W. SABROSKY. (Mich. Expt. Sta.). (*Ent. Mo. Mag.*, 4. ser., 3 (1942), No. 32, pp. 169-171).**—The proper classification of some flies common to both Europe and North America is reviewed.

**The activity of the Mediterranean fruitfly at cold temperatures, with reference to its status during the citrus season in Palestine, E. RIVNAY (*Jour. Ent. Soc. South. Africa*, 4 (1941), pp. 166-176, figs. 5).**—Laboratory observations indicate that at a temperature of 10°-13° C. most of the Mediterranean fruitflies do not move about, that lively activity does not take place at a temperature below 16°, and that this fruitfly does not oviposit at a temperature below 16° and at a relative humidity above 85 percent. Breeding of flies in cages hung on trees and observations of their activity indicate that no oviposition takes place on rainy days or when the average daily temperature is below 16°. Records taken in the grove on oviposition show no oviposition of any importance in the latter part of November 1940, and that stung oranges may be infested again and again throughout the period of oviposition in oranges.

**Effect of temperature on recovery of houseflies, C. EAGLESON.** (U. S. D. A.). (*Soap and Sanit. Chem.*, 18 (1942), No. 6, pp. 115-117, 141, figs. 4).—The failure, in ordinary use, of pyrethrins and Lethane (beta-butoxy-beta'-thiocyanodethylether) to kill all of the houseflies that are stupefied led to the investigation of the effect of temperature on recovery from the effects of these toxicants. Equations and graphs are presented which show the recovery from applications of pyrethrins and from Lethane administered at temperatures ranging from 22° to 38° C. Temperature was shown to exert less influence on the recovery of houseflies sprayed with Lethane than on that of flies sprayed with pyrethrins. It is concluded from the recovery curves that these toxicants are like narcotics in their action and in order to insure death must be administered in doses considerably stronger than necessary to produce complete torpor.

**The common housefly (*Musca domestica*) as a source of pollution in food establishments, M. OSTROLENK and H. WELCH** (*Food Res.*, 7 (1942), No. 3, pp. 192-200, figs. 3).—In the studies reported, presented with a list of 23 references to the literature, washings from the surface of flies contained from 2,500,000 to 29,500,000 bacteria per fly. Colon-aerogenes bacteria are present in amounts representing 84,000 to 2,000,000 bacteria, *Escherichia coli* being present in considerably reduced numbers. The incidence of colon-aerogenes bacteria externally and internally was found to depend largely upon the material on which the flies are fed. The methods employed in rearing and examining flies in the laboratory are described.

**The parasitic habits of *Muscina stabulans* Fabricius, C. H. CURRAN** (*Jour. N. Y. Ent. Soc.*, 50 (1942), No. 4, pp. 335-336).—The data presented indicate that the false stablefly may be predaceous and yet at times parasitic on other insects.

**New species of *Anastrepha* and notes on other (Diptera: Tephritidae), A. STONE.** (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 32 (1942), No. 10, pp. 298-304, figs. 14).—This contribution, supplementing the author's revision of the genus *Anastrepha* previously noted (E. S. R., 36, p. 661), presents descriptions of seven additional species and additional information on others.

**The fleas of North America: Classification, identification, and geographic distribution of these injurious and disease-spreading insects, H. E. EWING and I. FOX** (*U. S. Dept. Agr., Misc. Pub. 500* (1943), pp. 143, figs. 13).—A revision of the North American genera and of the higher categories of the world is given, including keys and formal descriptions. For species, subspecies, and varieties formal descriptions have usually been supplanted by informal remarks on identification characters, but in all cases the following data have been given: Indication of synonymy, scientific and common name of type host, type locality, and a statement relative to range. Usually also further information has been added relating to the nature of the original description, references to figures, published or new notes on biology, economic importance, and redescriptions. Following the introduction there is a short discussion of the economic importance of fleas and a consideration of the external morphology of the group and its origin and phylogenetic relationships. The taxonomic part proper is followed by a list of synonyms of the North American species and subspecies, a bibliography of 91 references, and a taxonomic index. In this paper 61 genera, 14 subgenera, 209 species, and 63 subspecies and varieties of fleas are listed from North America and the West Indies.

**Nosema apis in package bees, J. F. REINHART** (*Amer. Bee Jour.*, 82 (1942), No. 12, p. 516)

**Nosema disease contributes to winter losses and queen supersedure**, C. L. FARRAR. (U. S. D. A. coop. Univ. Wis.). (*Gleanings Bee Cult.*, 70 (1942), No. 11, pp. 660-661, 701).

**The ants of Utah**, A. C. COLE, JR. (Univ. Tenn.). (*Amer. Midland Nat.*, 28 (1942), No. 2, pp. 358-388, figs. 5).

**Red scale parasites: Comparison of oriental races of *Comperiella bifasciata* in California**, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 28 (1943), No. 3, p. 78).

**Glyptometopa Ashmead and related genera in the Brachycistidinae, with descriptions of new genera and species (Hymenoptera: Tiphidae)**, C. E. MICKEL and K. V. KROMBEIN. (Minn. Expt. Sta.). (*Amer. Midland Nat.*, 28 (1942), No. 3, pp. 648-679, figs. 21).—Seven genera are erected and 12 species described as new to science.

**Preliminary notes on the natural control of the European spruce sawfly by small mammals**, R. F. MORRIS (*Canad. Ent.*, 74 (1942), No. 11, pp. 197-202).—Attention is called to the importance of small mammals as factors in the natural control of destructive forest insect pests. "In eastern Canada it is common to find as high as 40- to 50-percent control of the European spruce sawfly effected under epidemic conditions by small forest mammals. The cinereous shrew, the red-backed vole, and the white-footed mouse are the most abundant mammals in the coniferous forests of this region, the cinereous shrew being the most effective in sawfly control. Population studies show that there is a considerable seasonal fluctuation in the population of small mammals. The character of the site has an important influence on the population of shrews and rodents, dry sites with abundant protective ground cover being preferred. Little insect control by mammals can be expected in stands which have suffered the burning of brush or other 'clean-up' procedures. The activity of small mammals in searching for sawfly cocoons is greatest in the fall, when the mammal population is high and the hoarding of cocoons is a common practice. The searching ability of small mammals is remarkably high. The shrews, but not the rodents, have the ability of recognizing sound cocoons before they open them."

**Sawfly infestations in Pennsylvania**, H. C. WILL (*Pa. Acad. Sci. Proc.*, 16 (1942), pp. 47-51, figs. 4).—The sawfly infestations noted in this contribution include *Arge macleayi* (Leach) on the hazelnut at Bedford, Pa., the azalea sawfly *Amauronematus azaleae* Marlatt in a greenhouse at Collingdale, and the red-headed pine sawfly on seedling pines used for reforestation purposes.

**The brown dog tick, an important house pest, known scientifically as *Rhipicephalus sanguineus* (Latr.)**, F. C. BISHOPP. (U. S. D. A.). (*Pests*, 10 (1942), No. 9, pp. 6-8, figs. 8).

***Ixodes baergi*, a new species of tick from Arkansas (Acarina: Ixodidae)**, R. A. COOLEY and G. M. KOHLS (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 49, pp. 1869-1872, figs. 3).—A tick, apparently parasitic on the cliff swallow, is described as new under the name *I. baergi*.

**Notes on the seasonal history of the rabbit tick (*Haemaphysalis leporis-palustris*) in Oklahoma**, G. W. EDDY. (Okla. A. and M. Col.). (*Ent. Soc. Wash. Proc.*, 44 (1942), No. 7, pp. 145-149, fig. 1).

**Ornithodoros ticks as a medium for the transportation of disease agents**, R. R. PARKER (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 52, pp. 1963-1966).

**The relative toxicity of rotenone and pyrethrum in oil to the argasid tick *Ornithodoros moubata* Murray** G. G. ROBINSON (*Bul. Ent. Res.*, 33 (1942), No. 4, pp. 273-281, figs. 3).—Coal tar phenols were found to be useful intermediate solvents for making solutions of rotenone in both mineral and vegetable oils.

Medium petroleum oil showed superiority to peanut oil as a carrier of rotenone in xyleneol tested against *O. moubata*. The solutions of rotenone in xyleneol and oil showed no deterioration after storage in the dark at room temperature for 6 weeks. In these solutions rotenone proved far less toxic to *O. moubata* than an equal weight of pyrethrin I in medium petroleum oil.

**The tropical chigoe in California**, G. F. AUGUSTON (*Science*, 96 (1942), No. 2504, p. 581).—The chigoe, a tropical and subtropical siphonapterous pest also commonly known as chigger, jigger, or sand flea, is reported as found infesting a Pacific horned owl (*Bubo virginianus pacificus*) at Oceanside, San Diego County. This is said to be the first record of the collection of the adult in the continental United States aside from a single case at New Orleans, La.

**Experiments on the survival and behaviour of the itch mite *Sarcoptes scabiei* DeG. var. *hominis***, K. MELLANBY, C. G. JOHNSON, W. C. BARTLEY, and P. BROWN (*Bul. Ent. Res.*, 33 (1942), No. 4, pp. 267-271).—In this work, the details of which are given in tables, adult female *Sarcoptes* were killed by 120° F. in 10 min. and by 117.5° in 30 min. At 82° no *Sarcoptes* survived for 2 days, and the majority died in 24 hr. At 55° and 90 percent relative humidity the majority of the mites died within a week, but a few survived longer, even up to 14 days. At temperatures below 55° the mites survived for a shorter time. *Sarcoptes* gives no reactions, positive or negative, to unidirectional light. Below 59° *Sarcoptes* is in chill coma. Little movement occurs below 68°. In temperature gradient mites seldom, if ever, go below 75°. They will walk into high temperatures which prove rapidly lethal.

**Some notes on the taxonomy of grain mites (Acarina: Acaridae, formerly Tyroglyphidae)**, H. E. EWING and H. H. S. NESBITT (*Biol. Soc. Wash. Proc.*, 55 (1942), pp. 121-124).

## ANIMAL PRODUCTION

[Experiments in livestock production by the Bureau of Animal Industry.] (Partly coop. expt. stas. et al.) (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1942, pp. 7-8, 9-10, 11-12, 13-15, 15-16, 17-18).—In continuation of previous investigations (E. S. R., 86, p. 662), progress is briefly reported on investigations of quality of beef produced on cottonseed meal and hulls; the influence of the ratios of concentrates to lespedeza hay on beef finish and quality; relation of curing temperature and pumping to salt absorption and spoilage by ham; storage temperature and tenderness of lamb; relation of separable fat from lamb carcasses to grade; heat disposal and tolerance in cattle; mineral deficiencies in cattle; vitamin A deficiencies in fattening cattle; relation of yellow corn storage to vitamin A deficiency; sweetpotato pulp for steers; creep feeding calves on reed pasture; grazing and dry-lot feeding beef cattle on grass, centipede grass, and crested wheatgrass hay; nutritive value and digestibility of grasses for sheep; blood phosphorus of range sheep; management and burning ranges; permanent marking and tattooing of sheep; methods for grinding feathers; relation of staple length to wool yield; shrinkage of wool in different breeds; ground soybean hay for swine; proteins in swine rations; deficiencies in the vitamin B complex, including pyridoxin and pantothenic acid for swine; the control of necrotic enteritis; rations for horses; the preservation of eggs by drying and oiling shells; the vitamin D requirement of turkey poults; effect of color of light on the well-being of chicks; relation of oils in the ration to egg production; and the relation of phosphorus, para-aminobenzoic acid, choline, and pantothenic acid to normal keel development.

[Livestock experiments by the Alaska Stations] (*Alaska Stas. Prog. Rpt.* 1938-41, pp. 7-8, 11-13, 17-21, figs. 2).—Results are briefly reported on projects

dealing with oat and pea silage as a substitute for dry cured hay for dairy cows, oat and pea pasture with and without grain for swine, pork curing and storage, raising dairy calves on a minimum of milk, and rations for wintering sheep.

[**Livestock feeding and grazing investigations by the Georgia Station**] (*Georgia Sta. Rpt. 1942*, pp. 45-49, 51, 57-62, 76, 102).—Brief results are reported on a comparison of peanut, soybean, sericea, kudzu, and lespedeza hays for fattening beef cattle; studies of corn and peanuts on the vine and peanut hay for fattening beef cattle; supplements to pasture in comparison with no supplements for beef heifers; wintering beef cattle with silage and peanut hay, with and without supplements, and corn and bagasse silages for wintering beef cattle; creep feeding beef calves on pasture; sweetpotatoes and vine storage in pit silos; the feeding value of potato meal for sheep; peanuts as a feed for hogs; temporary winter pastures for grazing cattle; grazing cattle on improved v. unimproved pastures; and the needs of potassium in swine feeding.

[**Studies in livestock production by the Kansas Station**] (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 35-39, 39-40, 44-45, 47-48).—Brief results are presented on the calcium requirements of swine, by C. E. Aubel, J. S. Hughes, and L. M. Roderick; soybean meal as a feed for lambs, by R. F. Cox; the mineral requirements of fattening cattle, continuing studies of fattening calves (E. S. R., 85, p. 94), and sorghum roughages and grains in the cattle-fattening ration, both by A. D. Weber and Hughes; dark cutters in beef and seasoning in pork sausage, by D. L. Mackintosh, J. L. Hall, and G. E. Vail; grass silage, modified rations, and artificial insemination for poultry and broiler production, and rations and breeding for turkey production, both by L. F. Payne, D. C. Warren, and A. E. Schumacher; egg yolk color and the role of pigments in poultry nutrition, by Payne, Schumacher, W. J. Peterson, and Hughes; and the nutritive value of dried eggs, shell treatment, and storage changes in poultry fat, by R. M. Conrad, Payne, Schumacher, and Vail.

[**Animal husbandry studies in Montana.**] (Partly coop. U. S. D. A.). (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 16-18, 46, 53, 57-60).—Results are reported by R. T. Clark which deal with feeding and performance tests with beef cattle, wool shrinkage, sheep breeding, range methods for sheep, and home-grown grains for feeding lambs; by D. Hansen on grain supplements for lambs; by R. M. Williams on feeding trials with crested wheatgrass for steers; and by F. S. Willson and J. R. Quesenberry on breeding and feeding trials with beef cattle.

[**Livestock investigations by the Oregon Station**] (*Oregon Sta. Bul. 401 (1941)*, pp. 19-20, 25-29, 33-34, figs. 4).—Results of projects on the following subjects are briefly reported: Keeping laying hens in batteries; value of green feeds for laying hens; comparison of pea vine silage, alfalfa hay, and wild hay for wintering beef cows; various rations for fattening baby beeves; wintering range ewes on grain hay and alfalfa hay, with and without molasses and wheat; palatability of pasture grasses and legumes for sheep; feeding value of cull dried pears for hogs; the effect of wheat and corn in the melting point of lard; proximity of water on Squaw Butte range for cattle; and grazing logged-off land with cattle and sheep.

[**Investigations in animal production by the Pennsylvania Station**] (*Pennsylvania Sta. Bul. 429 (1942)*, pp. 14-15, 26-29).—Brief results of studies by P. T. Ziegler, F. L. Bentley, T. B. Keith, M. A. McCarty, and R. C. Miller are given on the use of alfalfa-molasses silage for steers; soybean meal for pigs on rape pasture; soybean meal, dehydrated alfalfa meal, vacuum-dried liver, brewers' yeast, and carotene as valuable supplements to corn and tankage for pigs; and wheat bran, corn, and soybeans in the nutrition of lambs.

R. R. Murphy, P. Margolf, R. V. Boucher, H. Patrick, and W. T. S. Thorp report on plant protein feeds for poultry rations, lights in turkey production, riboflavin and turkey egg hatchability, separate incubators for hatching turkey poults, and range v. cut green feeds for turkeys.

**The utilization of urea by ruminants as influenced by the presence of starch in the ration**, R. C. MILLS, A. N. BOOTH, G. BOHSTEDT, and E. B. HART. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 925-929, fig. 1).—Continuing study of factors influencing the utilization of urea by ruminants (E. S. R., 86, p. 375), it was found that when urea was fed to a heifer with timothy hay, hydrolysis to ammonia was delayed in the rumen and the protein level was slightly lower than on timothy hay alone. Microbiological activity was great when starch was fed in addition to timothy hay and urea. It was completely hydrolyzed in 1 hr., and the ammonia disappeared with a concurrent rise in protein in the rumen contents. With the addition of casein to the hay, starch, and urea ration, the utilization of urea was markedly reduced. The study was conducted with a Holstein heifer from which rumen contents were removed through a fistula after being fed the different types of rations.

**Digestibility trials on green fodders**, E. HARRISON (*Trop. Agr. [Trinidad]*, 19 (1942), No. 8, pp. 147-150).—Analysis of 96 individual digestion trials with 15 fodders and four cattle each showed that consumption in the Tropics was considerably less than in temperate climates. Wilting was a suggestion to increase the dry matter and as a possible means of preservation. Consumption was increased to about the same as found under normal temperate conditions by the use of wilted elephant grass and para grass. Difficulties of silage making under wet tropical conditions and the use of molasses for preservation are noted.

**Wheat as a feed for livestock**, R. A. RASMUSSEN (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, pp. 1, 4).—A general discussion of the composition of wheat and its possibilities for rations of cattle, horses, sheep, and hogs.

**Commercial feeding stuffs, 1941-42**, E. R. TOBEY (*Maine Sta. Off. Insp.* 184 (1942), pp. 40).—The guaranteed and found analyses of 695 samples of feeds officially examined in the State are reported.

**Inspection of feeds**, E. J. DESZYCK, R. W. GILBERT, JR., and R. L. SWALLOW (*Rhode Island Sta. Feed Cir.*, June 1942, pp. 85).—The usual report on the guaranteed and found analyses of feeds officially examined in Rhode Island.

**Wildland grazing in northern Michigan**, D. L. WEAVER (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 83-93, figs. 14).—A general study of the use of wild land and cut-over land for grazing livestock in northern Michigan, based on a survey of existing conditions on second growth forests and land with few trees and shrubs.

**Use of pasture in a feeding program with steers**, G. A. BRANAMAN, H. A. FICK, and C. M. HARRISON (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 100-105).—Hereford cattle were divided into three lots for feeding from January 4 to August 28. One group was full-fed continuously in dry lot. The others were fed on alfalfa-brome pasture from May 15. Part of them had access to shelled corn in the self-feeder. The dry lot group made most rapid gains, and the least gains were made by those continuously fed on pasture alone. Because of the minimum labor requirements, the pasture produced as large net returns as most cultivated crops. Pasture when available is recommended for steer feeding.

**Wintering steers on crested wheatgrass**, R. M. WILLIAMS, R. T. CLARK, and A. R. PATTON. (Coop. U. S. D. A.). (*Montana Sta. Bul.* 407 (1942), pp. 18, figs. 6).—Long yearling steers practically maintained weight when wintered on mature crested wheatgrass pasture with 1 lb. cottonseed-molasses-beet pulp pellets per head daily. When the supplement was increased to 3 lb., gains of

0.34 lb. per head daily were made. In another wintering trial Fairway crested wheatgrass hay cut before the bloom stage, fed with 3 lb. of pellets per day, produced gains of about 1.5 lb. per head daily. Similar groups fed 0.9 lb. of soybean meal with Standard crested wheatgrass hay made gains of 1.3 lb. These conclusions were among those derived from three trials in which steers and calves were wintered for 140, 120, and 112 days, respectively.

**Relationship of rate of growth in lambs to body measurements and carcass value**, C. L. COLE (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 120-121).—Study of the relation of body measurements to average daily gains in 32 lambs at approximately 85 lb. live weight showed that average width of the individual had the highest relation to rate of gain. However, the most rapid gaining lambs were not necessarily those that graded highest when slaughtered. The thickness of fat over the eye muscle was the most important factor in slaughter grade but had little influence on the rate of gain.

**Studies on Merino wool production: The standard of production of a group of plainbodied stud ewes**, V. BOSMAN (*Farming in So. Africa*, 17 (1942), No. 191, pp. 88-98, figs. 4).—Good standards of production of total wool, length, and fleece density were exhibited by 50 Merino ewes of the plain bodied type without skin folds. Illustrations of the ewes and details of the number of fibers and fleece weights for each are given.

**Protein-mineral-vitamin supplements to barley in market hog rations**, E. W. CRAMPTON (*Sci. Agr.*, 21 (1941), No. 10, pp. 613-623).—Groups of 48 January- and 48 May-born pigs of the two sexes were divided for individual feeding and variance studies. Comparisons were also made of supplements to barley rations supplying high and low protein compositions from tankage, fish meal, brewers' yeast, and milk powder from weaning to 70 lb. in weight, from 70 to 110 lb., and 110 lb. to market weight. There seemed no advantage for increasing the crude protein level of the rations above 17 percent when linseed meal and tankage supplied the basis. The early advantages from protein levels above 17 percent were usually lost in the late growth period. The inclusion of fish meal in the protein supplement was recommended unless the cost was prohibitive. The sexes differed significantly in carcass quality and growth response.

**Ground alfalfa for brood sows**, V. A. FREEMAN (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 148-150).—Continuing studies with sows and gilts (E. S. R., 80, p. 527), comparisons were made of loose alfalfa hay self-fed, with corn hand-fed, and one part of ground alfalfa hay to two parts of ground corn hand-fed. The studies were conducted with about 50 sows and 50 gilts on each ration. During the 112 days after breeding there was no material difference in the farrowing or weaning data between the lots on the whole and ground alfalfa hay. The grain fed to both lots was approximately equal.

**Feeding sugar-beet molasses to hogs** (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, p. 8).—Young pigs were safely fed as much as 40 percent of the ration of sugar beet molasses with 5 percent of hay, or the equivalent of fresh green alfalfa or dried brewers' yeast.

**Swine raising in Arizona**, E. B. STANLEY, C. L. BELL, and J. T. RIGDEN (*Arizona Sta. Bul.* 185 (1942), pp. 27, figs. 6).—General directions for feeding and management of swine with diagrams of recommended types of equipment.

**Nicotinic acid deficiency studies in dogs**, A. E. SCHAEFER, J. M. MCKIBBIN, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 144 (1942), No. 3, pp. 679-685, figs. 2).—Continuing studies of the effects of vitamin B components on the dog (E. S. R., 88, p. 87), the single dose requirement of nicotinic acid was calculated as 200 $\gamma$ -225 $\gamma$  per kilogram of body weight per day for adult dogs and 250 $\gamma$ -365 $\gamma$  for growing puppies. The response of the nicotinic acid deficient dog

to nicotinic acid, nicotinamide, dried liver, and liver extract powder feeding was inhibited by sulfapyridine, but the inhibition was overcome by fresh liver. These conclusions were derived from studies of the benefits of daily supplements of nicotinic acid for deficient dogs on the casein-sucrose diet supplemented with components of the vitamin B complex (except nicotinic acid).

**The analysis of covariance by the method of individual comparisons,** J. B. O'NEIL (*Sci. Agr.*, 22 (1942), No. 11, pp. 721-724).—The methods of carrying out variance and covariance analysis for data on gains in weight and increases in the fat percentage in poultry on two feeds and two supplements at three temperatures previously noted (E. S. R., 88, p. 88) are presented in detail.

**Lactobacillus casei** *ε* **factor in the nutrition of the chick,** R. C. MILLS, G. M. BRIGGS, JR., C. A. ELVEHJEM, and E. B. HART. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 186-189, figs. 2).—Further study of the factor needed for growth of bacteria and the chick (E. S. R., 86, p. 667) showed that additions of 2 percent of liver extract to a basal ration on which chicks grew poorly supplied all other essential factors and growth was stimulated, hemoglobin formation at 4 weeks was normal, and feathering at 5 weeks was good. A norit eluate of the liver proved as effective. Additions of glycine and arginine at adequate levels to the basal ration did not improve feathering or growth.

**Lysine requirement of the chick,** H. J. ALMQUIST and E. MECCHI. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 174-176).—In one experiment conducted by methods previously noted (E. S. R., 86, p. 666), the additions of 0.8 percent lysine to the basal diet produced gains in five chicks in 7 days only slightly less than were made by positive controls which received casein. In another experiment 0.85 percent supplements of lysine gave practically as good growth as 0.95 percent rations. The third experiment also indicated that the lysine requirement for optimum growth was approximately 0.9 percent of the diet. Edestin, glycine, and *DL*-methionine did not replace the need for lysine.

**Nicotinic acid in chick nutrition,** G. M. BRIGGS, JR., R. C. MILLS, C. A. ELVEHJEM, and E. B. HART. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 59-61).—Continuing studies of deficiencies in chick diets as noted by Waisman and Elvehjem (E. S. R., 84, p. 803), additions of 0-10 mg. of nicotinic acid per 100 gm. of ration increased the growth of chicks up to 3 weeks of age with additions up to 1.5 mg. per 100 gm. of ration. Since the basal ration contained 0.3 mg. of nicotinic acid per 100 gm., it was estimated that the minimum level of the vitamin was 1.8 mg. for optimum growth. The study was conducted with 8 lots of 6-18 chicks each.

**Prevention of perosis by biotin,** T. H. JUKES and F. H. BIRD. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 231-232).—The symptoms of perosis developing in chicks on rations containing about 30 cc. of raw egg white, as noted by McElroy and Jukes (E. S. R., 85, p. 802), did not develop if the egg white was omitted or if cooked egg white replaced the raw product. The symptoms of perosis were also prevented by injecting approximately 3  $\mu$ g. of biotin daily, or in another experiment by injecting the chicks with a total of 13  $\mu$ g. of biotin in seven injections. A dose of 0.34  $\mu$ g. of biotin per day did not prevent dermatitis, but it induced superior growth and feathering.

**Changes in the National Poultry Improvement Plan** (U. S. Dept. Agr., Misc. Pub. 300, Sup. (1942), pp. 5).—A supplement to the publication previously noted (E. S. R., 79, p. 91) with corrections to date in the National Poultry Improvement Plan.

**Hatching ability of poultry.**—III, The market quality criterion—mobility of yolk and hatchability, E. W. HENDERSON (*Michigan Sta. Quart. Bul.*, 25

(1942), No. 2, pp. 151-156, fig. 1).—Continuing this series (E. S. R., 88, p. 237), a relation of hatching power to yolk movement in 2,413 eggs was shown. These results indicated that 73 percent of the eggs hatched from those showing the greatest yolk movement on candling, as compared with 62 percent of the eggs hatched from those which showed the poorest yolk movement. A regression line of percentage hatched on yolk movement is presented.

**Broiler production**, H. O. WEST (*Mississippi Sta. Bul.* 370 (1942), pp. 90, figs. 25).—This is a revision of Bulletin 335 (E. S. R., 82, p. 527), giving, in addition to compiled data, a summary of feed costs and returns from the production of nearly 30,000 broilers on nearly 25 farms in the Smith, Rankin, and Scott County areas of Mississippi. Surveys are also included of broiler production in other States for comparison and the results of feeding experiments elsewhere.

**The structure and quality of eggs**, A. M. GERICKE (*Farming in So. Africa*, 17 (1942), No. 191, pp. 117-131, figs. 4).—The interior areas of the membranes, shell, and albumen of the egg are briefly discussed, with special reference to time in the egg cycle.

**Feeding and confinement rearing experiment with turkeys during 1941**, F. N. BARRETT, C. G. CARD, and A. BERRIDGE (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 138-148).—Continuing studies of turkey production (E. S. R., 86, p. 668), the amount of grain consumed was increased when corn and oats were fed free choice, as contrasted with corn alone with mash containing 28.6, 32.2, and 22.1 percent protein. Whole oats proved a desirable feed, but corn was consumed heavily as maximum growth was attained and there was greater fattening. The study was conducted with 10 lots consisting of about 25 Small-type Bronze, Bronze, Bourbon Red, Beltsville Small White, and crossbred turkeys each, fed for 26 weeks. The smaller types consumed slightly more feed per unit of gain. The practicability of confinement rearing of turkeys was demonstrated.

**Alfalfa meal in turkey rations** (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, p. 8).—As much as 25 percent alfalfa meal in the mash produced as good or better finish on turkeys as 5-10 percent. There was no apparent advantage for the use of skim milk or wet mash.

## DAIRY FARMING—DAIRYING

**Report of the Chief of the Bureau of Dairy Industry, 1942**, O. E. REED (*U. S. Dept. Agr., Bur. Dairy Indus. Rpt.*, 1942, pp. 26).—Results are briefly reported of work by R. R. Graves of progress made on investigations at the Beltsville Research Center and field stations on the development of improved strains of Holstein-Friesian and Jersey cattle, production of bulls for artificial breeding rings and bull associations, relation of development of mammary gland of calf to milk production in later life, effect of suspension of milking on production, pasturing cattle and feeding tests, silage from alfalfa, and soybeans with and without preservatives for milk production.

C. A. Cary reported briefly for the division of nutrition and physiology on the composition and chemical reaction of milk proteins, further studies of the unidentified nutritional factors in milk and other substances (E. S. R., 88, p. 519), gonad-stimulating plant materials, the vitamin A and carotene values of corn silages, alfalfa, and timothy hays, effect of rations low in vitamin A on reproductive functions and dilution and quality of semen, limiting factors for milk production and growth in grain and timothy hay, and grain and corn silage rations.

Brief results are presented of work by L. A. Rogers on studies of types of bacteria developing in Swiss and Cheddar cheese during manufacture and the cause of low-grade cheese production in the field, sweetness of ice cream, temperature of heating and sterilization of evaporated milk and bacteria present, development of lactic-acid lacquers, and oxidative deterioration of fats in dairy products.

Brief results are reported by E. Kelly on market milk investigations concerned with tests of filter pads and decreases in the tin content of solder for milk cans, substitutes for agar in milk counting on solid media, effect of homogenization on curd tension, digestibility, keeping quality, and flavor, development of oxidized flavor by milk in copper-containing cans when cows received silage as contrasted with dry feed, relation of oxidase-producing bacteria to development of oxidized flavors in milk, and practices of producers and distributors in cooling, bottle washing, refrigeration, and bottle filling.

[Experiments in feeding dairy cattle by the Georgia Station] (*Georgia Sta. Rpt. 1942*, pp. 41-44, figs. 2).—Brief results are presented on the use of home-grown roughages in the dairy ration, sweetpotato meal and peanuts on the vine as a milk-producing feed for dairy cattle, and the growth and development of dairy heifers on summer pasture when receiving supplementary concentrates.

[Investigations of dairy production by the Kansas Station] (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 40-42).—Brief results are presented on studies showing the deficiencies of sorghum crops as feed for dairy cows, by H. E. Bechtel, F. W. Atkeson, and J. S. Hughes; raising calves on Coyner nipple pail, and production of vealer calves, by A. O. Shaw and Atkeson; effects of evaporation, breeds, etc., on the composition of milk, by W. J. Caulfield and C. H. Whitnash; and fly control, nitrogen, and silage studies affecting dairy production, by Atkeson, Bechtel, Shaw, G. H. Beck, W. M. McLeod, Hughes, and R. C. Smith.

[Dairy research in Montana] (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 25-26).—Work is reported by J. A. Nelson on profitable levels for grain feeding, dry meal v. skim milk powder for dairy calves, and abnormal flavors in milk.

[Production by dairy cattle and manufacture of dairy products]. (Partly coop. U. S. D. A.). (*Pennsylvania Sta. Bul. 429 (1942)*, pp. 6-8, 9-10, figs. 2).—Results are briefly presented of studies by A. A. Borland, A. L. Beam, S. I. Bechtel, R. W. Stone, J. E. Nicholas, T. G. Anderson, C. D. Dahle, D. V. Josephson, F. J. Doan, and O. M. Russell on milk produced by cattle fed from 70 to 120 percent of the Haecker standard for milk production; inheritance of milk-producing capacity in institutional herds; the use of corn meal, wilting, salt, mixture with green wheat, mixture with dry sorghum, and mixture with stored beets, and all combinations thereof for preservation of grass silage; well water not ideal as a milk-cooling medium; reducing length of cheese-curing period by new starter; loss of vitamin C in making evaporated milk; dried whole and skim milk and incubation for controlling the oxidized flavor in milk.

Grazing habits of dairy cattle, F. W. ATKESON, A. O. SHAW, and H. W. CAVE. (Kans. State Col.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 779-784, fig. 1).—Grazing 2 cows on each of six different pastures of about 4 acres each showed that the cows spent slightly less than half their time in grazing on good pasture during the day time. On fair and poor pasture 55 and 62 percent, respectively, of the time was spent in grazing. There was no relation of frequency of drinking to the type of pasture available. In a more detailed study of 56 dry cows and heifers continuously on 30 acres of rye pasture without supplemental feeding, the 24 hr. were spent as an average of 7 hr. in grazing, 4 hr. standing or walking, and 13 hr. lying down. The animals were lying down 35 percent of the day and 80

percent of the night. There were four grazing periods during the day and two at night.

**Studies on ketosis in dairy cattle.**—I-III, C. B. KNOTT, J. C. SHAW, and G. C. WHITE. ([Conn.] Storrs Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 10, pp. 837-867, figs. 17).—Three studies in this series are reported.

I. *Effect of stall and pasture feeding upon the concentration of blood and urinary acetone bodies of dairy cattle* (pp. 837-849).—Total acetone in the blood and urine of 3 cows was markedly increased 2-4 hr. following the feeding of grass silage. In several determinations at monthly intervals over 12 mo. with 11 mature cows and 1 mature bull, those receiving grass silage showed a marked increase in the blood and urine acetone bodies. A marked decrease was noted 2-3 hr. later with the return to normal after 9 hr. Through the winter months with heavy silage rations the blood and urine acetone increased, but decreased during the pasture season. Heifers 16-20 mo. of age kept on pasture did not show the increase associated with silage feeding. Variations in acetone bodies were associated with the  $\beta$ -hydroxybutyric acid in the blood and urine. The increase in the acetone bodies during the stall feeding period was more closely associated with grass silage feeding than with any other single factor. Low values were noted in the winter months with hay. The blood acetone of helpers was lower on mixed grass hay than on pasture.

II. *Blood and urinary acetone bodies of dairy cattle in relation to parturition, lactation, gestation, and breed* (pp. 851-860).—Observation of the acetone bodies of 11 lactating cows at monthly intervals over a 15-mo. period showed much variation, but there was a gradual increase in the blood and urine for 90 days after parturition followed by a gradual decline. In 5 cows on which daily observations were made, there was a marked decrease in the urinary acetone bodies during 4 days after parturition, but the decline was not statistically significant at the time when the incidence of ketosis is greatest. Factors other than pregnancy seemed to affect the day-to-day variations in 10 cows at various stages of gestation. No increase in the blood and urinary  $\beta$ -hydroxybutyric acid followed the cessation of milking. Breed differences seemed related to differences in silage consumption. There appeared to be no correlation between milk and blood acetone bodies within the normal range. Highly significant correlations were noted between the blood and urinary concentration of total acetone bodies, acetone and acetoacetic acid, and  $\beta$ -hydroxybutyric acid.

III. *Blood and urinary acetone bodies as related to age* (pp. 861-867).—Study of the blood and urinary acetone bodies of calves at birth and their dams, helpers from birth to 10 mo. of age, and heifers from 9 to 26 mo. of age showed no correlation between the calves and their dams. The acetone bodies were extremely low during the first 7 days following birth, and this condition lasted for the first 2 mo., followed by progressive increase due to  $\beta$ -hydroxybutyric acid. It was also noted that helpers receiving pasture grass alone showed a higher concentration of blood acetone bodies than when receiving hay and grain.

**The fat metabolism of the mammary gland of the normal cow and of the cow in ketosis**, J. C. SHAW, R. C. POWELL, JR., and C. B. KNOTT. ([Conn.] Storrs Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 909-921).—In continuing the study of the effect of ketosis and the administration of large quantities of glucose in ketosis on the type of fatty acids in the milk (E. S. R., 84, p. 663), the short chain fatty acids of milk fat increased significantly within 36-48 hr. after administration of 6 lb. of glucose directly into the rumen. However, in severe ketosis the short chain fatty acids are lowered but not as much as in short periods of fasting. On the evidence obtained it appears that  $\beta$ -hydroxybutyric acid is one of the chief sources of energy for the active mammary gland. Removal of

fat and glucose from the blood in its passage through the mammary gland accounted for 92.8 and 105.5 percent, respectively, of the fat and lactose secreted in the milk. The studies were conducted by detailed analyses of the blood and milk fat produced by four cows in five experiments.

**Rôle of inositol and *p*-aminobenzoic acid in normal lactation**, D. R. CLIMENKO and E. W. MCCHESENEY (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 157-159, fig. 1).—The need of inositol for normal lactation in the rat is emphasized. Five groups of 12 individuals each received a deficient diet supplemented with vitamin B complex, with and without *p*-aminobenzoic acid and inositol singly and in combination. The milk secretion was indicated by the increase in weight of the young. Inositol maintained lactation only slightly less than a control diet and *p*-aminobenzoic acid additions did not increase milk production, but mortality of the young was slightly decreased.

**The effect of stilbestrol and anterior pituitary extract upon lactation in goats**, A. A. LEWIS and C. W. TURNER. (Univ. Mo.). (*Jour. Dairy Sci.*, 25 (1942), No. 10, pp. 895-908, fig. 1).—In continuation of previous investigations (E. S. R., 86, p. 377), copious and prolonged lactation was induced in virgin and dry goats by the subcutaneous, oral, or percutaneous administration of diethylstilbestrol, or by implantation of pellets of diethylstilbestrol dipropionate. The daily effective doses required by the different methods of administration were oral 5 mg., inunction 4 mg., and subcutaneous 0.25 mg. Anterior pituitary extract augmented the production caused by diethylstilbestrol, presumably from the action on the anterior pituitary gland, causing increased production of lactogen or by initiating lactation in stilbestrol-treated goats. Stopping daily treatments sometimes improved production, but restarting them had little effect. The volume of production was not benefited by hormone treatment of parturient goats. Treatment during the last half of pregnancy was not deleterious to normal parturition and did not have any adverse effect on the health of goats when continued over long periods. Two does were bred out of season after termination of the hormone treatment.

**The conversion of surplus wheat into much needed milk**, G. Q. BATEMAN (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, pp. 1, 11, fig. 1).—Records of the milk production and feed consumption of cows in the experiment station herd showed that as production increased the total digestible nutrients required to produce a pound of butterfat decreased. Chopped wheat was fed at a profit as the single grain with alfalfa hay, but wheat was fed to greater advantage to dairy cows when it made up only a part of the grain mixture. Returns were estimated on different prices of butterfat.

**Shark liver oil and the vitamin A potency of milk**, L. L. RUSOFF, H. E. SKIPPER, and P. T. D. ARNOLD. (Fla. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 807-813).—The administration of 2.5, 5, and 10 lb., respectively, of shark-liver oil per ton of feed, or 4-6 oz. of this substance per cow, did not raise the vitamin A in the milk above a threshold of about 1,900 I. U. per quart. This amount occurred with the smaller supplement of shark-liver oil. Cows were furnished with these feeds in three groups of two each with four cows kept for controls in two pasture and one dry-lot periods. There was a significant decrease in the vitamin A potency of the milk when pasture was limited. With the shark-liver oil supplement there was a decrease in the fat percentage of the milk, but the vitamin C content was not significantly affected.

**The use of laboratory pasteurization in solving milk problems**, E. B. BOYCE, H. C. LYTGOE, E. K. RUGGLES, and R. LANE (*Jour. Milk Technol.*, 5 (1942), No. 3, pp. 146-151, figs. 2).—Bacteriological counts of milk samples before

and after pasteurization were indicative of the source of contamination. The problem of improving the bacteriological quality of the milk sold in Massachusetts was largely a matter of improving the quality of the farm milk supply, but regular milk inspection must be maintained. The study was based on standard plate counts before and after laboratory pasteurization of milk samples regularly collected.

**Prevention of development of hydrolytic rancidity in milk**, N. P. TARASSUK and J. L. HENDERSON. (Univ. Calif.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 801-806, figs. 3).—Mixtures of 80 percent normal milk with 20 percent milk having a high lipolytic activity with the early development of rancidity prevent the occurrence of the rancid flavor. Surface tension and organoleptic tests confirmed each other in supporting these findings. More or less variation in the surface tension occurred with more than 20 percent of the lipolytic milk.

**A comparative study of the Frost little plate and standard plate methods for the bacteriological examination of milk, cream, and ice cream**, C. S. BRYAN, M. V. SCHEID, M. D. NEUHAUSER, B. L. GILBERT, and G. J. TURNEY. (Mich. Expt. Sta. et al.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 827-835).—Study of the bacterial counts of 445 samples of milk and cream and 165 samples of ice cream showed that counts comparable to standard plate counts were obtained by incubating Frost little plate samples (E. S. R., 45, p. 175) for 4 hr. at 37° C. in a moist chamber when the counts were made on milk and cream and 8 hr. for counts on ice cream. Dilution of 1-10 or 1-100 are suggested for chocolate, fruit, and nut flavoring in order to differentiate the particles from living bacteria.

**Composition and thiamin and riboflavin content of defatted milk solids**, C. M. O'MALLEY and E. J. BALDI (*Jour. Milk Technol.*, 5 (1942), No. 3, pp. 138-140).—No relationship was found between the thiamin and riboflavin contents of defatted milk solids in 32 samples from 13 of the major milk-producing States representing widely different geographical districts. The samples were analyzed for moisture, fat, protein, lactose, ash, calcium, phosphorus, thiamin, and riboflavin.

**Influence of pH, type of fat, and pancreatic extract upon lipolysis in homogenized milk**, I. A. GOULD. (Mich. State Col.). (*Jour. Dairy Sci.*, 25 (1942), No. 10, pp. 869-876, fig. 1).—In a continuation of previous studies (E. S. R., 86, p. 378) the extent of lipolysis was ascertained in series of homogenized butter oil and whey adjusted to pH 4, 5, 6.5, 8, 8.5, 9, 9.5, and 10. There was no lipolysis at pH 4 and 5, and there was great retardation at pH 10. Other trials in which the samples were first acidified and then adjusted to pH 8-8.5 showed that acid treatment adversely and permanently affected the lipolytic activity of whey and it failed to respond to subsequent alkaline treatment. Homogenization of cottonseed oil, castor oil, coconut oil, and other oils and fats with raw and pasteurized skim milk showed milk to contain a nonspecific fat-splitting enzyme capable of producing lipolysis on a wide variety of fats. Homogenization greatly enhanced lipolysis produced by pancreatic extract, whether before or after the addition of the enzyme.

**Orthophosphoric acid as a cheese solvent**, A. W. TURNER, B. ROGERS, and V. CONQUEST (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 777-778).—The extraneous matter in a 50-gm. sample may be ascertained by dissolving the cheese in 500 cc. of hot orthophosphoric acid and filtering.

**The use of enzyme-converted corn sirup in the manufacture of bulk sweetened condensed milk**, P. H. TRACY and G. EDMAN. (Univ. Ill.). (*Jour. Dairy Sci.*, 25 (1942), No. 9, pp. 765-775, pl. 1).—In samples of sweetened condensed skim milk, corn sugar replacing 50-100 percent of the sucrose was

found to have normal keeping qualities but discoloration was greater. Best results from the standpoint of color and thickening were obtained when the milk and sirup were preheated separately at temperatures limited to 185° F. with storage at low temperatures. In commercial operations the storage temperature did not need to be lower than 60° unless the condensed milk was to be stored more than 3 mo. These results were derived from the study and color quality of samples prepared with 0-42 percent sucrose or corn sirup and preheated at 170°-200° with storage at 40°-90°.

**Bacteriological study of chocolate milk,** J. E. FULLER, W. S. MUELLER, and R. W. SWANSON. (Mass. State Col.). (*Jour. Dairy Sci.*, 25 (1942), No. 10, pp. 883-894).—This study of chocolate milk, the milk and three sirups, and three cocoa powders from which it was made, showed that cocoa powder contained some factor which inhibited the growth of bacteria ordinarily present in milk except *Streptococcus lactis*. Tannic acid produced a similar effect. Neither oxalic acid or theobromine alone has demonstrable effects on bacterial growths. The limitation of bacterial development was not apparent in chocolate milk made from one chocolate sirup. In the studies the chocolate milk was stored for varying periods up to 7 days. The bacterial counts in chocolate milk followed those changes found in raw milk. The growth-inhibiting factor was evidently lost in the manufacturing process.

**Frozen cream as a source of fat in ice cream,** M. V. SCHEID, P. S. LUCAS, and G. M. TROUT (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 125-132, figs. 2).—The use of frozen cream as the sole source of fat in ice cream retarded the whipping ability of the mix. There was no difference in the time required for a 90-percent overrun for frozen cream held 1, 3, or 6 mo. A 90-percent overrun was obtained more easily in ice cream when 10 percent sucrose was added before freezing the cream for storage. The delayed whipping with frozen cream was largely overcome by the use of 0.35 percent dried egg yolk. The flavor of ice cream from frozen cream was slightly improved by the addition of egg yolk, and a good flavor was maintained over a longer storage period, but there was no consistent influence of frozen cream on the body and texture of the ice cream. The use of frozen cream in the mix did not raise the bacterial count of the ice cream after storage for 6 mo.

**Meeting sugar shortages in preparing ice cream ripple syrups,** J. SHEVRING and P. H. TRACY. (Univ. Ill.). (*Ice Cream Rev.*, 26 (1942), No. 1, pp. 18-20).—Study of different ingredients showed that satisfactory wartime commercial ripple gelatin can be made by 20 percent fruit, 0.5 percent pectin, and 35 percent sweetening on a solids basis from invert sugar or sirup, corn sirup, honey, or sorghum molasses. These materials also proved satisfactory as replacements for all or part of the sucrose in chocolate ripple syrups.

**Substitutes for cocoanut oil in chocolate ice cream coatings,** J. J. SHEVRING and P. H. TRACY. (Univ. Ill.). (*Ice Cream Trade Jour.*, 38 (1942), No. 10, pp. 64, 110-112).—The results of tests to find domestic oils and fats that could be substituted for coconut oil in chocolate coatings showed that 8-15 percent of low-melting-point fats and 10-25 percent of high-melting-point fats could be employed. A satisfactory coating for emergency use was made with 10 percent cocoa, 40 powdered sugar, 35 hydrogenated soybean oil, and 15 percent unhydrogenated soybean oil.

**Stretching your supply of coating,** J. H. ERB. (Ohio State Univ.). (*Ice Cream Trade Jour.*, 38 (1942), No. 10, pp. 26-27, 77-78, fig. 1).—Various supplements to ice cream coating fats are suggested, including lecithin from soybeans as a go-between moisture and fats and confectioner's coating with added fat.

## VETERINARY MEDICINE

[Work in animal pathology and parasitology by the Bureau of Animal Industry] (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt., 1942, pp. 2-5, 18-46*).—A progress (E. S. R., 86, p. 676) report of work with Bang's disease; tuberculosis; bovine mastitis; the avian leucosis complex; eradication of scabies and of dourine; anthrax; inspection and quarantine of imported animals and products; infectious equine encephalomyelitis; periodic ophthalmia; swine erysipelas; infectious anemia; miscellaneous diseases; stock-poisoning plants; pullorum disease antigens; disinfectants; tuberculin and other diagnostic tests; anaplasmosis; liver abscesses in feed lot cattle; tick eradication; hog cholera and its control; Johne's disease; and parasites of horses, cattle, sheep, swine, and poultry and treatment for their removal.

[Work in animal pathology and parasitology by the Kansas Station] (*Kansas Sta. Bien. Rpt. 1941-42, pp. 57-61*).—The work of the biennium (E. S. R., 85, p. 104) reported upon by L. M. Roderick, R. P. Wagers, W. W. Thompson, J. H. Whitlock, C. H. Kitselman, H. Farley, V. D. Foltz, L. D. Bushnell, F. W. Atkeson, P. H. Vardiman, and J. E. Ackert relates to equine encephalomyelitis; hemoglobinuria in cattle; canine meningoencephalitis; lymphogenous leukemia; contagious abortion in cattle; anaplasmosis; diseases of feeder cattle; mastitis of dairy cows; poultry disease investigations, including effect of phenothiazine on hemoglobin in fowls, protozoan parasites, pullorum agglutination test, lymphomatosis, fowl paralysis, and trichomoniasis; parasitological investigations with the chicken tapeworm *Railletina cesticillus*; and the resistance of chickens to the nematode *Ascaridia galli*.

[Work in animal pathology by the Montana Station.] (Partly coop. U. S. D. A.). (*Montana Sta. [Bien.] Rpt. 1941-42, pp. 35-37*).—The work of the biennium (E. S. R., 84, p. 668) reported on by H. Marsh relates to the use of iodized salt for the prevention of goiter in newborn pigs, lambs, calves, and colts; dysentery or scours in young lambs; arthritis in lambs; foot rot in sheep; vaccination against "black disease" in sheep; control of Bang's disease in range cattle; and coccidiosis in cattle and feed lot lambs.

[Work in animal pathology and parasitology by the Oregon Station] (*Oregon Sta. Bul. 401 (1941), pp. 17, 22, 23, 30-32, figs. 2*).—The work of the biennium 1939-40 (E. S. R., 82, p. 387) reported upon relates to rumen gases and bloat in ruminants; coccidiosis and infectious laryngotracheitis in chickens; swine erysipelas, *Hexamita* sp., and infectious sinusitis in turkeys; paratyphoid in turkey poults and chicks; stiff lamb disease; pulpy kidney disease, black disease, and progressive pneumonia or "lunger" disease of lambs; diseases of milk goats; fern poisoning in cattle; liver fluke in cattle, sheep, and goats; and lungworms.

[Work in animal pathology by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 429 (1942), pp. 8, 26*).—Work on the cause of calf pneumonia and the effectiveness of sulfapyridine in the treatment of calf pneumonia and sulfaguanidine in the treatment of scours is noted by W. T. S. Thorp. D. R. Marble reports on selection and culling as a control measure for fowl paralysis.

A study of the phenomenon of erythrocyte sedimentation.—I, A critical survey of literature. II, The establishment of a reliable measurement of the phenomenon—its reproducibility and limitations, R. E. NICHOLS (*Jour. Lab. and Clin. Med.*, 27 (1942), Nos. 10, pp. 1317-1327; 11, pp. 1410-1422, figs. 6).

The chorioallantoic membrane of chick embryos and its response to inoculation with some mycobacteria, M. MOORE (*Amer. Jour. Pathol.*, 18 (1942),

No. 5, pp. 827-847, figs. 25).—Strains of human, bovine, avian, fish, and snake tubercle bacilli and of rat leprosy bacilli were inoculated in the chorioallantoic membrane of the developing chick, and the histopathogenesis of the lesion which they produced was studied and differentiated. It is concluded that the type of reaction and the degree of response of the membrane to the inoculum serve to determine virulence in a relatively short time.

**"Sulfasuxidine" succinylsulfathiazole in veterinary practice**, A. H. BRYAN (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 22-26).—This contribution includes canine and feline case reports which, from a clinical standpoint, indicate that succinylsulfathiazole as compared with other sulfonamides is non-toxic even in large dosages and may be given to small pups with safety. It may retard the progress of catarrhal, respiratory, and nervous forms of distemper, but is not as effective as sulfadiazine or sulfathiazole in bringing about a prompt cure of the disease. It is useful in bacillary dysenteries and paradysenteries of the dog and cat and is indicated in food poisoning cases. It is particularly effective in controlling dysenteries of pups and thereby reduces the mortality. Succinylsulfathiazole is not absorbed to any extent by the blood stream. It acts bacteriostatically on the intestinal micro-organisms, particularly on the coliform group and possibly on the spore-forming anaerobes. Marked decreases were noted in the number of coliform intestinal organisms following the administration of medium or maximum doses. The drug appears to be effective against certain pathogens of the intestinal flora. Because of the lack of absorption into the blood stream, this drug may be considered the least toxic of all the sulfonamide drugs and may, therefore, be administered in double dosages in severe enteric cases.

**The action of sulfanilamide compounds on the lethal factor of bacterial toxins**, S. H. HUTNER and P. A. ZALL (*Science*, 96 (1942), No. 2503, pp. 563-564).—Sulfanilamide compounds were found to protect mice against multiple lethal doses of purified *Salmonella* endotoxin. This protective action is inhibited by *p*-aminobenzoic acid.

**The sulfonamids—therapy in practice**, J. A. S. MILLAR (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 51-56).

**Sulfaguanidine in veterinary medicine** (*Vet. Bul. Lederle*, 11 (1942), No. 2, pp. 27-31, fig. 1).—A review of the literature on sulfaguanidine employed in the treatment of white scours of calves, swine enteritis, enteric infections in dogs and cats, and coccidiosis in poultry and lambs.

**Wound healing**, A. D. HOLMES (*New England Jour. Med.*, 227 (1942), No. 24, pp. 909-921).—A review of the literature, with a list of 146 references.

**Brucellosis: Studies emphasizing strain variation in serologic testing**, F. E. ANGLE, W. H. ALGIE, and D. MORGAN (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 10, pp. 1259-1263, figs. 3).—A series of 34 patients diagnosed as having chronic undulant fever were examined, agglutination and opsonocytophagic tests being applied. Marked variation in both agglutinin titers and opsonocytophagic indices were found, which indicated the necessity for standardization of *Brucella* polyvalent antigens for agglutination tests. Testing with 5 to 10 smooth strains for cyptophagic activity is necessary to obtain reliable results.

**A staining procedure for use in the *Brucella* opsonocytophagic test**, N. B. McCULLOUGH and L. A. DICK (*Stain Technol.*, 17 (1942), No. 4, pp. 153-155).—Description is given of a staining procedure which is recommended for use in the *Brucella* opsonocytophagic test in order to avoid confusing results obtained with stains of the Hasting or Wright type.

**Intranasal and intraperitoneal infection of the mouse with *Coccidioides immitis***, M. TAGER and A. A. LIEBOW (*Yale Jour. Biol. and Med.*, 15 (1942), No. 1,

pp. 41-59, figs. 17).—The comparative effects of intranasal and intraperitoneal infection of the mouse with the *C. immitis* fungus are presented.

**Foot and mouth disease**, A. E. CAMERON (*Canada Dept. Agr. Pub.* [737] (1942), pp. 14, figs. 6).

**Johne's disease in farm animals**, D. F. EVELETH and R. GIFFORD. (Ark. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 27-34, fig. 1).—In continuation of earlier work (E. S. R., 88, pp. 100, 243) record is made of the finding of swine, sheep, goats, horses, mules, and cattle to be sensitive to the intradermal Johnin test. Clinical cases of Johne's disease were observed in cattle and sheep but not in the other species. It is considered probable that Johne's disease may act as a predisposing factor in the production of other disease conditions in cattle and sheep.

**Ornithosis (psittacosis) in pigeons and its relation to human pneumonitis**, K. F. MEYER, B. EDDIE, and H. Y. YANAMURA. (Univ. Calif.) (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 609-615).

**Pathological changes in *Listerella* infection, particularly of the eye**, L. A. JULIANELLE and E. MOORE (*Amer. Jour. Pathol.*, 18 (1942), No. 5, pp. 813-825, figs. 15).—Studies of the histopathological changes in the ophthalmic response of several species of animals to infection with organisms of the genus *Listeria* are reported.

**A practical suggestion for the serological type determination of *Salmonella* organisms**, S. BORNSTEIN (*Jour. Bact.*, 44 (1942), No. 6, pp. 719-720).

**The pathogenicity of *Streptococcus agalactiae* for mice and treatment with sulfanilamide and a derivative**, M. M. KAPLAN, G. W. RAIZISS, and J. C. MOETSCH (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 392-394).—*S. agalactiae*, which is ordinarily nonpathogenic in mice, has shown a marked pathogenicity when passed through a series of mice. The therapeutic action of sulfanilamide and sodium formaldehyde sulfoxylate-sulfanilamide seems to be inhibited in mice infected with *S. agalactiae* in neopeptone blood broth medium. Sulfanilamide and sodium formaldehyde sulfoxylate-sulfanilamide exert a specific therapeutic action in mice infected with *S. agalactiae* in a saline suspension.

**Diseases of feeder cattle in Kansas**, H. FARLEY (*Kansas Sta. Cir.* 214 (1942), pp. 14).—A practical account of diseases of feeder cattle in the State, including (1) the three infectious diseases shipping fever, keratitis or pinkeye, and coccidiosis or red dysentery of cattle, and (2) several general diseases, namely, cornstalk disease, prussic acid poisoning, mineral deficiency, silage poisoning, malnutrition, photosensitization, ergot poisoning, and bloating.

**A baffling disease of Mid-West cattle**, A. BRITE (*Vet. Med.*, 37 (1942), No. 9, pp. 386-387, figs. 2).—Account is given of a hemoglobinuria which occurs in the Midwest and is entirely different from post parturient hemoglobinuria and the hemoglobinuria produced by *Clostridium hemolyticum bovis*. The disease affects cattle of all ages and breeds. Post-mortem lesions resemble those of other hemoglobinurias. The main differences are absence of the infarct in the liver as described in *C. hemolyticum bovis* infection and the lack of the advanced degeneration of the parenchymatous organs as observed in postpartum hemoglobinuria. The cause is unknown, but plant poisoning is suspected despite the fact that some cases have occurred in bucket-fed nursing calves and feed lot cattle. Trypanosomiasis have not been ruled out.

**The response of "ceased" reactors in Bang's disease to reexposure**, B. A. BEACH, M. R. IRWIN, and L. C. FERGUSON. (Wis. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 11, pp. 523-532).—In the investigation reported only 1 of 16 infected cows which became ceased reactors, the agglutination titers of the serums having become no higher than those of noninfected ani-

mals, aborted its fetus when reexposed to *Brucella abortus*. *B. abortus* was isolated at parturition from only 1 other ceased reactor following their reexposure. In general, the agglutination titers of the serums of the different ceased reactors were either lower or approximately the same during the second as during the first infection. These results, combined with others obtained elsewhere support the general belief that an active immunity to *B. abortus* results from such infection with virulent organisms and indicate that immunity is of a relatively long duration.

**The diagnosis of actinomycosis and actinobacillosis**, M. S. SHAHAN and C. L. DAVIS. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 321-328, 329, figs. 6).—In studies of 78 animals having these lesions 68 cases were found due to actinobacillosis, and cultures of both infections were obtained from 1 animal. The cases showing lymph node involvement, alone or in combination with other lesions, were all actinobacillosis. Of the 11 animals showing actinomycosis, 6 were bone cases and 5 had lesions of various organs not associated with bone or lymph node involvement. It is pointed out that while the two diseases are commonly considered in the same category from a clinical point of view, technically they are distinct entities. The causative organisms of the two diseases are capable of producing rosettes, but they differ materially in their cultural and morphological characteristics. *Actinomyces bovis* is anaerobic or microaerophilic and gram-positive, while *Actinobacillus lignieresii* is aerobic and gram-negative. Cultural methods, when possible, are the most desirable to differentiate these diseases from other suppurative processes. The authors' studies indicate, however, that a practical differential diagnosis of these two diseases can be made satisfactorily in many, if not most, instances without resorting to cultures. The rosettes in actinomycosis are generally more variable in shape and size and are usually larger than the uniformly small rosettes seen in actinobacillosis. Histologically, the two diseases show similar tissue and cellular reactions and can best be differentiated by the presence or absence of gram-positive organisms within the rosettes. Clinically and post mortem, these diseases may be confused with staphylococcosis (botryomycosis), tuberculosis, coccidioidal granuloma, and lesions produced by *Corynebacterium pyogenes* or other pyogenic organisms. Therefore laboratory examination is often necessary for diagnosis, which is especially important from the standpoints of prognosis and treatment.

**Recovery of *Clostridium sordellii* from cattle and sheep**, L. R. VAWTER. (Nev. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 382-385, 386).—Report is made of the morphological, cultural, and pathological characteristics of *C. sordellii*, which has been recovered six times during the last 20 yr. incident to the bacteriological examination of the tissues of animals from western Nevada—five from cattle and one from sheep. It has been found at the Nevada Station to be extremely pathogenic for laboratory animals. Three of the five cattle strains were isolated along with either *C. hemolyticum* or *C. welchii* from the liver infarcts or other tissues of cattle dead of bacillary hemoglobinuria. Another cattle strain was recovered along with *C. chauvoei* from the heart blood of a calf dead of atypical blackleg. The lesions found in calves in this outbreak consisted of a severe hemorrhagic gastroenteritis with blackleglike lesions in the pillars of the diaphragm. Recently, another strain of *C. sordellii* was recovered from a fatal post-vaccination infection among Hereford calves. One non-pathogenic strain was recovered along with *C. septicum* from a sheep dead of a braxylike disease near Reno. Although nonpathogenic, the sheep strain is culturally and serologically related to the cattle strains, reciprocal agglutination occurring between them. A fatal infection due to this organism among Here-

ford calves was encountered in March 1941 following their vaccination with a sterile formalized blackleg vaccine. A careful examination failed to disclose the presence of any other anaerobic pathogens. Since *C. sordellii* had been recovered on two occasions some 18 yr. previously from cattle tissues originating on a neighboring ranch, it is believed to be native to that and other regions in western Nevada. It possesses many of the morphological and cultural features that are common to *C. novyi*, *C. sporogenes*, and to a lesser extent *C. hemolyticum*. It is a nonmotile, sporulating anaerobic rod,  $1\mu \times 3.5\mu$ – $4.0\mu$ . Young cultures 12 to 18 hr. old are strongly gram-positive. Compared to other well-known pathogenic species of the genus *Clostridium*, the author considers *C. sordellii* one of the most dangerous and to be capable of doing all the damage characteristic of other pathogenic members of this genus.

**Experiments on the life history of the cattle lungworm *Dictyocaulus viviparus*, D. A. PORTER and G. E. CAUTHEN. (U. S. D. A.). (Amer. Jour. Vet. Res., 3 (1942), No. 9, pp. 395–400, fig. 1).**—In the work reported experimental infections of cattle with *D. viviparus* were established in calves by feeding the infective larvae. An attempt to infect a calf prenatally by feeding infective larvae to the pregnant dam gave negative results. Zinc sulfate solution (sp. gr. 1.18) with Stoll's technic (E. S. R., 63, p. 261; 76, p. 250) was employed to detect larvae in the feces and thus follow the course of infection. "Larvae appeared in the feces in from 21 to 30 days after inoculation; the prepatent period in a yearling previously parasitized was 41 days. The duration of infection, measured from the time of inoculation until larvae of the next generation were no longer being passed in the feces, varied from about 1 mo. in animals ranging from 208 to 342 days old at the time of inoculation to 4 mo. in one calf inoculated when only 6 days old. Reinfection was successful in a 4.5-month-old calf, but only a slight infection was established in one of two short yearlings that were inoculated after worms from a previous infection had been naturally eliminated. No symptoms were observed in primary infection and in reinfection of the older animals. Symptoms such as coughing, difficult breathing, and diminished appetite were seen in the more severe cases following initial inoculation in the younger calves. Intermittent diarrhea was observed in one calf having the most severe infection with lungworms. The gains in weight of infected animals were less than those of uninfected controls. There was no evidence of anemia nor significant change in the number of leucocytes in the blood of animals examined during the course of infection."

**The normal cerebrospinal fluid pressure and a method for its determination in cattle, J. F. SYKES and L. A. MOORE. (Mich. Expt. Sta.). (Amer. Jour. Vet. Res., 3 (1942), No. 9, pp. 364–367, fig. 1).**—Description is given of a method for measuring the cerebrospinal fluid pressure in bovines. Using this method, it was found that the average pressure in cattle up to 2 yr. of age was 105.1 mm. of saline. The minimum value observed was 80 mm. and the maximum 150 mm. The data suggest that the cerebrospinal fluid pressure of cattle does not vary with age for at least the first 2 yr. of life.

**Factors modifying the rate of fermentation of rumen ingesta and their possible relation to bloat in dairy cattle, N. L. JACOBSON, D. ESPE, and C. Y. CONNOR. (Iowa Expt. Sta.). (Jour. Dairy Sci., 25 (1942), No. 9, pp. 785–799, fig. 1).**—Investigations in which ingesta obtained from the cow by means of a rumen fistula were fermented in vitro and the gas collected over 24-hr. periods are reported. Having found no basis for bloat as a result of altering the environment of the bacteria in rumen ingesta, the authors have proposed a theory based upon the physical effect of the feed. This theory, however, has not been verified experimentally.

**Analyses of gas and ingesta of bloated cattle**, R. W. DOUGHERTY. (Oreg. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 401-402).—All gas and ingesta samples taken shortly after death from steers that had died of acute tympanites had relatively high concentrations of hydrogen sulfide, and all ingesta samples were relatively high in histamine content. Existing pressures in the rumino-reticular cavities of the dead animals varied between 72 and 75 mm. of mercury.

**A study of the administration of sulfanilamide to the normal dairy cow**, I. ZIPKIN, A. K. ANDERSON, and W. T. S. THORP. (Pa. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 329-335, figs. 2).—Report is made of a study of (1) the free and total sulfanilamide content of the blood and milk following the administration of different doses of this drug to normal dairy cows and (2) of the effect on the blood picture, including the erythrocyte, leucocyte, and differential counts and the hemoglobin content. On the low level of dosage 69 percent of the total sulfanilamide found in the milk was present as the conjugated compound, whereas 37 percent was present in the blood as the conjugated derivative. On the high level of dosage 56 percent of the total sulfanilamide was conjugated in the milk, whereas little conjugated sulfanilamide could be detected in the blood on the same level of dosage. Free sulfanilamide distributed itself approximately equally in the blood and milk on both levels of dosage. A slight anemia was produced, with a maximum reduction in the erythrocyte count and in the hemoglobin value of about 20 percent. On the low level of dosage a slight leucocytosis was observed, while on the high level of dosage a marked leucopenia was produced, representing a decrease in leucocytes of 60 percent. A decided increase in the percentage of neutrophils was noted. In addition, atypical and degenerated leucocytes were found in the blood during the height of sulfanilamide administration. The milk production was found to vary inversely with the excretion of sulfanilamide in the milk. The milk flow was reduced by as much as 82 percent. An average decrease in weight of 8.6 percent resulted from the ingestion of sulfanilamide. Individual differences in tolerance toward sulfanilamide were noted in the cows throughout the course of study.

**Homogenized sulfanilamide-in-oil in the treatment of bovine mastitis**, C. C. PALMER. (Univ. Del.). (*North Amer. Vet.*, 23 (1942), No. 12, pp. 776-779).—A 35-38-percent suspension of sulfanilamide in liquid petrolatum proved to be very satisfactory for introduction into the udder. If a 35-percent suspension is employed each 50 cc. will contain 17.5 gm. of sulfanilamide, which is the correct dose for each infected quarter in an udder of average size. It is recommended that such injections be made once daily for 3 or 4 days. Next in importance is staphylococcal mastitis, which is more important than streptococcal mastitis in some herds. *Staphylococcus aureus* may cause a mild form of the disease that is clinically very similar to streptococcal mastitis. It is also capable of causing an acute mastitis accompanied by extreme toxemia, which may terminate in udder necrosis. Good results have been obtained in treating these cases with sulfanilamide-in-oil when the mastitis is mild or chronic, or when there are marked symptoms of mastitis and toxemia as indicated by elevation of body temperature and loss of appetite. In cases showing symptoms of udder necrosis (gangrene) the treatment is of little or no value. Those cases of necrosis caused by pathogenic strains of *S. aureus* occur most frequently at calving time. If pathogenic strains of *S. aureus* are found it is usually possible to destroy the infection by the sulfanilamide-in-oil treatment and thus prevent the very serious mastitis which otherwise develops soon after calving.

Mention is made of other bacteria capable of causing mastitis which clinically are usually acute. The most common of these are *Escherichia coli*,

*Pseudomonas aeruginosa*, and *Corynebacterium bovis*. Treatment of these forms is not very satisfactory.

**The udder and mastitis**, [I], II, W. E. PETERSEN. (Univ. Minn.). (*Holstein-Friesian World*, 39 (1942), Nos. 17, pp. 949-950, 986-987, fig. 1; 18, pp. 1001-1002, figs. 2).

**The results obtained with tyrothricin in the treatment of 157 cows with streptococcic mastitis**, C. S. BRYAN, M. L. WELDY, and J. GREENBERG. (Mich. Expt. Sta.). (*Vet. Med.*, 37 (1942), No. 9, pp. 364-369, figs. 8).—In the treatment of 157 cows with streptococcic mastitis each infected quarter was infused with 150 mg. of tyrothricin. This resulted in 142 becoming free from the streptococcic infection. Three cows did not drop in milk production upon treatment, while 64 produced from 1 to 50 percent less milk and only 6 cows of 73 dropped between 50 and 90 percent in milk production. All returned to approximately normal milk flow within 21 days. The period of abnormal milk production after treatment of 73 cows was less than 5 days for 57 cows and more than 5 days but less than 14 days for the remaining 16 cows. The standard plate bacteria count of milk produced by 10 cows before treatment and upon recovery after treatment yielded reductions in bacteria count varying from 30 to 90 percent.

**Laboratory methods for differentiating *Trichomonas foetus* from other protozoa in the diagnosis of trichomoniasis in cattle**, B. B. MORGAN and L. E. NOLAND. (Wis. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 11-15, figs. 21).—Description is given of the procedure to be followed in the microscopic differentiation of *T. foetus* from other protozoan organisms commonly encountered in material received for diagnosis, together with the technic employed in preparing the artificial cultures.

**Studies on the etiology and pathology of calf pneumonia**, W. T. S. THORP, J. F. SHIGLEY, and M. A. FARRELL. (Pa. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 342-349, figs. 10).—Report is made of histopathological studies of 28 cases of calf pneumonia and bacteriological studies of all but 4. "Hemophilic-like bacteria were consistently isolated from the cases examined. Attention has been called to the marked similarity of the gram-negative organism isolated to *Hemophilus suis*. Attempts to introduce pneumonia in calves by inoculations of the organisms did not meet with consistent or conclusive results. Histopathological studies reveal a characteristic broncho-pneumonia similar to that reported [by Thorp and Hallman (*E. S. R.*, 81, p. 282)]. However, the degree of injury to the bronchioles appeared more severe in the cases that were observed in this study. The numerous giant cells and large mononuclear phagocytes observed in cases of acute pneumonia appear to be in proportion to the extent of injury and necrosis in the terminal and respiratory bronchioles."

**[Work with sheep parasites by the Georgia Station]** (*Georgia Sta. Rpt.* 1942, pp. 50-51).—The work of the year (*E. S. R.*, 86, p. 831) was again related to worm control in sheep and control of the sheep tick and the sheep louse *Trichodectes ovis*.

**The relationship of diet to the development of haemonchosis in sheep**, J. H. WHITLOCK, H. P. CALLAWAY, and Q. E. JEPPESEN. (Kans. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 34-35).

**Field test of various anthelmintics used for the treatment of haemonchosis**, J. H. WHITLOCK. (Kans. State Col.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 386-391).—Tests conducted on heavily infected farm flocks of sheep in north-central Kansas during the spring, summer, and fall of 1941 to determine the comparative efficiency of anthelmintics in the control of *Haemonchus contortus* are reported. The results gave no evidence that the addition of formalin and

arsenic, nicotine sulfate, or formate to soluble copper salts increased the efficiency of copper sulfate against this parasite. Phenothiazine is significantly more effective than copper compounds although it sometimes fails in acute cases of stomach worm disease, but the results obtained indicate that it does not fail as often as copper sulfate. This led the author to recommend it guardedly for treatment of acute hemonchosis, and since it is expensive and difficult to administer it is considered a good policy to use it only in the acute cases within an infected flock. Copper sulfate should be expected to remove satisfactory numbers of *H. contortus* in the majority of cases. Because of the low cost, toxicity, and ease of administration 10 percent copper sulfate solution in the dosage of 1 cc. per 10 lb. of body weight, preceded by from 1 to 2.5 cc. of the same solution depending upon weight, is the treatment of choice whenever the problem consists solely of removing *H. contortus*. This means that it is recommended in chronic hemonchosis and as the drug to be used in monthly treatments to prevent the disease.

**Preventing lamb losses**, F. THORP, JR., (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 136-137).—The importance of and means of preventing losses of lambs from diseases are considered.

**Parenchymatous goiter in newborn goat kids**, W. G. LOVE. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 101 (1942), No. 789, pp. 484-487, figs. 6).—A brief discussion of normal and hyperplastic thyroid glands is followed by a report of four cases of thyroid enlargement in newborn kids born of dams on a *Brucella melitensis* exposure experiment. Three of the kids were born dead, and the fourth died shortly after birth. Gross and histopathological studies received consideration, and upon these bases a diagnosis of parenchymatous goiter was made. The probable etiology of the disease is suggested.

**Parasites of moose in northern Minnesota**, O. W. OLSEN and R. FENSTERMACHER. (Minn. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 403-408).—This digest includes a key for the field identification of the parasites known to occur in North American moose and a list of 26 references to the literature cited.

**The longevity of encephalomyelitis immunity induced in horses by vaccination**, H. W. SCHOENING, M. S. SHAHAN, L. T. GILTNER, and O. L. OSTEN. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 102 (1943), No. 790, pp. 18-21).—Three horses receiving two subcutaneous 10-cc doses of western equine encephalomyelitis vaccine and two of three horses given the same vaccine intradermically in two doses of 1 cc. each survived intracerebral inoculation of encephalomyelitis virus 8 mo. afterward. The results were the same when the same number of similarly treated horses were exposed 13 mo. after vaccination, though there were indications that the immunity was waning at the later time. A brief general discussion of the subject of vaccination against the disease is offered.

**Studies on congenital transmission of equine infectious anemia**, C. D. STEIN and L. O. MORT. (U. S. D. A.). (*Vet. Med.*, 37 (1942), No. 9, pp. 370-377, figs. 4).—Following a review of the knowledge of hereditary transmission of infectious anemia, evidence is presented indicating that transmission of the disease from an infected mare to its offspring may occur during intrauterine life. The findings reported indicate that (1) the milk secretion of mares and the semen of stallions affected with infectious anemia may contain the virus; (2) a normal colt may acquire the disease from nursing an infected mare; and (3) an inapparent form of the disease may be set up in a normal horse by the injection of tissue suspensions from a colt so infected. The presence of the virus in the blood of a carrier that had shown no clinical symptoms for more than 6 yr. subsequent

to acquiring the disease was demonstrated. Attempts to transmit the disease by coltus, by repeatedly breeding a normal stallion to two infected mares, were negative.

**Abnormal capillary resistance in swine suffering from an inherited bleeding disease, E. T. MERTZ.** (Mo. Expt. Sta.). (*Amer. Jour. Physiol.*, 138 (1942), No. 1, pp. 136-139, fig. 1).—The results of the work conducted give evidence that the capillary resistance in swine suffering from an inherited bleeding disease is abnormally low.

**Sulfaguanidine in the treatment of infectious enteritis in swine, H. C. H. KERKAMP and M. H. ROEPKE.** (Univ. Minn.). (*Vet. Bul. Lederle*, 11 (1942), No. 2, pp. 35-36, fig. 1).—Preliminary tests of sulfaguanidine in enteritis in swine indicate that an effective dose is within the range of 0.165 to 0.33 gm. per kilogram of body weight, and no ill effects were noted with dosages below 0.66 gm. In general, the diarrhea was checked and the feces returned to normal consistency by the fourth or fifth day, and the treatment was continued for an additional 3 or 4 days before the animals were released. A corresponding improvement in physical condition occurred.

**A study of thiamine deficiency in swine, together with a comparison of methods of assay, M. M. WINTROBE, H. J. STEIN, M. H. MILLER, R. H. FOLLIS, JR., V. NAJJAR, and S. HUMPHREYS** (*Bul. Johns Hopkins Hosp.*, 71 (1942), No. 3, pp. 141-162, figs. 6).—In the experiments conducted thiamin deficiency was produced in pigs given crystalline vitamins as their chief source of the vitamin B complex. "The chief symptoms observed were anorexia, vomiting, dyspnea, cyanosis, and great weakness. The symptoms of cardiac failure appeared suddenly and unless thiamin was given resulted promptly in death. Unexpected death occurred in some instances without dyspnea and cyanosis having been observed. Impairment of growth was not a prominent sign in pigs dying early of acute thiamin deficiency. In all the animals dying as the result of thiamin deficiency, focal necroses of the myocardium were observed. No neurological symptoms were observed nor were any degenerative changes in the nervous system found even in animals in which thiamin deficiency of long duration was produced."

**Distemperoid virus as an immunizing agent against canine distemper, O. STADER and R. R. SLAUGHENHAUPT** (*North Amer. Vet.*, 23 (1942), No. 12, pp. 782-784, 790).—Report is made of the use of the so-called distemperoid virus, consisting of true canine distemper virus serially passed through a sufficient number of ferrets (50-60) to eliminate its pathogenicity for canine tissue. This virus vaccine (distemper vaccine—ferret origin—Green method) has been produced after 15 years' research by R. G. Green with a view to controlling distemper in the fox, over 500,000 of which and several thousand dogs having been immunized. The results of the authors' vaccination of 385 dogs in four groups, according to the milligram dose received, are reported. It was found that dogs, unlike foxes, require much larger doses (15 mg.) in order to develop rapid immunity. This product has in no instance caused true distemper, but when the dose is small (2.5 mg.) and immediate exposure to true distemper follows, the immunity response is not sufficiently rapid in some instances to prevent the true virus from gaining control. It is entirely feasible when 15-mg. doses are used to immunize dogs and hospitalize them immediately. When 15-mg. doses are used the clinical reactions are so slight as to go unnoticed by the owner in most instances. In the cases reported the immunity produced appears to be of long duration, probably lifelong.

**Distemper inclusion bodies, E. A. WATSON and P. J. G. PLUMMER** (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 350-357, fig. 1).—The eosinophilic cell-inclu-

sion bodies here described are frequently found present in certain tissues of ferrets, foxes, and mink when these animals are in the end stages of or dead from experimental distemper, or in natural enzootics of the disease. "The inclusions were most frequently seen in the epithelium of the urinary tract (kidney, pelvis, and bladder), occasionally in the epithelium of the bile ducts of the liver and of the gall bladder, but never in the tissues of the brain, trachea, lungs, spleen, stomach, and intestines. Cell inclusions were detected in from 25 to 65 percent of infected ferrets, the percentage varying in groups infected with different virus strains, and in approximately 33 percent of mink and foxes. Positive findings could not be made in ferrets killed during the incubative stage of infection, but were obtained in increasing number and percentage as the disease advanced to the final stage and were highest in animals which actually succumbed to it. The inclusions were almost invariably intracellular and cytoplasmic. Very rarely an inclusion was seen which might have been intranuclear or only apparently so by its location on or under the cell nucleus. Only negative findings were obtained in ferrets artificially immunized with distemper viruses and killed in from 2 to 16 days after a later inoculation of virus and in immunized foxes similarly treated and killed after time intervals of 50 to 180 days. Cell inclusions similar in all respects to those found in 1 of a group of 11 normal healthy ferrets were taken from a colony rigidly isolated from infection and in 2 mink which died of a disease not caused by distemper."

The use of grain containing tarweed (*Amsinckia intermedia*) seed as poultry feed, E. C. McCULLOCH. (Wash. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 101 (1942), No. 789, pp. 481-483).—In further studies of tarweed (E. S. R., 85, p. 823) the seed of this plant in the amounts occurring in unscreened western wheat was not toxic for poultry. Even 14 percent of the seed in the ration was not toxic when fed for as long as 100 days during the period of most rapid growth. However, feeding experiments extending over much longer periods and to laying hens and breeders must be conducted before the possibility of toxic effects from the feeding of this seed to poultry is eliminated.

Combating chick diseases, E. JUNGHER. (Univ. Conn.). (*Northeast. Poultry Prod. Council, Ann. Mtg. Proc.*, 1941, pp. 77-81).

Studies of the hemoglobin content of chicken blood and evaluation of methods for its determination, R. A. BANKOWSKI. (Univ. Calif.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 373-381, figs. 2).—Comparative studies of the adaptability and the relative accuracy of the Dare, Haden-Hauser, and Sheard-Sanford methods, the modified Newcomer method, and new photometric acid hematin and photometric alkaline hematin methods for the determination of hemoglobin in chicken blood are reported. "The modified Newcomer method and the new photometric acid hematin method gave the most consistent results and are considered as most suitable for the determination of hemoglobin in chicken blood. The hemoglobin content of the normal 6- to 8-week-old White Leghorn chickens was established as  $9.71 \pm 0.83$  gm. and  $9.83 \pm 1.00$  gm., respectively, by the modified Newcomer and photometric acid hematin methods. The Dare, Haden-Hauser, and Sheard-Sanford methods were found to be unsatisfactory for determination of hemoglobin in chicken blood. The photometric alkaline hematin method gave variable hemoglobin values which averaged 2.25 gm. per 100 cc. of blood higher than those obtained with the modified Newcomer and photometric acid hematin methods. Both the variability and higher hemoglobin values are believed to be due to the presence of nonhemoglobin constituents of blood in the alkaline hematin solution."

A list is given of 57 references to the literature.

**Suggestions for the use of sulfathiazole in the prevention and treatment of infectious coryza (*H. gallinarum*),** J. P. DELAPLANE. (R. I. Expt. Sta.). (*Vet. Bul. Lederle*, 11 (1942), No. 2, pp. 43-45, figs. 2).—Sulfathiazole was effective in the prevention and spread of *Hemophilus gallinarum* and in treating infected birds.

**Studies on the production of specific antibodies against the agent of fowl leucosis,** C. D. LEE. (Iowa State Col.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 9, pp. 336-341).—"Immunization of ducks and turkeys by repeated injections of leucosis material produced a serum capable of inhibiting or neutralizing the infective agent or infective power of leucosis cells. The immune serums from ducks and turkeys not only neutralized the cell-free agent but the cell-bound agent as well. Immune serums from ducks injected with myeloid leucosis blood were also able to inhibit or neutralize the agent of the neural type of the fowl leucosis complex. Serums from ducks injected with the neural type of fowl leucosis were able to inhibit the development of the myeloid leucosis type. Neutralization of the agent of one type or form of the disease by duck or turkey serum produced by a series of injections of infectious material from lesions of a different form or type of the complex more closely indicates the possibility of a single etiology. Blood from turkeys or ducks that were not injected with material from cases suffering from the fowl leucosis complex did not contain inhibitors for the agent of fowl leucosis. The blood from recovered birds or from birds that failed to take when inoculated with viable material was able to neutralize the agent of fowl leucosis."

**Spontaneous ornithosis (psittacosis) in chickens the cause of a human infection,** K. F. MEYER and B. EDDIE. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 522-525).

**A new coccidium, *Elmeria brunetti* n. sp., pathogenic for chickens,** P. P. LEVINE. (Cornell Univ.). (*Jour. Bact.*, 44 (1942), No. 6, pp. 722-723).—Under the name *E. brunetti* description is given of a new species of coccidium pathogenic for the chicken. The "sporulated oocysts range in size from 18.1 $\mu$ -24.2 $\mu$  in width  $\times$  20.7 $\mu$ -30.3 $\mu$ , the average being 21.7 $\mu$  $\times$ 26.8 $\mu$ . Oocysts appear in the feces at the end of the fifth day after the infective feeding. Oocysts and developmental forms are present in the lower half of the small intestine and in the rectum, cloaca, and caeca. In severe infections the upper half of the small intestine may also be involved. The oocysts are discharged periodically, the greatest elimination being between 9 a. m. and 3 p. m. No gross lesions are found in light infections. Moderately heavy infections produce a catarrhal enteritis with blood-tinged mucous exudate. Quite often there appear on the mucosa short, red, horizontal streaks that extend as ladderlike rows along the length of the affected parts. Coagulation necrosis and sloughing of the mucosa occur in severe infections. Frequently the necrotic mucosa takes the form of a dry, diphtheritic membrane lining the intestinal tract. These lesions may be confluent or focal. The dilated portion of the caeca is usually without lesions aside from erythema of the mucosal ridges. On the other hand, the constricted, proximal, tubular entrances to the caecal pouches become markedly dilated and plugged by short caseous cores." Cross-immunity tests indicate that it is different from previously described species with which it might be confused. Sulfaguanidine when fed to chickens in the proportion of 0.5 percent of the ration prevented infection. A natural outbreak in a commercial flock of coccidiosis proven to have been caused in part by *E. brunetti* was studied.

**Hexamita sp. from the ringed-neck pheasant,** W. R. HINSHAW and E. McNEIL. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 101 (1942), No. 789, p. 503).—Report is made of the finding of a species of *Hexamita* morphologically

indistinguishable from *H. meleagridis* in two 8-week-old pheasants (*Phasianus torquatus*) in a pen from which the disease had spread to three other pens. The symptoms described were loss of coordination without noticeable loss of appetite and no diarrhea. In most cases the birds died before symptoms were observed. The mortality in each pen exceeded 50 percent. Reference is made to a case of *Heramita* in a month-old white peafowl, reported by C. U. Duckworth and A. G. Boyd.<sup>2</sup>

## AGRICULTURAL ENGINEERING

**Introduction to agricultural engineering**, H. E. PINCHES (*Ann Arbor, Mich.: Edwards Bros., 1942, 2. ed., pp. [5]+89, figs. 61*).—The author's purpose is not that of providing another textbook of operation and repair of farm machines, but rather to present and to interpret some principles which underlie the practical and the specialized. The approach is analytical, showing methods of thinking and providing a preliminary acquaintance with a wide variety of problems, in order that an interest may be aroused and a ground work laid from which the student can proceed to more penetrating and independent applications of certain fundamental physical principles to problems of agricultural industry and rural living. An introductory chapter defines the scope of agricultural engineering, dividing this field into three categories—soil and water control, structures, and energy control—indicating the coverage of each category and giving some practical illustrations in each instance. The remaining contents are in two parts, dealing, respectively, with force relations and with energy states and transformations. Part 1 consists of chapters on what are forces and how do they act, the action of external forces on bodies, the action of internal forces, and balancing external and internal forces. Part 2 takes up power and work, power and machinery in agriculture, energy states and transformations, heat, electricity in agriculture, hydraulics, and levels and leveling.

**Wartime prices as related to the work of agricultural engineers**, R. B. CORBETT. (Md. Expt. Sta.). (*Agr. Engin., 23 (1942), No. 11, pp. 341-343, 346, figs. 2*).—This is an economic discussion supporting and extending the views of R. W. Carpenter and A. V. Krewatch, set forth in the paper noted below, that the prevention of an economic depression in the period of price collapse tendency following the war is an important responsibility of agricultural engineers, who should prepare now plans for improved farm plant equipment and conveniences as a part of the provision for reemployment of the great numbers now occupied with war work or military service.

**Agriculture's big building job**, R. W. CARPENTER and A. V. KREWATCH. (Univ. Md.). (*Agr. Engin., 23 (1942), No. 11, pp. 344, 346*).—The viewpoint of the authors of this paper is basically the same as that of the discussion above noted, but emphasis is placed more specifically upon preparation for the improvement or replacement of farm structures. "It is proposed that the land-grant colleges and universities and the U. S. Department of Agriculture be given the facilities necessary to carry on an intensive program of education, demonstration, and technical assistance in the design, remodeling, and construction of farm homes and buildings. . . . At present, less than one-fourth of the States devote the equivalent of one man's full time to extension work with farmers or with county agents on farm building construction problems. It appears that the annual expenditures for specialized agricultural engineering extension work on farm buildings does not exceed \$50,000, and that the total amount spent for direct extension and research work in this field by the State agricultural colleges and

<sup>2</sup> Calif. Dept. Agr. Bul. 30 (1941), No. 4, pp. 440-456.

the U. S. Department of Agriculture (exclusive of F. S. A. and R. E. A.) does not exceed \$200,000 per year. This is about 3 ct. per farm per year."

[Investigations in agricultural engineering by the Kansas Station]. (Partly coop. U. S. D. A.). (*Kansas Sta. Bier. Rpt. 1941-42*, pp. 26-27).—These included a study of methods of harvesting and storing grain sorghums and factors influencing the quality of wheat during storage, both by F. C. Fenton.

[Agricultural engineering investigations by the Montana Station]. (Partly coop. U. S. D. A. et al.). (*Montana Sta. [Bien.] Rpt. 1941-42*, pp. 33-35).—Irrigation studies, conservation of flood water for range improvement, and the snow survey are among the topics to which brief reference is made by O. W. Monson.

[Agricultural engineering investigations by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 429 (1942)*, pp. 3-6, figs. 2).—Reported by A. W. Clyde are experiments showing that the tractor operator may waste one-third of fuel, pressure on landside increases plow draft, and stop-hitches protect plows from breakage. Electric appliances were found, by R. U. Blasingame, to save much farm labor. Devices specifically mentioned are plug-in water heaters, electrically heated pails, use of heating cable for protection of water pipes against freezing, and electric ventilation fans.

Industrial quality of public water supplies in Georgia, 1940, W. L. LAMAR (*U. S. Geol. Survey, Water-Supply Paper 912 (1942)*, pp. III+83, fig. 1).—For each of the public supplies are given data indicating the ownership, source, treatment, storage, and distribution of the water. A total of 157 complete mineral analyses show the chemical character of the water at each place. At places where the water receives chemical treatment other than chlorination, analyses for both the raw and the finished water are recorded. The extremes in total dissolved solids for the ground waters as furnished to consumers were 24 and 1,030 p. p. m.

Making sandbags last longer (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1942*, p. 9).—A standardized technic was developed for determining the ability of certain fungi and bacteria to break down cellulose. This rapid technic may be adaptable to the testing of the effectiveness of rotproofing treatments and making improvements in them.

Soil erosion control practices that meet wartime needs, R. C. HAY. (Univ. Ill. coop. U. S. D. A.). (*Agr. Engin., 23 (1942)*, No. 11, pp. 353-355, figs. 3).—Average corn yields on farms in four counties were found definitely greater when the crop was grown on the contour in 1941. The system for the construction of terraces with a plow is described, and its advantages and disadvantages are summarized. Advantages of the plow terrace method are the facts that regular farm equipment available on nearly every farm can be used, only one operator is required, farmers quickly learn the use of this method, farmers can readily rebuild and maintain terraces by this method, part of the field can be contour plowed while terraces are being constructed, and terraces so constructed are generally well shaped to work with farm machinery. The disadvantages of the method are that terraces constructed have lower ridge heights than usually recommended, i. e., not over 15 in. before settling; steep slopes, over 8-10 percent, cannot be terraced satisfactorily; and construction is slower than by some terracers.

A new development described as the formless concrete flume has, as the essential features making it a structure satisfactory for gully control under both normal and wartime conditions, the advantages of low materials cost, from one-third to one-fourth that of the regular notch spillway dam; low labor require-

ment; permanency; simplicity of construction; the use of high-strength concrete; design as a sloping flume, which requires no support of a vertical wall of earth; and construction without reinforcing steel. On most farms sound soil and water conservation and erosion control practices will make it possible for farmers to contribute more to the war effort, since these practices fit definitely into such a program.

**Concrete with minimum of steel, W. G. KAISER** (*Agr. Engin.*, 23 (1942), No. 11, pp. 347-348, 351, figs. 2).—The author holds that most concrete farm improvements can be built without the use of reinforcing steel. It is not needed in footings and foundation walls under average conditions, or in the construction of farm-building floors, feeding floors, paved barnyards, runways, sidewalks, and many other flat surfaces. In the case of floors which are likely to be hauled over with heavy loads (or where the floor is built on a new fill), it is good practice to make the concrete slab 6 in. thick. To control cracking, large paved areas should be laid in sections with construction joints extending through the full thickness of the concrete. To make sure that there will be no bond between adjacent sections, a strip of waterproof building paper should be placed against the form face and left in place when the form is removed. Sections 10 ft. square should be satisfactory for most paved areas. For some structural purposes, however, reinforced concrete is required to sustain heavy loads, live and dead, and provide the necessary structural stability as in suspended floors in barns, granaries, and other buildings; walls for large grain bins and for silos; flat slab roofs over underground storage cellars, water storage tanks; check dams and flumes; and some other structures; but while it may not be feasible to eliminate reinforcing steel in such construction, the quantity of steel used can often be very substantially reduced by selecting designs which permit its most efficient utilization. As an illustration of this, the author lists the steel requirements of seven concrete floor designs ranging in steel demand from a two-way slab construction using 3.70 lb. per square foot to a flat slab design needing but 2.13 lb. per square foot. The last-named construction type (the most economical as well as the lowest in steel requirement) is described specifically as a girderless solid slab with drop panels, column capitals, and two-way reinforcement. Increase of allowable stresses on the basis of the improved strength of modern concretes due to better cements, reduction of wall reinforcement needs by provision of more control joints, and other steel-saving measures are also noted.

**A tractor level for laying out contour lines, O. J. TRENARY and W. S. PIERCEY.** (Wash. State Col.). (*Agr. Engin.*, 23 (1942), No. 11, p. 356, figs. 2).—The level is made up of a 5-ft. piece of 2-in. pipe, on each end of which is an elbow and a 10-in. standpipe. The tops of the standpipes are connected by a piece of  $\frac{3}{4}$ -in. pipe, which closes the water channel. The device is mounted on top of the tractor so that it is parallel to the direction of travel of the tractor at all times. The instrument is filled with water so that it rises in the standpipes to one-half their height when the tractor is level. One standpipe is made like the water gage of a boiler so that the water level can be noted. As one end of the level is raised above the other, there is a vertical movement of water in the glass tube, and it is calibrated in degrees so that the operator may easily note the exact grade at which the tractor is operating. By closing two valves, one on either side of the standpipe containing the glass tube, the rapid movement of the water column due to shock and vibration may be damped until there is a gradual movement. The amount of damping may be adjusted to suit the operating conditions. The tractor level is constructed largely from common hardware items. The bottom section consists of a 2-in. piece of pipe, with a

common shut-off valve near the water-glass end. The air line across the top is a piece of  $\frac{3}{8}$ -in. pipe with a common shut-off valve near the water-glass end. A detail sectional drawing shows how the glass tube is fastened inside the  $\frac{3}{4}$ -in. pipe so there will be no leaks at the top or bottom. Common graphite asbestos water pump packing is used and provides a good seal.

**Problem of estimating farm machine needs,** O. W. MEIER (*Agr. Engin.*, 23 (1942), No. 11, pp. 352, 355).—This is a brief discussion by the chief of the farm machinery and equipment unit of the Office of Civilian Supply, War Production Board. The author finds that in attaining peak production farmers in general did not lack equipment. Farm machinery sales in 1942, combining production allowed under L-26 and inventories carried over from the previous year, were among the highest on record. Repairs were adequate with few exceptions, and existing machinery is deemed in unusually fine repair. The farm labor situation developed some shortages, but these were primarily in the hand harvesting of crops and hence not of the type which can be alleviated by additional new machinery. The possibilities of obtaining more effective use of farm machinery through cooperative and custom use have remained virtually untapped. Failure to attain 1943 production goals is viewed as less serious than would have been the case had 1942 harvests been less plentiful. Depending upon the course of the war, the materials situation may improve or worsen. It is not impossible that production of more civilian commodities using steel will be cut out altogether, and that the program for farm equipment may be set at even lower levels than the lowest yet recommended. It is imperative that effective programs be initiated to insure the maintenance and maximum use of the equipment which we now have.

**Duty of field machines,** E. G. McKIBBEN, E. O. HEADY, and J. A. HOPKINS (Iowa Expt. Sta. coop. U. S. D. A. et al.). (*Agr. Engin.*, 23 (1942), No. 11, pp. 357-359, 366-368).—The data dealt with were obtained from about 3,000 farms, constituting about 1.5 percent of the Iowa total. A detailed tabulation shows the use in 1941 of between 35 and 40 types with relation to farm size, and the percentage distribution of a two-bottom tractor plow, per bottom; two-row corn planters (horse-drawn and tractor-drawn), per row; corn pickers (single-row and two-row), per row; and 5- and 6-ft. combines, per foot. The daily performance of some machines was not uncommonly as low as 50 percent of their theoretical capacity calculated on the basis of width and operating speed, but it would appear probable that for most of the machines annual duties of from 150 to 200 percent of the average annual use given should be both feasible and economic. Where farms are larger and topography is favorable, careful management should result in even higher annual duties. The possibility for improvement over the average duty reported is probably not so great for 5- and 6-ft. combines and two-row corn pickers, where programs of extensive custom operation are already the rule. The possibility of custom use probably offers the best possibility of extending the average annual duty of field machines.

**Protection for fractional horse power motors,** D. E. WIAIT (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 132-135, figs. 3).—The commercially available thermostatic devices are briefly described, together with substitute devices which may be used when the commercial protectors are not available or when the motor is not adapted to their use. One of these consists simply in placing a time-delay fuse of the amperage capacity next above that stated on the name plate of the motor in series with the socket into which the motor is plugged. When time-delay fuses cannot be had it is recommended to insert two sockets in parallel in one side of the motor supply, fitting one with a fuse capable of carrying the starting current and the other with a fuse of smaller capacity. The motor is

then started through the heavier, but run after starting through the lighter, of these two fuses by unscrewing the heavier one from its socket.

**Trends in hay production, C. B. RICHEY.** (Ohio State Univ.). (*Agr. Engin.*, 23 (1942), No. 11, pp. 345-346, figs. 5).—The author presents, in graphic form and in brief discussion of the significance of the figures shown, data concerning the varieties of hay produced in the United States and the even wider variation in methods of taking up, transportation, and storage. It was observed that equipment used in some parts of the country may be entirely foreign to other sections, and that there are corresponding variations in efficiency in terms of man-hours per ton, "probably represented by the load by hand—wagon—store by hand—barn combination at one extreme and the power buck rake—stacker—stack combination at the other. The hay loader—wagon—fork or sling—barn combination still accounts for more hay than any other method, although farmers are becoming increasingly dissatisfied with it."

**Results of a study of trends in methods of hay storage, G. R. SHIER ET AL.** (*Agr. Engin.*, 23 (1942), No. 11, pp. 349-351, fig. 1).—Numerous methods and combinations of methods are taken up in a general review.

Chopping saves space and some labor in handling the hay for feeding. It does not reduce weather hazards appreciably, however, and may require more equipment and more labor at haymaking time, although equipment such as the pick-up field choppers supplemented by convenient elevating equipment does not involve a large labor force. Chopped hay reduces fire hazard somewhat in that chopped hay tends to smolder; and fire in chopped hay can often be extinguished or removed from a barn before the building is lost. There is no evidence that chopping hay improves the quality of hay over hay made long, although it may heat and develop a cooked flavor that animals learn to like. Advantages and disadvantages of the ensilage of chopped hay are noted. In mow curing of field-chopped and partly cured hay some difficulty in forcing enough air through the stored mass, due to the increased volume weight resulting from chopping, was encountered, but with laterals more closely spaced (3 ft.) and the use of a volume of air per pound equal to that supplied to long hay it is held possible that the method may be quite successful.

The need for a pick-up baler operating as simply as does the grain binder is emphasized, the mow drying of long hay by forced draft air at natural temperature is briefly discussed, and the importance and probable effect on hay storage methods of the buck or sweep rake is emphasized. In conclusion the report takes up briefly the suggestion that present rapid changes in agricultural methods do not justify the construction of long-lived buildings, but stresses the value of conveniently arranged, durable, long-life buildings that are a national asset in a difficult time.

**Potato storages for Michigan, A. D. EDGAR, C. H. JEFFERSON, and E. J. WHEELER.** (Coop. U. S. D. A.). (*Michigan Sta. Spec. Bul.* 320 (1942), pp. 39, figs. 16).—Temperature and humidity requirements for best results in potato storage are discussed, together with some other factors to be taken into consideration in designing for new construction or for remodeling. Among handling methods and devices dealt with is an experimental portable elevator conveyor having a 16-in. belt and capable of moving the potatoes either horizontally or upward at an angle to the top of an 8-ft. pile. Work alleys at two levels in the storage building are among other devices intended to lessen mechanical damage in placing the crop in storage. Working drawings for the construction of a 24- by 24-ft. storage with concrete floor, concrete side walls rising from 3 ft. 10 in. below ground level to 1 ft. above ground, either gambrel or gothic-type roof, air-circulation ducts, fill-type insulation, etc., are reproduced, and tabulated cost estimates are given for the remodeling of old storage buildings.

The ceiling drip pans, planned condensation against vapor-protected surfaces, and better-planned circulation and ventilation provisions are emphasized.

**Cost of operating mechanical milk coolers,** R. L. WITZ. (Coop. U. S. D. A.). (*Indiana Sta. Cir.* 271 (1942), pp. 7, figs. 3).—The results of 21 2-week tests on 7 electric motor-driven milk cooling units showed an average cost of 2.6 ct. per 10 gal. of milk cooled or 5.8 ct. per 1,000 degree-gal. The results of 14 2-week tests on 6 gasoline engine units showed an average cost of 4.0 ct. per 10 gal. or 10.8 ct. per 1,000 degree-gal. It was shown that the competence of the operator is an important item in the operation of manually controlled units and has considerable effect on the cost of cooling with the gasoline engine units. The cost of operation was found to be affected by the difference between the air temperature and water temperature in the storage tank to a degree such that the air temperature surrounding the milk cooler should be reduced as much as possible for economical operation. Coolers operated approximately at full capacity were most economical. Insulation was shown to be necessary to keep operating costs at a minimum.

**The electric pig brooder,** H. H. SMITH (*Farm and Home Sci.* [Utah Sta.], 3 (1942), No. 4, p. 12, fig. 1).—The brooder described consists of a platform about 40 in. long and 10 in. from the floor built in one corner of the pen and heated by a 100-w. bulb placed over a circular opening about 1 ft. in diameter and covered with a dishpan to serve as a reflector. The platform may be of 1-in. lumber but 2-in. material is considered better, and fencing is to be provided to prevent the sow from getting up on it.

**Lamp-type electric pig brooder** (*Oregon Sta. Bul.* 401 (1941), p. 30, fig. 1).—An inexpensive brooder is pictured.

**[A solar water heater],** J. K. ALVIS (*Puerto Rico Sta. Rpt.* 1941, pp. 23-24).—For a family of four a 40-gal. standard range boiler connected to an absorber coil made up of 160 ft. of  $\frac{3}{4}$ -in. black pipe will ordinarily be sufficient. The storage tank should be mounted considerably higher than the absorber unit and must be completely insulated with a dry organic material such as sawdust or sugarcane bagasse. The heating coil can be economically laid in a space 40 ft. long in two parallel circuits. On bright days when the usual temperature was about 75° F., water temperatures of 140° have been obtained.

**Orchard and potato spray rigs in rural fire protection,** C. H. JEFFERSON and G. AMUNDSON (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 94-99, figs. 4).—These farm spray rigs are so similar in their effect upon the water discharged from them to the commercial so-called "fog gun" that they can be used for fire-extinguishing purposes, the mist of minute droplets being much more effective per gallon of water applied and much more rapid in stopping combustion than are solid streams. The lessening of the secondary water damage by the use of spray rather than stream is also noted. The enormously increased water surface in the spray, as compared with that of the solid stream, with the consequent increase in cooling and fire-smothering effect, is explained and is illustrated by derivation of a formula for increase in surface area with decrease in droplet diameter, the calculation of specific instances, and a graph showing surface areas per gallon with decreasing droplet diameter. Two photographs showing the attack on a fiercely burning fire and its extinction in 50 sec. with a spray supplied by an ordinary orchard sprayer are reproduced.

## AGRICULTURAL ECONOMICS

**[Papers and notes on agricultural economics]** (*Jour. Farm Econ.*, 24 (1942), No. 4, pp. 743-895, figs. 6).—Papers are included on: Bases for Controlling Agricultural Prices, by G. Shepherd (pp. 743-760) (Iowa Expt. Sta.) ; Agricultural

Income and the Export Market, 1910-1940, by M. Clawson and J. D. Black (pp. 761-771); Wartime Wheat Policy in Canada, by H. S. Patton (pp. 772-791) (Mich. State. Col.); Cross-Sectional and Case-Grouping Procedures in Research Analysis, by L. A. Salter, Jr. (pp. 792-805) (Univ. Wis.); Effects of American-Canadian Trade Reciprocity on Agriculture, by R. L. Mighell (pp. 806-821) (U. S. D. A.), with a discussion by R. H. Allen and D. L. MacFarlane (pp. 822-825) (Univ. Ky.); Hired Farm Labor in World War II, by H. Schwartz (pp. 826-844); Control of Consumption in Britain, by B. Brandis (pp. 845-856); Trends in Agricultural Cooperation, by E. A. Stokdyk (pp. 857-865); and Emergency Control in the Farm Real Estate Market, by M. M. Regan and F. A. Clarenbach (pp. 866-882) (U. S. D. A.).

Notes are included on: Regulating Output via Multiple Prices, by S. Enke (pp. 883-889) (Univ. Calif.); Comment on "The Scale of Operations in Agriculture," by W. L. Cavert (pp. 889-890) (U. S. D. A.) (E. S. R., 88, p. 393); Rejoinder to Comments by Cavert, by R. W. Rudd and D. L. MacFarlane (p. 891) (Univ. Ky.); and Some Limitations to Use of Coefficients of Variation, by J. J. Livers (pp. 892-895) (Mont. State Col.).

[Investigations in agricultural economics at the Georgia Station, 1942]. (Partly coop. U. S. D. A.). (*Georgia Sta. Rpt. 1942*, pp. 7-12).—In addition to findings and investigations previously noted, brief findings of a general nature are reported for a farm organization and enterprise study in Bulloch County and a study of cotton marketing.

[Investigations in agricultural economics by the Kansas Station, 1941-42] (*Kansas Sta. Bcn. Rpt. 1941-42*, pp. 10-14).—Brief reports are included on studies by W. E. Grimes, J. A. Hodges, W. H. Pine, R. J. Doll, H. J. Meenen, M. L. Otto, H. E. Myers, H. Howe, G. Montgomery, P. Wilson, R. W. Hoecker, and S. W. Decker as to factors affecting the organization and operation of Kansas farms; the development of an agricultural land-use program for the State (coop. U. S. D. A. and Kans. State Col.); land tenure and related problems; the marketing of grain, livestock and livestock products, and fruits and vegetables; and the economics of the poultry industry.

[Investigations in agricultural economics by the North Dakota Station] (*North Dakota Sta. Bimo. Bul.*, 5 (1942), No. 2, pp. 28-32, 49-50).—Included is an article, Co-operatives Require Knowledge and Understanding, by J. P. Greenlaw, F. B. Daniel, and R. F. Novak (pp. 28-32). It is based on a study of cooperative elevators in all but six counties of North Dakota. The chief objective of the study was "to ascertain group relationship practices and, so far as possible, to determine the relationship between certain practices in the field of group relationships and the success of cooperatives as businesses and as social institutions." The tables of average prices received by North Dakota farmers and the indices of North Dakota agriculture are brought down through October 1942 by P. V. Hemphill (pp. 49-50).

Current Farm Economics, [December 1942] (*Oklahoma Sta., Cur. Farm Econ.*, 15 (1942), No. 6, pp. 173-196, figs. 2).—In addition to the usual review of the agricultural situation and tables on prices, price indexes, and indexes of purchasing power of Oklahoma products, etc., articles are included on Labor Skill Requirements Vary With Types of Farming, by P. Nelson and A. B. Eden (pp. 185-188), and Simple Conservation Practices Are Weapons of War, by E. A. Tucker (pp. 189-182).

Statistical comparisons of record-keeping farms and a random sample of Iowa farms for 1939, J. A. HOPKINS. (Coop. U. S. D. A. et al.). (*Iowa Sta. Res. Bul. 308* (1942), pp. 265-287, figs. 7).—When the results were compared for 1939, the net income per 100 acres varied significantly between the two groups

of farms, with the record-keeping farms well above the random sample. An extra acre on the record-keeping farms added \$9.18 to net income, but on the random-sample farms only \$5.01.

**Twenty-one years of Iowa farm records, J. A. HOPKINS** (*Iowa Sta. Res. Bul. 309* (1942), pp. 289-352, figs. 29).—A summary of over 11,000 records kept by Iowa farmers from 1920 to 1940 showed that the record-keeping farmers' gross sales were from 140 to 190 percent above those of the average Iowa farm. The gross income recovered rapidly after the 1921 post-war depression, rising from \$1,700 per 100 acres to \$3,000, a level which was held from 1925 to 1929, declined to about \$800 in 1932, and then recovered to \$2,800 in 1940. Net income followed the same general course. Expenses followed a course similar to gross income, but operating expenses declined only about one-half as much as receipts and tended to lag somewhat behind receipts. Fixed expenses declined from about \$500 per 100 acres in 1920 to \$400 in 1929, then to \$280 in 1933, and rose but little between 1933 and 1940. The value of land and improvements declined from about \$24,000 per 100 acres in 1920 to about \$9,000 in 1933. By 1940 these two types of assets were practically back to their 1920 levels.

**Cropper farming in the Coastal Plain, G. W. FORSTER** (*North Carolina Sta. Tech. Bul. 73* (1942), pp. 58, figs. 10).—Data collected on 110 farms between 1928 and 1937 indicated that the average cropper-operated farm studied had approximately 88 percent of its total resources invested in land and 12 percent in livestock, machinery, feed, and supplies. Less than 10 percent of cropland was planted to soil-improving crops. Livestock was largely work stock. About 70 percent of the cropland was devoted to cotton and tobacco. The cropper unit averaged 23.6 acres in 1928, varying from 19 to 48 acres, and the average income per cropper unit was less than \$1,000. The average gross cash income per unit ranged from \$1,034 in 1928 to \$663 in 1940. Net cash income varied from \$770 in 1928 to \$522 in 1940. More livestock and soil-conserving and soil-improving crops are recommended. A reorganized farm, on which the soil was protected and utilized more effectively, indicated an increase in the net income over the usual of approximately \$1,453.

**Economic problems of low income farmers in Iowa, L. W. WITT.** (Coop. U. S. D. A. et al.). (*Iowa Sta. Res. Bul. 307* (1942), pp. 205-263).—Among other things, it was found that Farm Security Administration clients operated farms somewhat larger than those of other low-income operators with less current assets in the northeastern dairy and eastern livestock areas and more current assets in the central cash grain and western livestock areas of the State. In all areas, the F. S. A. clients operated their farms more efficiently than did the other low-income operators. The F. S. A. operators had a high volume of business and a low level of operating expenses.

**1943 production intentions, Rhode Island, A. L. OWENS** (*Rhode Island Sta. Misc. Pub. 14* (1942), pp. [1]+12).—This preliminary report is based on the analysis of 890 answers in questionnaires distributed to farmers. In the analysis, the farms are grouped by counties and by principal sources of income—dairy, poultry, vegetables, potatoes, and miscellaneous. The estimated 1943 production prospects are expressed in percentages of those for 1942.

**Livestock transportation and processing problems in 1942-43 and 1943-44, K. BJORKA, C. L. HARLAN, and F. L. THOMSEN** (*U. S. Dept. Agr., Bur. Agr. Econ., 1942, pp. [2]+30, figs. 4*).—The problems are discussed under the following headings: Prospective marketings of livestock, transportation facilities in relation to marketings, hog slaughtering capacity in relation to marketings, possible bottlenecks and difficulties, and alternative methods of meeting a possible emergency.

**The marketing of Washington apples in Los Angeles, California.—III, Consumer use and preference, M. T. BUCHANAN** (*Washington Sta. Bul.* 423 (1942), pp. 32, figs. 4).—In continuation of these studies (E. S. R., 88, p. 268), it was found that the average monthly consumption of apples per family was 13.9 lb. and the average monthly consumption per person was 4.4 lb. Of the total apples used by the 207 Los Angeles families interviewed, 62 percent were consumed raw, 16 percent were made into applesauce, 11 percent baked, 8 percent used in the preparation of apple pies, and 3 percent used in other ways. Delicious apples comprised 43 percent of all apples consumed without preparation. Next in importance was Jonathan. Consumers were more familiar with varieties used for raw consumption than with those used for cooking and the like.

**Statistics on receipts and distribution of sugar in the United States, 1934–39** (*U. S. Dept. Agr., Statis. Bul.* 77 (1942), pp. VII+69).—"In 1934, with the passage of the Jones-Costigan Act, the principal features of which were continued in the Sugar Act of 1937, the Federal Government undertook to exercise comprehensive regulation of the sugar industry. This control included a division of the United States sugar market among the various domestic and foreign areas that supply it; provided for regulation of sugar imports and receipts from offshore areas; and authorized control of distribution of returns among growers, processors, and laborers through a tax-payment program. . . The data published in this report make available for permanent record the current statistics issued periodically by the Department since 1934 in connection with the operation of the sugar legislation, and, in addition, considerable data not heretofore published. Included in the latter are receipts of offshore sugar according to polarization groups and by ports of entry."

The tables are grouped into three sections, as follows: (1) Continental United States deliveries, stocks, receipts, meltings, and production of cane and beet sugar for consumption and export, 1935–39, inclusive; (2) charges against United States sugar quotas for domestic and foreign areas, 1934–39, inclusive; and (3) continental United States receipts of raw, direct-consumption, and liquid sugar, 1938 and 1939.

**A study of consumer demand for eggs and poultry in the resort areas of western Michigan, H. P. GASTON** (*Michigan Sta. Quart. Bul.*, 25 (1942), No. 2, pp. 162–175, figs. 4).—The principal objectives of the study were "to examine and measure the seasonal variations in demands for eggs and poultry, and to determine the sources of supply." Data were obtained from the managers of representative retail stores, restaurants, hotels, resorts, and poultry dealers located in counties bordering on Lake Michigan. The egg section of 117 and the poultry section of 92 questionnaires, filled in at the time of the interviews, formed the basis of the present report. The seasonal variations in demand for eggs; the sources of supply; the channels of trade; grades of eggs demanded by retailers, hotels, restaurants, and resorts; and storage, etc., of eggs are described. For chickens, the seasonal variation in the demand, sources of supply, channels of trade, types demanded, and the difficulties of procuring suitable and adequate supplies are discussed. Turkeys are considered briefly.

The grades and types of eggs and poultry demanded by the Jewish element, who compose an important part of the resort population, have a marked influence on the production and marketing practices of the area. During the resort season the demand for eggs is over 300 percent and for chickens more than 370 percent of the normal or winter-season demand. Most of the eggs and chickens were produced locally. Hotels and restaurants stored 78 percent of the eggs used under refrigeration. Retailers kept only 21 percent under like

conditions. During the resort season the average hotel and restaurant held eggs 3.4 days before using. The average retailer held them for 3.6 days. More than 50 percent of the chickens used during the resort season were broilers, while only 8 percent of the fowls handled by retailers and 2 percent of those handled by hotels and restaurants were turkeys.

**Fluid milk consumption increases with income** (*Pennsylvania Sta. Bul.* 429 (1942), pp. 29-30).—A table is included, by C. W. Pierce, showing by the years 1936-41 the population in Allegheny County using purchased milk, the daily sales of fluid milk and fluid cream, and the daily consumption per capita of milk, cream in milk equivalent, and total milk equivalent.

**Factors affecting butterfat prices in Kansas**, G. MONTGOMERY and F. L. PARSONS (*Kansas Sta. Bul.* 309 (1942), pp. 28, figs. 12).—The trends in butter production, butterfat production in Kansas, the methods of selling butterfat, the establishment of butterfat prices, the seasonal trend of the prices, the causes for the fluctuations in prices, the demand for butter, and the monthly average price at Kansas City are analyzed and discussed.

There is a large variation from creamery to creamery in the general price level of butterfat in Kansas, but where collection is made through local cream stations the price tends to be equal to  $1\frac{1}{4}$  times the Chicago prices of 90-score butter in Chicago less collection, manufacturing, and shipping costs of 8 to 10 ct. per pound. Prices paid for direct shipments of butterfat tended to average about 2 ct. per pound more than the prices paid by local stations. Efficiently operated cooperative creameries paid from 5 to 7 ct. per pound above local station prices.

**[The rise of retail food prices in Puerto Rico]**, S. L. DESCARTES (*Puerto Rico Univ. Sta. Mimeog. Rpt.* 20, Sups. 3 [1942], pp. 14; 4, pp. 15; 5, pp. 16; 6, pp. 15; 7, pp. 6).—These supplements (U. S. R., 87, p. 293) are in Spanish and English. The index number of retail costs of all foods in Puerto Rico rose from 142 on February 17, 1942, to 150 on March 17, 159 on April 14, 170 on May 12, 172 on June 15, and 174 on July 14. The imported foods rose from 161 to 174, 181, 201, 204, and 205, while the locally produced foods rose from 121 to 125, 137, 141, 142, and 144.

**Foreign Agriculture, [December 1942]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 6 (1942), No. 12, pp. 385-408, figs. 2).—Included are articles on Bolivian Progress Toward Expanded Agricultural Production (pp. 387-395) and Argentine Grape and Wine Control Program (pp. 396-408), both by L. C. Nolan.

## RURAL SOCIOLOGY

**Field research and the concept of assimilation**, N. L. WHETTEN and A. W. GREEN. (Univ. Conn.). (*Rural Sociol.*, 7 (1942), No. 3, pp. 252-260; *Span. abs.*, p. 252).—This paper reports the testing of the assimilation concept in a study dealing with ethnic group relations in a rural area of Connecticut. So many qualifying factors must be taken into account to measure assimilation that the concept becomes too unprecise to be of value in scientific research. A few of these factors are: The class structure, rural-urban differences, and the heterogeneity of cultural values. Diversification is so great along some of these lines that it is impossible to recognize "assimilation" in the field.

**Size as a factor in population changes of incorporated hamlets and villages, 1930-1940**, S. C. RATCLIFFE (*Rural Sociol.*, 7 (1942), No. 3, pp. 318-328; *Span. abs.*, p. 318).—Hamlets and villages are divided into four classes and the percentages which lost population computed. Causes of population changes are discussed; a review of the changes for five decades is presented; and a possible future development is stated.

**Population rises less rapidly as State ages** (*Pennsylvania Sta. Bul.* 429 (1942), p. 31).—It is shown by H. R. Cottam that the rate of population increase in the State is slowing down. For the first time, between 1930 and 1940 the rural population grew at a faster rate than the urban. The average age is rising.

**Agrarian conflicts in New York and the American Revolution**, I. MARK (*Rural Sociol.*, 7 (1942), No. 3, pp. 275-293; *Span. abs.*, pp. 275-276).—Feudal forms in colonial New York existed, though they were not as profound in influence as were phases of the land system not strictly feudal. Thus an oppressive economic dependence was reflected in small farmer obligations and insecure tenure. Furthermore, the concentration of land ownership nurtured a landed aristocracy who flourished in a congenial legal and political milieu in which monopoly of land and office was securely maintained. Of these possible seeds of agrarian unrest, only the nonfeudal ones sprouted into violence in colonial New York. The Revolution had undeniable effects upon the land system, particularly in sweeping away lingering feudal forms though not the continuing oppression of the small farmer.

**Changes in rural life growing out of the war**, B. RYAN and C. A. ANDERSON. (*Iowa Expt. Sta.*). (*Rural Sociol.*, 7 (1942), No. 3, pp. 239-252; *Span. abs.*, p. 239).—Effects of the war upon four aspects of rural life are presented—population trends and migration, urbanization of rural culture, community organization, and the role of agriculture among the great groups within the Nation. War will depress rural fertility by virtue of mobilization, urban migration, and urbanization of family attitudes. Migration will be more diffused than in 1917-18 and greater in volume. The prospects for post-war industrial conversion are favorable enough to anticipate a limited back-to-the-land movement. The rural community will temporarily be more integrated, but the total effect of the war will be to increase secularization. Some resurgence of nativistic nationalism, particularly in rural areas, may be anticipated. Farmers as a national pressure group will find their recent favored status and subsidies threatened after the war. New welfare policies will probably favor the disadvantaged groups of farmers rather than commercialized farmers.

**Culture change in southern Illinois**, H. PASSIN (*Rural Sociol.*, 7 (1942), No. 3, pp. 303-317; *Span. abs.*, p. 303).—This article deals with the process of culture change in Stringtown from a "neighborhood" to a "town-country" stage, with particular reference to the relations between economic changes and other cultural changes in the community.

**A study of factors affecting the social well-being of rural people in Kansas**, R. C. HILL. (Coop. U. S. D. A.). (*Kansas Sta. Bien. Rpt.* 1941-42, pp. 14-15).—The results indicate a decline in farm population, a decrease in the number of births and in the number of deaths, a decline in movement from farm to farm, and an increase in the migration from farms to cities in 1941.

**How satisfying is rural life?** L. NELSON and E. McVoy. (Minn. Expt. Sta. coop. U. S. D. A.). (*Rural Sociol.*, 7 (1942), No. 3, pp. 261-267; *Span. abs.*, p. 261).—This study reports an attempt to measure the relations of rural people to the kind of life they lead in Isanti County, Minn. The random sample included both farm and village women. The results indicate that degree of satisfaction with items of family living is related to economic status, place of residence (village or farm), nativity, age, education, family composition, social participation, and general social adjustments. Farm women showed higher dissatisfaction on all categories of family living than did the village women. Security was apparently the item of greatest dissatisfaction among village women, with clothing ranking first in the case of farm women. Lowest dis-

satisfaction score for both farm and village women was \_\_\_\_\_ after of social participation.

**The problem of rural housing in the South, T. G. STANDING.** (U. S. D. A.). (*Rural Sociol.*, 7 (1942), No. 3, pp. 267-275; *Span. abs.*, 268).—Programs for the improvement of rural housing should recognize geographic and cultural variations, but the structure of the dwelling should be determined primarily by the needs of the family. An effective program of rural housing improvement will require some form of public subsidy. With proper planning such a program might well help to lessen the shock of conversion to a peacetime economy following the war.

**Selected farmer attitudes, A. L. BERTRAND** (*Rural Sociol.*, 7 (1942), No. 3, pp. 294-303; *Span. abs.*, p. 294).—This is a study of farmer attitudes and attitude differentiation between agricultural planning community committeemen and noncommitteemen in Grant County, Ky. In attitude and opinion, the committee members exhibited a relatively consistent pattern of differentials from the general belief of their neighbors. Compared to noncommittee members, committee members have a more general belief that education makes young people better farmers; are more consistent in their suggestion that rural living levels have become somewhat higher and that rural satisfaction has increased during their generation; more often believe that the production of their farm has increased since the conservation program; express a more general belief that farmers did not have prior knowledge of conservation problems; and more frequently indicate an anticipation of permanent tenure. They are in more complete agreement that land use has changed for the better since the adoption of the Federal programs, and are relatively more favorable in the evaluation of the Agricultural Adjustment Administration.

**Social and ecological patterns in the farm leadership of four Iowa townships, B. RYAN.** (Coop. U. S. D. A.). (*Iowa Sta. Res. Bul.* 306 (1932), pp. 141-202, figs. 3).—The author found that traditional bases of confidence were reinforced by recognition of ability, while technical bases of trust were relegated to an advisory capacity. No evidence was found that the farmers studied would escape from a democratic conception of planning and action through reliance upon bureaucratic stimulation and direction.

**The rural youth of Ross County: Their level of living and social achievement, A. R. MANGUS and R. L. McNAMARA** (*Ohio Sta. Bul.* 635 (1942), pp. [1]+27, figs. 7).—This study, which included interviews with 1,602 rural youths 18 to 27 yr. of age, showed that wide differences in living standards are found among rural youths when divided into different advantage groups on the basis of certain facilities and conveniences in their homes. Advantaged male youth had from 1.1 to 1.9 times greater advantage of obtaining full-time employment. The most disadvantaged young women had married in larger proportions, and had borne nearly four times more children than the more advantaged married women. Attitudes of satisfaction, optimism, or enthusiasm among youths increased as their level of living increased.

**Will we help youth preserve democracy? R. W. ROSKELLEY, P. M. BERRY, and G. E. KLIPPLE.** (Coop. Colo. State Col. et al.). (*Colorado Sta. Bul.* 473 (1942), pp. 47, figs. 15).—This is an analysis of the problems of youth in two rural towns in Colorado, beginning in 1936, and dealing with personal characteristics, migration, employment, economic status, and participation in organizations and leisure-time activities. Some suggested projects for study are included.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**The earth and man: A human geography**, D. H. DAVIS (*New York: Macmillan Co., 1942, pp. XXIII+675, figs. 452*).—This textbook, designed for first-year classes in colleges and universities, contains data on many subjects pertaining to agriculture, such, among others, as soils; drainage; forests and forest industries; deforestation; grasslands and grazing; primitive, oriental, and occidental agriculture; climatic elements and classification; and weather prediction.

**Slidefilms of the U. S. Department of Agriculture** (*U. S. Dept. Agr., Misc. Pub. 506 [1942], pp. IV+24*).—A catalog and price list of the slidefilms of the Department. The films are listed alphabetically by topics.

## FOODS—HUMAN NUTRITION

[**Foods and nutrition at the Bureau of Home Economics**] (*U. S. Dept. Agr. Bur. Home Econ. Rpt., 1942, pp. 3-7*).—This annual report (E. S. R., 86, p. 700) summarizes the analytical and compilation work on the nutritive value of foods, investigations on the dehydration of foods, and other food-conservation measures.

[**Food and nutrition studies by the Georgia Station**]. (Partly coop. Miss., Okla., S. C., Tex., Va., and La. Expt. Stas.). (*Georgia Sta. Rpt. 1942, pp. 89-90, 91-92*).—This report indicates progress in the continuation of cooperative studies reported earlier (E. S. R., 86, p. 854) concerning the composition of southern-grown vegetables, with particular reference to the mineral content of cowpeas as affected by environmental conditions and the ascorbic acid content of turnip greens as affected by variety, environment, maturity, storage, and cooking. Brief note is also made of results obtained so far in a study of the comparative value of peanut and milk proteins in the diet of the rat. The utilization of peanuts or peanut butter in the human diet to improve its protein value and content of the vitamin B complex is suggested.

[**Research in foods and nutrition by the Cornell Station**] (*N. Y. State Col. Home Econ., Cornell Univ., Ann. Rpt., 16 (1941), pp. 29-31, 35-36*).—In addition to work noted from other sources, summaries are given for completed studies by A. M. Briant, under the direction of C. J. Personius, on some physical properties of potato starch and their relation to the culinary quality of potatoes; by A. Richetta, under the direction of Personius, on the effect of some physical and chemical properties of egg whites and of other factors on the quality of soft meringues; and by H. P. Leahy, under the direction of K. W. Harris, on dry-milk solids in institution recipes. Progress is also reported in continuance of the project on quality and economy in the selection of potatoes for the institution.

**Southern bread enriched with peanut flour** (*Food Mater. and Equip., 1 (1941), No. 4, p. 6, fig. 1; also in Bakers Digest, 16 (1942), No. 8, p. 161, fig. 1*).—Peanut flour for human consumption is noted as an additional product providing an outlet for the large quantity of peanut meal resulting from the expanded production of peanut oil. Comparative data on protein, mineral, and vitamin content of patent and whole-wheat flours, peanut flour, peanut and patent flour and peanut and whole-wheat flour mixtures, and enriched flour show the superiority of the peanut flour over the wheat flours in nutritional value. The data indicate that a peanut-patent flour blend (25:75 percent) needs no additional calcium, riboflavin, or niacin, and that substantially decreased amounts of thiamin and iron are sufficient to conform to the standard for enriched

flour. Formulas utilizing this flour blend are reported as having been used with considerable success by bakers in Albany, Ga.

**The use of rice polishings in cooking**, M. E. HOLLINGER (*Louisiana Sta. Bul.* 355 (1942), pp. 8).—The use of rice polishings in human foods is recommended as a natural and economical method of adding thiamin to the diet. Tested recipes are given, chiefly of baked goods.

**Food processing [studies by the Georgia Station]** (*Georgia Sta. Rpt.* 1942, pp. 83–85).—This annual report notes progress in the investigation planned with the cooperation of the Tennessee Valley Authority, the U. S. Department of Agriculture, and the British Food Ministry and concerns the preservation of peaches, strawberries, blackberries, and youngberries with sulfurous acid.

**[Meat preservation studies by the Bureau of Animal Industry]** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1942, pp. 6–7).—This annual report makes note of investigations that have been undertaken to develop methods for producing safe, palatable, and nutritious dehydrated beef and for successfully preserving meat by frozen storage.

**[Freezer-locker utilization in Pennsylvania]** (*Pennsylvania Sta. Bul.* 429 (1942), pp. 31–32, fig. 1).—A survey by W. R. Whitacre of this form of food storage widely used by townfolk, as well as farmers in the State, showed that the more nearly full a freezer-locker is kept the lower the carrying charge per pound of frozen food.

**The nutritive value of quick-frozen foods**, M. N. GRAHAM (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1942), No. 8, pp. 243–246, 254).—This brief review points to the great increase in production of frozen fruits and vegetables within the last few years, indicates briefly the main types of freezing methods, deals briefly with the packing and storing of such products, and summarizes findings reported concerning the retention of micro-organisms during storage and the effect of freezing and freezing storage on the vitamin value of the foods.

**Preparing fruits and vegetables for the frozen food locker**, J. D. WINTER. (Univ. Minn. et al.). (*Minn. Hort.*, 70 (1942), No. 6, pp. 103–105, figs. 3).—General rules are given for the preparation and packing of fruits and vegetables and their juices, together with particular instructions concerning cherries, peaches, plums, and various berries. For dry sugar and sirup packs, the proportion of fruit and sugar (or sirup) is tabulated for standard and medium sugar-saving packs, with indication of the amounts of honey or of extra-sweet corn sirup that may be substituted for a portion of the sugar.

**Physical and chemical composition of chickens and turkeys**, M. M. HARSHAW. (U. S. D. A.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 6, pp. 365–366).—The data tabulated were compiled from various sources.

**Bacteriological survey of canned salmon**, O. B. WILLIAMS and E. D. CLARK (*Food Res.*, 7 (1942), No. 3, pp. 178–185).—In the 20-yr. period since the last bacteriological survey of canned salmon a number of changes in packing procedure have been introduced, including the use of a mechanical vacuum in place of the steam exhaust. An examination was made, therefore, of present packs put up by a number of packers and canneries and considered fully representative of commercial canned salmon. The 111 cans of salmon, examined by procedures outlined, included Columbia River Chinook and Alaska salmon (pink, chum, red, and king) obtained from the open market and from warehouse stock. A general consideration of all results, cultural, pH, and organoleptic, led to the conclusion that all cans tested were bacteriologically sterile. It was inferred, therefore, that changes in the packing introduced no new spoilage hazard, and that

the present process is adequate to insure sterilization. Attention was called to the importance of multiple controls in cultural tests for absolute sterility.

**The comparative nutritional value of butter and oleomargarine**, F. C. BING ET AL. (*Jour. Amer. Med. Assoc.*, 119 (1942), No. 17, pp. 1425-1427).—In this report, authorized for publication by the Council on Foods and Nutrition of the American Medical Association, the evidence on possible differences in the nutritive value of butter and oleomargarine as now produced is reviewed from the standpoint of their energy value, value as a source of essential fatty acids and carriers of fat-soluble vitamins, effect on requirements of other nutrients, and probable value as sources of unidentified factors. On the basis of the evidence reviewed, literature references to which are given as footnotes, it is concluded "that at present there is no scientific evidence to show that the use of fortified oleomargarine in an average adult diet would lead to nutritional difficulties. A similar statement is probably justified in the case of growing children, but preliminary results from animal experiments indicate that more work is necessary before any specific conclusions can be made. Since the nutritional factors have not all been identified, and since butter contains numerous additional fatty acids of unknown nutritional significance, the consuming public has a right to demand that the practice of identifying oleomargarine and butter so that any one can differentiate between them should be continued."

**[Nutrition studies by the Kansas Station]** (*Kansas Sta. Bien. Rpt. 1941-42*, pp. 61-62).—This annual report (E. S. R., 85, p. 125) presents brief summaries of the following projects, some of which have been noted elsewhere: The vitamin content of food in relation to human nutrition, by B. L. Kunerth, P. Nutter, and B. D. Westerman; the effect upon the animal body of varying amounts of vitamins in the diet, by L. Ascham, Nutter, and M. T. Harman; and the nutritional status of college women, by M. S. Pittman, Kunerth, E. J. Meiller, D. Cederquist, Ascham, and M. Geddes.

**Nutrition of humans** (*Pennsylvania Sta. Bul.* 429 (1942), pp. 15-16).—This progress report (E. S. R., 87, p. 589) deals with an extension of studies by N. B. Guerrant and R. A. Dutcher on the influence of exercise on the vitamin requirement of the rat, by Guerrant on the storage of vitamin A in the liver of rats, and by the Ellen H. Richards Institute on education as a means of improving vitamin A intake.

**Rhode Island food habits**, B. M. KUSCHKE (*Rhode Island Sta. Misc. Pub.* 13 (1942), pp. [1]+12).—The findings are summarized of a survey of the food habits of the State as revealed in over 1,600 replies to a questionnaire presented to the members of various groups, chiefly women, such as the Red Cross, college home economics classes, Y. W. C. A. and community classes, Parent Teacher groups, and home demonstration units, and points needing emphasis in educational work among such groups are suggested.

As evaluated by the score card developed by the Extension Nutrition Committee of the American Home Economics Association, only 9 percent of the diets could be rated as fully adequate, about 25 percent as 90 percent adequate, and slightly more than 25 percent as 80 percent adequate. Diets scoring less than 80 percent adequate, comprising 41 percent of the total, were probably deficient in one or more of the food essentials. A few diets scored as low as 20 percent adequate. One of the contributing causes of the low scoring was a very limited use of milk and whole grain cereals. Data of value in helping with the food rationing program were obtained from the records of food purchasing habits.

**Significance of the essential fatty acids**, G. O. BUER. (Univ. Minn. et al.). (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 2, pp. 224-233, figs. 9).—This review is limited to research dealing directly with the physiological effect of

the essential fatty acids. The significance of the term essential fatty acids is discussed, and the purified acids which have been tested for their activity in curing the fatty acid deficiency syndrome are enumerated, with their positive or negative effects. The subject is discussed further under the headings fatty acid deficiency and its cure by known acids; the daily requirement of the rat and other species for linoleic acid; and other physiological relationships, including vitamin B<sub>6</sub> and essential fatty acids, egg white injury or biotin deficiency, riboflavin, carotene and vitamin A, and fat transport and utilization. In conclusion, the author emphasizes the significance of the increasing number of reported interrelationships between the unsaturated acids and other essentials. "Undoubtedly the unsaturated acids function primarily as essential building stones in cell structures and in the mobile lipides. It would not be surprising to find numerous ill effects on domestic livestock and man of the present trend toward high carbohydrate diets containing small amounts of high saturated fats." A list of 92 references is appended.

The comparative rates of absorption of egg oil and cod liver oil, R. REDER. (Okla. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 6, pp. 528-531, (1).)—The amount of oil absorbed from the gastrointestinal tract of fasted rats following the administration by stomach tube of approximately 1.5 cc. of egg oil (obtained by ether extraction of egg yolks) or cod-liver oil was determined by thorough washing out of the excised gastrointestinal tract and extraction of the fat from the washings with petroleum ether. The maximum amount of fat recoverable was determined by analysis of the contents of the gastrointestinal tract of rats sacrificed immediately after the administration of the oil, with correction for the mean amount of residual fat normally present in the gastrointestinal tract of rats at the end of a 48-hr. fast. The amount of fat recovered, i. e., not absorbed from the gastrointestinal tract, was determined after 2-, 4-, 6-, and 10-hr. absorption periods and calculated as percentage of the maximum amount recoverable; the difference represented the percentage absorbed. During the 2- and 4-hr. periods, the percentages of egg oil absorbed, 25.9 and 43.3, respectively, were slightly less than those of cod-liver oil, 30.7 and 48.7, respectively. Between the 4- and 6-hr. periods there occurred a lag in the absorption of cod-liver oil; at the end of 6 and 10 hr., respectively, only 58.8 and 87.2 percent of the cod-liver oil had been absorbed as compared with 69.6 and 97.7 percent, respectively, in the case of the egg oil. From these results it appeared that the egg oil was more readily absorbed than the cod-liver oil.

The structural specificity of choline and betaine in transmethylation, A. W. MOYER and V. DU VIGNEAUD. (Cornell Univ.). (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 373-382).—Earlier work indicated that the methyl groups of choline were biologically labile (*E. S. R.*, 87, p. 745). The present study to determine the relationship between the structure of choline and this behavior involved the testing of the methyl-donating ability of a systematically varied group of compounds structurally related to choline. The growth of young rats on the methionine-free homocystine-containing diet to which the compound in question was added was used as a criterion of this ability.

"Of the many compounds tested, only choline (and simple derivatives thereof such as lecithin and phosphorylcholine), betaine, and dimethylethylhydroxyethylammonium chloride were found to support growth under these conditions. The synthesis of  $\alpha,\alpha$ -dimethylcholine and of diethylmethyl- $\beta,\gamma$ -dihydroxypropylammonium chloride has been described. The results of the present investigation are discussed with reference to the behavior of choline and related compounds in their ability to prevent development of fatty livers and hemorrhagic kidneys in the rat and to prevent perosis and act as a growth essential in the chick."

**Effect of dietary choline, ethanolamine, serine, cystine, homocysteine, and guanidoacetic acid on the liver lipids of rats, D. STETTEN, JR., and G. F. GRAIL** (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 175-181).—"The quantity of liver lipide and its composition with respect to nitrogen, phosphorus, and choline have been investigated in rats on various levels of choline nutrition, and with addition to the diet of ethanolamine, serine, cystine, homocysteine, and guanidoacetic acid. The liver fat which results from dietary choline deficiency is poor in lecithin, whereas that which results from the feeding of cystine or homocysteine is abnormally rich in this phosphatide. Ethanolamine and serine, when fed, produce no great increase in liver lipide but bring about a rise in monoamino phosphatides of this organ. The feeding of guanidoacetic acid causes a marked fatty liver with a coincident striking decrease in the choline content of the liver lipide. A hypothesis is offered relating these latter findings to the well-known irreversible biological methylation of guanidoacetic acid."

**Effect on growth and calcium assimilation of citric acid—potassium citrate mixtures, C. S. LANFORD** (*Jour. Nutr.*, 23 (1942), No. 3, pp. 293-300).—These tests were designed to ascertain whether the earlier observed effect of orange juice in increasing the assimilation of calcium by rats on a wheat-milk diet (*E. S. R.*, 84, p. 275) was due to the citric acid and citrates contained. The animals were fed the same basal diet as in the previous experiment with orange juice, but a citric acid-potassium citrate supplement was fed in amounts to furnish about twice the amount of citric acid and citrates that had been provided by the 10 cc. of orange juice. Animals in the present tests showed increased growth rates and an increase in total calcium retention in comparison with response of the control animals, but, unlike the animals receiving orange juice in the earlier tests, failed to show any increase in the percentage of the dietary calcium retained in the body of the growing animal. "It thus appears that orange juice favors calcium assimilation in growth through some property in addition to its content of citric acid and citrates and its preponderance of base-forming elements."

**Studies of liberal citrus intakes, I, C. S. LANFORD** (*Jour. Nutr.*, 23 (1942), No. 4, pp. 409-416).—Twenty-five young adult subjects, 9 women and 16 men, participated in the experiment in which they each drank 1,800 cc. of freshly extracted grapefruit juice over a 10-hr. period, within which time their meals were kept low in citric acid. Total citric acid (free acid and salt forms) and pH were determined in the 24-hr. urine sample obtained in the period beginning with the fruit juice ingestion; similar determinations were made on the 24-hr. sample preceding the grapefruit juice ingestion, citric acid intake during that period including only that from the basal diet. The increase in citric acid excretion on the experimental day as compared with the control day was small, averaging about 2 percent of the "extra" citric acid ingested in the grapefruit juice, and indicating that the subjects utilized about 98 percent of the citric acid and citrates ingested in the very liberal intake of grapefruit juice. "Further evidences of a high tolerance toward citrus fruits were the absence of subjective symptoms and the finding in each case that consumption of grapefruit diminished the acidity of the 24-hr. urine sample." The pH of the urine was increased in all cases by the consumption of the grapefruit juice, the average increase being 0.06. Separate studies in which a large single dose of grapefruit juice was taken and urine collections were made at short intervals showed a similarly high percentage utilization of the citric acid and a rise in urinary pH at all times up to 22 hr. after ingestion of the juice.

**Synthesis of inositol in mice, D. W. WOOLLEY** (*Jour. Expt. Med.*, 75 (1942), No. 3, pp. 277-284).—Evidence is presented that mice are able to synthesize

inositol if pantothenic acid is present in the diet. Spontaneous cures of alopecia in mice have been traced to the presence in the intestinal tract of micro-organisms capable of synthesizing inositol. About 60 percent of the total inositol content of normal mice was found to be free.

**Amino acids in hemoglobin formation**, F. S. ROESCHT-ROBBINS (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 2, pp. 219-224, figs. 2).—This address discusses the results of tests to determine the influence of individual amino acids on hemoglobin production in dogs made anemic due to loss of blood. When added at the optimum level of 1 gm. per day to the basal salmon-bread ration for a 2-week period, proline, threonine, glutamic acid, cystine, aspartic acid, histidine, glycine, and phenylalanine produced an average hemoglobin output of 34, 29, 25, 25, 25, 24, 23, and 23 gm., respectively, as compared with the average hemoglobin output of 100 gm. obtained with liver; nine other individual amino acids tested produced average responses varying from 10 to 20 gm. These results indicated that the dog had supplied other amino acids to supplement the specific ones given, and suggested that the amino acids may have accelerated the flow of other amino acids in the direction of globin construction. The addition to a basal nonprotein ration of 35 gm. of casein digest for a 2-week period produced in dogs depleted of plasma protein and hemoglobin increases of about 12 gm. of the former and 21 gm. of the latter. While the casein digest exerted only a moderate influence on plasma protein and hemoglobin production in these dogs, the digest was extremely effective in promoting abundant new plasma protein formation in a dog depleted of plasma protein alone. Enzymatic digests of hemoglobin administered intravenously in anemic dogs caused no hemoglobin production during the injection period (2 weeks), possibly due to toxic effect, but considerable hemoglobin and plasma protein were produced in the after-period. An amino acid mixture, theoretically furnishing all the nitrogenous essentials, was administered to a doubly depleted and nitrogen-starved dog. The amino acid mixture had no influence on either hemoglobin or plasma protein production, possibly because of utilization to satisfy more urgent needs or possibly because supplements which the body must contribute were not available in the severely depleted dog.

**The toxicity of fluorine in dicalcium phosphate**, F. DEEDS. (U. S. D. A.). (*Amer. Jour. Med. Sci.*, 203 (1942), No. 5, pp. 687-692).—Using the bleaching of rat incisor teeth as a criterion of injurious action, the fluorine present in dicalcium phosphate was shown to be as physiologically active as fluorine administered as sodium fluoride. The average daily dose of 1 teaspoonful of dicalcium phosphate containing 0.27 percent of fluorine represented a fluorine intake 10 times as great as the amount said to produce mottled enamel in at least some children.

**Human milk technology**, C. A. SMITH (*Jour. Ped.*, 20 (1942), No. 5, pp. 616-626, fig. 1).—This paper is concerned primarily with (1) methods of identification and tests for adulteration of human milk, (2) pasteurization and tests of pasteurization, (3) methods of preservation, and (4) the effect of some of these procedures on the food and vitamin values of the milk. The review is based on a rather scattered literature (32 references are cited) and on experience with certain procedures, including those for determining adulteration of human milk by the addition of cow's milk and those for preservation of milk. "In general, there is reason to conclude that the necessary process of pasteurization lowers the amount of vitamin C in human milk just as in cow's milk but does not otherwise alter its nutritional value, while the useful preservation process of slow freezing may also diminish the content of vitamin A. Whether this is sufficiently

depressed to require a vitamin A supplement (as well as one for vitamins C and D) might well be investigated."

**Some new dietary essentials required by guinea pigs**, D. W. WOOLLEY (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 679-684).—Two new factors, one soluble and one insoluble in 50 percent alcohol, were shown by the author, with the technical assistance of A. G. C. White, to be necessary for the survival and growth of young guinea pigs, and some evidence was obtained that a third factor is necessary for growth for longer periods than a few weeks. The first two factors have been concentrated, the second to a point at which 5 mg. per day produced good growth. Linseed oil meal was used in the concentration of the first of these factors, and dried grass and an alcohol-insoluble liver extract, as well as linseed oil meal, contained the second factor.

**The biological action of the vitamins: A symposium**, edited by E. A. EVANS, JR. (Chicago: Univ. Chicago Press; London: Cambridge Univ. Press, [1942], pp. IX+227, figs. 134).—This volume, bringing together the material on vitamins presented at the Chicago session of the Symposium on the Respiratory Enzymes and the Biological Action of Vitamins, September 1941, presents the following papers: The Biological Action of the Vitamins, by C. A. Elvehjem (pp. 1-16) (Univ. Wis.); Cocarboxylase, by S. Ochoa (pp. 17-42); Vitamin B<sub>12</sub>—Clinical Aspects, by N. Jolliffe (pp. 43-53); Riboflavin, by P. György (pp. 54-72); Human Riboflavin Deficiency (Ariboflavinosis), by W. H. Sebrell (pp. 73-83); The Story of Pellagra and Its Treatment With Nicotinic Acid, by D. T. Smith (pp. 84-110); Pyridoxine, by S. Lepkovsky (pp. 111-119) (Univ. Calif.); Pantothenic Acid and the Microbiological Approach to the Study of Vitamins, by R. J. Williams (pp. 120-135); Pantothenic Acid in Human Nutrition, by E. S. Gordon (pp. 136-143) (Univ. Wis.); Biotin, by V. du Vigneaud (pp. 144-168); (Cornell Univ.); Choline, by W. H. Griffith (pp. 169-184); The Economy of Phosphorus in the Animal Organism, by F. C. McLean (pp. 185-201); Vitamin K, by D. W. MacCorquodale (pp. 202-210); and Vitamin K—Clinical Aspects, by H. P. Smith and E. D. Warner (pp. 211-227).

**Occurrence of vitamins in fungi**, C. C. CARPENTER and E. W. FRIEDLANDER (*Science*, 95 (1942), No. 2477, p. 625).—Riboflavin as well as thiamin was found to be produced by *Aspergillus niger* grown either in normal cultures or in those poisoned with mercuric salts or other poisons. Other species of the higher fungi also found to produce riboflavin and thiamin included the common market mushroom, *Agaricus campestris*; *Peziza badia*, a fleshy ascomycete; certain species of the *Glaucus* group of *Aspergillus*; certain species of *Penicillium*; and some of the *Fusaria*. It is considered probable that the production of thiamin and riboflavin is a normal function of the fungi.

**The proper use of vitamins in mixtures**, T. D. SPIES ET AL. (*Jour. Amer. Med. Assoc.*, 119 (1942), No. 12, pp. 948-949).—This report, authorized for publication by the Councils on Pharmacy and Chemistry and on Foods and Nutrition of the American Medical Association, summarizes the symptomatology of multiple vitamin deficiency and methods of therapy, discusses the reason for reconsideration of the earlier stand of the Council on Pharmacy and Chemistry against polyvalent vitamin mixtures (E. S. R., 74, p. 421), states the principles for the formulation of acceptable mixtures of vitamins for therapeutic purposes, and gives specifications for seven vitamin concentrates or mixtures which will be given consideration by the council. In each case the material must include the specific vitamins in proportions related to the minimum daily requirements as defined by the U. S. Food and Drug Administration.

**Vitamin supplementation of U. S. Army rations in relation to fatigue and the ability to do muscular work, A. KEYS and A. F. HENSCHEL.** (Univ. Minn.). (*Jour. Nutr.*, 23 (1942), No. 3, pp. 259-269).—This is a condensed report of an investigation under rigidly controlled conditions of the physiological and biochemical responses to standard severe exercise, on a motor-driven treadmill, in 26 soldiers during four experimental series tests in which the subjects consumed the regular garrison ration, with varying supplements of the water-soluble vitamins as follows: Series 1, thiamin 5, nicotinamide 100, and ascorbic acid 100 mg. daily; series 2, thiamin 7, nicotinamide 100, calcium pantothenate 20, riboflavin 10, pyridoxin 10, and ascorbic acid 200 mg.; series 3, same as series 2, with an additional 10 mg. of thiamin; and series 4, 100 mg. of pyridoxin alone. The supplements were administered over periods of from 4 to 6 weeks, alternating with placebo administration. The general findings and conclusions are summarized as follows:

"In neither brief extreme exercise nor in prolonged severe exercise and semi-starvation were there indications of any effects, favorable or otherwise, of the vitamin supplementation on muscular ability, endurance, resistance to fatigue, or recovery from exertion. Healthy young men expending an average of 3,700 to 4,200 calories per day are not benefited by a daily supply of more than 1.7 mg. thiamin chloride, 2.4 mg. riboflavin, and 70 mg. of ascorbic acid. It is concluded that no useful purpose would be served by enrichment of present U. S. Army garrison rations with the vitamins studied."

**The chemical measurement and control of clinical vitamin deficiency, W. T. SALTER** (*New England Jour. Med.*, 226 (1942), Nos. 16, pp. 649-656; 17, pp. 688-694).—Following general considerations relating to the use of chemical measurements for detecting vitamin deficiencies, methods selected by the author and his associates as offering the best compromise between the various factors discussed are reviewed, with references to the literature for vitamin A, thiamin, riboflavin, niacin, and ascorbic acid. In a final discussion of the extent of vitamin deficiency in this country, it is pointed out that, although a biochemical method cannot answer the question as to how impoverished in vitamins a person must be before he is considered unhealthy, it can at least measure the degree of vitamin lack. "Already there is considerable evidence that in Minot's 'twilight zone' of subclinical vitamin lack, human efficiency and effectiveness may be greatly impaired. In the impending strain on national resources this approach will assume particular importance."

**The vitamins A and D potency of the oils obtained from the liver, intestines, body, and offal of shad (*Alosa sapidissima* Wilson) and mackerel (*Scomber scombrus* L.), L. I. PUGSLEY, J. T. KELLY, W. A. CRANDALL, and C. A. MORRELL** (*Canad. Jour. Res.*, 20 (1942), No. 6, Sect. D, pp. 167-169).—Data were obtained on the percentage of liver and intestines in the fish and on the percentage of oil in body, liver, intestines, and offal. The iodine value and percentage of unsaponifiable matter and the potency in vitamins A and D were determined in the several oils. Considerable variation in the vitamin potency was found for the individual samples, but the values for mackerel-liver oil were within the limits of those usually reported for halibut-liver oil, and the shad-liver oil approximated the potency of cod-liver oil. The body oil of both fish was devoid of vitamin A as shown by the antimony trichloride test. The intestinal oils of mackerel were relatively high in vitamin A but low in vitamin D.

**Comparison of vitamin A of liver biopsy specimens with plasma vitamin A in man, K. A. MEYER, H. POPPER, F. STEIGMANN, W. H. WALTERS, and S. ZEVIN** (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 589-591, fig. 1).—A com-

parison of the vitamin A content of the blood plasma by the Josephs modification (E. S. R., 83, p. 564) of the Carr-Price method with that of liver biopsy material determined by the same method after preliminary hydrolysis is reported for 34 patients requiring operations for various abdominal diseases. No parallelism was found between plasma and liver values, except that the concentration of vitamin A in the liver was never low in subjects with plasma values above 80 International Units per 100 cc. Plasma levels of 50 I. U. per 100 cc. were found in subjects whose liver vitamin A ranged from 40 to 612 I. U. per gram. Likewise, plasma levels as low as 10 I. U. per 100 cc. were found in subjects with liver concentrations up to 160 I. U. per gram. Apparently the vitamin A level of the blood fluctuates more readily and is sooner depleted than the vitamin A stores of the liver. The vitamin A distribution in the liver was also examined by fluorescent microscopy (E. S. R., 84, p. 558) and was found to agree fairly well with the content as determined chemically.

**The state of vitamin A in the liver of the rat. -II, The effect of feeding the vitamin over extended periods,** E. L. GRAY and J. D. CAWLEY (*Jour. Nutr.*, 23 (1942), No. 3, pp. 301-307, figs. 3).—In this continuation of the investigation noted previously (E. S. R., 84, p. 701), three groups of from four to six rats each were placed at weaning on the Sherman B diet supplemented with vitamin A in the form of cottonseed oil dilutions of dogfish-liver oil, dogfish-liver oil concentrate, shark-liver oil, and shark-liver oil concentrate furnishing 100 U. S. P. units of vitamin A per drop. The dosage was started at 1 drop daily, gradually increased to 5 drops daily, and continued through 112 days, at the end of which time the animals were killed and their livers subjected to similar analysis for vitamin A as in the first part of the investigation, including a final separation by molecular distillation. In contrast with the earlier study in which the vitamin, following the short-time feeding of large doses, was found to be in combination with several fatty acids, in the present study it was found to be combined with only one fatty acid, possibly palmitic. When the vitamin was fed for only 60 days, it was found combined with more than one fatty acid but not in as complex an ester combination as when the system was completely flooded with the vitamin. These findings are thought to indicate that the rat has a definite limit as regards its normal capacity for taking care of vitamin A.

**Vitamin A requirements in the rat. The relation of vitamin A intake to growth and to concentration of vitamin A in the blood plasma, liver, and retina,** J. M. LEWIS, O. BODANSKY, K. G. FALK, and G. McGUIRE (*Jour. Nutr.*, 23 (1942), No. 4, pp. 351-363, figs. 2).—This report embodies earlier data on the relation of vitamin A intake to blood levels and liver storage in the rat (E. S. R., 86, p. 562), with hitherto unpublished data on its relation to growth and the vitamin A concentration in the retina. Under the conditions of the experiment, daily feeding of 2 International Units of vitamin A represented the minimum for prevention of gross and histological evidence of vitamin A deficiency. On graded intakes of vitamin A, maximum growth occurred on 25 I. U., larger increases beyond this point resulting in no significant change. As vitamin A was not fed at levels between 10 and 25 I. U., the possibility is not excluded that some level between 10 and 25 I. U. might also have yielded maximum growth. Retinal concentrations of vitamin A reached their highest level at an intake of 2 I. U. daily. Combining these results with the earlier reported data for blood concentration and liver reserves, the requirement for optimal conditions with respect to various criteria in the young rat was in relative order—growth 25 I. U. daily, blood concentration 50, and good liver

reserves 100 I. U. daily. On a vitamin A-free diet, the plasma A concentration remained high in animals with large liver reserves and fell rapidly in those with low reserves, but the retinal concentration remained high even in the absence of the vitamin in the liver and its low concentration in the blood.

Attention is called to the similarity in these findings with earlier ones on infants in that the minimum requirement, as determined by dark adaptation, was found to be of the same order, 20 units per kilogram (E. S. R., 83, p. 849). For maximal blood concentration about 25 times as much vitamin A was found to be required as the minimum requirement for growth (E. S. R., 88, p. 282).

**The fate of excess vitamin A stores during depletion:** Value of the histologic demonstration of vitamin A, H. POPPER and S. BRENNER (*Jour. Nutr.*, 23 (1942), No. 5, pp. 431-443, pl. 1).—In this reinvestigation of the problem of vitamin A distribution and storage in the body, young rats given massive doses of vitamin A for nearly a month were examined periodically during a subsequent depletion period in groups of two males and two females each as follows:

The livers were examined for vitamin A histologically by the Popper method of fluorescent microscopy (E. S. R., 84, p. 558) and chemically by the method of McCoord and Luce-Clausen (E. S. R., 73, p. 274). The eyes were examined histologically and the pooled blood serums chemically.

The vitamin A fluorescence of the liver was found to run parallel with its vitamin A content at all levels, although the parallelism was more striking in the lower amounts. No simple parallelism appeared to exist between the vitamin A fluorescence of the liver and that of the retina or the vitamin A level of the blood. Under the opposite conditions of a superabundance of vitamin and advanced depletion, the Kupffer cells had a higher content of vitamin A than the liver cells, while in the intermediate stages representing probably the amount of A commonly found in adult stock animals (from 700 to 4,000 International Units), there was a homogeneous distribution of the vitamin A in the liver cells, with a fluorescence equal to or even greater than that of the Kupffer cells. It is thought that in hypervitaminosis the Kupffer cells store and then apparently destroy the excess of vitamin A, while in depletion the cells distribute the remnants of vitamin A. During depletion vitamin A was lost more rapidly from the livers of male than of female rats, but the histological picture showed no sex difference with respect to the method of utilization.

**The relation of liver stores to the occurrence of early signs of vitamin A deficiency in the white rat,** S. BRENNER, M. C. H. BROOKES, and L. J. ROBERTS (*Jour. Nutr.*, 23 (1942), No. 5, pp. 459-471, fig. 1).—In this phase of the general investigation, another phase of which is noted above, two series of tests were made. In the first, young rats were depleted of vitamin A from weaning and, in the second, after a preliminary period of administration of massive doses of the vitamin. The tests in both series included the appearance of early signs and symptoms of the deficiency in relation to the liver stores of vitamin A.

In the first series the small liver stores of vitamin A present at weaning were entirely lost by the end of the first week of depletion, but the blood and the eye tissues still contained appreciable amounts of the vitamin even after 7 weeks of depletion. Weight gains were slight, a microscopic examination of skin sections showed no abnormality, and macroscopic signs of vitamin A deficiency were mild. In the second series the liver storage at the beginning of the depletion period was high and showed no reduction during the first week of depletion. Thereafter the stores decreased rapidly until the eighth week, when the losses amounted to 93 percent. After this the loss was more gradual, the liver

still containing some of the vitamin at the thirtieth week of depletion. Blood levels of vitamin A decreased rapidly at first and then more gradually until a plateau was reached at about the thirtieth week. The vitamin A content of the retina decreased to the eighth week, when a plateau was reached. Even after the liver stores had been absent for several weeks, vitamin A was still present in the blood and the retinal tissues in amounts similar to that of stock rats at weaning age. Sex differences were found throughout. On equal intakes the males stored only two-thirds as much as the females per 100 gm., did not retain the vitamin as readily and had higher blood levels. These sex differences were found to be significant by Fisher's t-test.

**Dark adaptation of children in relation to dietary levels of vitamin A,** H. OLDHAM, L. J. ROBERTS, K. MACLENNAN, and F. W. SCHLUTZ (*Jour. Ped.*, 20 (1942), No. 6, pp. 740-752, figs. 3).—This further contribution to the question of the validity of the dark adaptation test and its reliability in diagnosing vitamin A subnutrition extends studies of Steininger and Roberts (*E. S. R.*, 83, p. 848) to the use of the Hecht adaptometer. "It reports the correlation of adaptometer readings and dietary studies, the effect of vitamin A supplements on dark adaptation, and a comparison of adaptometer readings of groups of children from different socioeconomic levels."

The mean rod thresholds of three groups of children from low, medium, and high socioeconomic levels known to have had widely different vitamin A intakes were almost identical, with approximately the same percentage of the subjects in each group showing subnormal dark adaptation. There was no correlation between adaptometer readings and daily vitamin A intakes. In tests of 50 matched pairs of children selected because of their low vitamin A intakes for comparison of the effect of the administration to one of each pair of 25,000 International Units of vitamin A each school day for a period of 9 weeks, a slightly larger number of children had vitamin A labile thresholds at the end of 2 weeks' supplementation than originally had thresholds in the subnormal zone, but, in general, the same children were classed as deficient by both methods. A slight but significant improvement was found in the mean rod plateaus of the children receiving the supplements than of paired controls, the effect being most pronounced in individuals whose original rod thresholds were in the subnormal zone. Significant improvement in rod thresholds was found in only 11 experimental as against 6 control subjects. "The above findings indicate either that the adaptometer does not measure the first signs of a vitamin A deficiency or that such a deficiency is uncommon among children in this area."

**Vitamin B<sub>1</sub> in Indian foodstuffs (cereals, millets, and pulses),** A. MADHAVA RAO, K. RAMACHANDRAN, and Y. V. S. RAO (*Cur. Sci. [India]*, 11 (1942), No. 4, p. 149).—The thiamin content, as determined by the rapid thiochrome method of Murty and Rao,<sup>3</sup> is reported for a number of commonly used cereals, millets, and legumes purchased in Bangalore markets. The values obtained for cereals and millets checked well with similar values obtained by the Pyke method (*E. S. R.*, 85, p. 701). In the case of legumes, values by the latter procedure were appreciably higher than those obtained by the rapid method.

**Vitamin B<sub>1</sub> and endurance,** P. V. KARPOVICH and N. MILLMAN (*New England Jour. Med.*, 226 (1942), No. 22, pp. 881-882).—Time tests of college men for horizontal arm-holding and for breath-holding proved unreliable as a means of detecting vitamin B<sub>1</sub> deficiency.

<sup>3</sup> *Cur. Sci. [India]*, 10 (1941), No. 3, pp. 180-182.

**Further studies on the urinary excretion of thiamin in children, R. A. BENSON, L. B. SLOBODY, C. M. WITZBERGER, and L. LEWIS** (*Jour. Ped.*, 20 (1942), No. 4, pp. 454-465).—The thiamin excretions of 75 children in acute, chronic, and convalescent stages of illness were studied in comparison with the previously reported study of 22 normal children (*E. S. R.*, 86, p. 868), and 55 of the children were also given test doses in an attempt to find a serviceable saturation test.

In the early convalescent stages of pneumonia the thiamin excretions of 12 subjects amounted to not more than 10 percent of the intake. In late convalescence 3 of 10 subjects excreted 20 percent and the others 15 percent or less of the intake. In 20 with rheumatic heart disease the inactive cases excreted over 20 and the active less than 20 percent, although a number of the latter group excreted more than 100  $\mu$ g. daily. Three children with common colds excreted more than 25 percent of the intake, while 5 with severe upper respiratory infections and 1 with acute bronchitis excreted 15 percent or less. In all other acute and early convalescent conditions the excretions amounted to less than 20 percent of the intake. Among the children with chronic conditions there were wide variations in outputs, both absolute and in percentage of intake. A low thiamin intake was the rule during the febrile phase of acute illness and a fairly low intake during early and late convalescence. Increased metabolism resulted in lowered thiamin excretion. Sulfathiazole treatment was found to have no significant effect.

Variable and inconsistent results were obtained in saturation tests given with both large and small test doses. The percentage of the dietary intake excreted was found to be a better indication of the degree of tissue saturation, with an average of 3 days preferred to a single determination. Thiamin supplements are recommended for children on an adequate diet (45  $\mu$ g. of thiamin per 100 calories) who habitually excrete less than 20 percent of their thiamin intake and (for short periods) for children convalescing from acute illnesses or suffering from chronic illness.

**Induced thiamine (vitamin B<sub>1</sub>) deficiency and the thiamine requirement of man: Further observations, R. D. WILLIAMS, H. L. MASON, B. F. SMITH, and R. M. WILDER** (*Arch. Int. Med.*, 69 (1942), No. 5, pp. 721-738, figs. 2).—Essentially noted from a preliminary report (*E. S. R.*, 88, p. 138).

**Why enriched bread?** R. R. WILLIAMS and R. M. WILDER (*Jour. Amer. Dietet. Assoc.*, 18 (1942), No. 4, pp. 225-229).—Wheat, it is pointed out, is the most important source of thiamin among foods consumed in amounts large enough to be significant in meeting the vitamin B<sub>1</sub> deficiency of the American diet. Due to popular resistance to whole-wheat bread, enrichment of white bread seems to be the logical way to introduce the needed thiamin into the diets of the greatest number of people. Statements by 21 leading teachers of medicine endorsing enriched white bread and flour are presented.

**Fluorimetric assay of riboflavin in the urine and tissues of rats, M. SWAMINATHAN** (*Indian Jour. Med. Res.*, 30 (1942), No. 1, pp. 45-52).—Balance experiments employing the methods noted on page 591 for the determination of riboflavin in urine and tissues were carried out for a period of 8 weeks on four groups of rats. The first two groups were fed a riboflavin-deficient basal diet supplying about 0.9  $\mu$ g. of riboflavin per rat per day, while the last two groups were fed a poor rice diet supplying about 2.2  $\mu$ g. of riboflavin daily per animal. In addition, each animal in one group on both the basal and the deficient diets received 50  $\mu$ g. of riboflavin daily mixed with the diet. In the groups fed the unsupplemented diet the daily excretion of riboflavin per rat was 1.9 to 2.6  $\mu$ g. respectively. The rats in both groups receiving the supplements excreted about

18  $\mu$ g., that is, about 45 percent of the ingested riboflavin. The riboflavin content of the liver, muscle, and heart of rats fed the unsupplemented diets was lower than that of the same tissues in rats receiving additional riboflavin and in stock animals.

**Investigations on the stability of avidin**, P. GYÖRGY, C. S. ROSE, and R. TOMARELLI (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 169-173).—The effect of various factors on the stability of avidin was studied. Solutions of purified avidin in concentrations of 1.0, 0.1, 0.01, and 0.001 mg. per cubic centimeter lost activity upon standing, the loss being more rapid in the dilute than in the concentrated solution. In any concentration the rate of destruction was much greater at 38° C. than at ice box temperature, and, except in the most concentrated solutions (0.1 and 1.0 mg. per cubic centimeter), even room temperature caused considerable acceleration of the rate. The loss of avidin activity in dilute egg white solutions was much less pronounced at these temperatures. Solutions of egg white or of purified avidin concentrate kept cooled under running water were irradiated with a 300-w. bulb at a distance of 12 cm. This irradiation inactivated the avidin in both solutions but more readily in solutions of the concentrates. In the latter, in very dilute solution (0.004 mg. per cubic centimeter), the irradiation even released the biotin bound to the avidin. The presence of riboflavin accelerated the action of the visible light. When solutions of egg white or of avidin concentrates were brought to pH 1.8 with HCl, their avidin activity was almost but not quite completely destroyed. Biotin already bound to the avidin was not released by the treatment with acid, nor was added biotin even when the avidin had been almost completely saturated with it.

**Yeast-growth-promoting effect of diaminocarboxylic acid derived from biotin**, V. DU VIGNEAUD, K. DITTMER, K. HOFMANN, and D. B. MELVILLE (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 2, pp. 374-375).—The diaminocarboxylic acid resulting from hydrolysis of the urea ring of biotin by the action of strong  $\text{Ba}(\text{OH})_2$  was found capable of stimulating the growth of yeast in a biotin-free medium. The compound possessed about 10 percent of the activity of biotin. Unlike biotin, it was not inhibited in its yeast-growth-promoting activity by the presence of purified avidin, thus suggesting that the urea ring is vital for the effect of avidin on biotin.

**Observations on the "egg white injury" in man and its cure with a biotin concentrate**, V. P. SYDENSTRICKER, S. A. SINGAL, A. P. BRIGGS, N. M. DEVAUGHN, and H. ISBELL (*Jour. Amer. Med. Assoc.*, 118 (1942), No. 14, pp. 1199-1200, fig. 1).—Three white men and one Negro woman in good condition and free from symptoms and signs of avitaminosis when the experiment began were maintained on a basal diet in which the vitamins of the B group were furnished in synthetic form and which contained desiccated egg white in amounts furnishing 30 percent of the total calories. The first signs of biotin deficiency appeared in all subjects during the third and fourth weeks in the form of a fine scaly, nonitching dermatitis, which disappeared spontaneously. The next indication of deficiency did not appear until the seventh week, when one of the subjects developed a maculosquamous dermatitis of the hands, arms, and legs. During this and the following week, all showed a grayish pallor of the skin, and the three white patients showed definite patches of atrophy of the lingual papillae. These did not develop in the Negro patient until the fourteenth week. During the ninth and tenth weeks the skin of the extremities was dry in all of the subjects and a dermatitis similar to that observed earlier developed in one case. After the fifth week, symptoms strikingly like those reported for thiamin deficiency appeared. Examination of the blood at intervals showed definite

decreases in hemoglobin, erythrocytes, and volume of packed red cells. The 24-hr. biotin excretion in the urine at the end of 7 and 8 weeks amounted to from 3.5 to 7.3  $\mu\text{g.}$  as compared with from 29 to 62  $\mu\text{g.}$  for subjects on a normal diet. These symptoms and signs were readily cured by the parenteral administration of a biotin concentrate. The doses administered varied from 75 to 300  $\mu\text{g.}$ , with 150  $\mu\text{g.}$  proving to be the minimal amount required for prompt relief of symptoms.

**The excretion of specific fluorescent substances in the urine in experimental nicotinic acid deficiency,** V. A. NAJJAR, H. J. STEIN, L. E. HOLT, JR., and C. V. KABLER (*Jour. Clin. Invest.*, 21 (1942), No. 3, pp. 263-267, figs. 5).—Two fluorescent substances designated as  $F_1$  and  $F_2$  were noted in human urine.  $F_1$ , with a whitish-blue fluorescence and maximum emission at 4,350 a. u., was present acute nicotinic acid deficiency was characterized by the disappearance of  $F_2$  with greenish-blue fluorescence (upon the addition of alkali) and maximum emission at 4,550 a. u., was present in appreciable amounts in normal urine but absent in pellagra. To study the excretion of these fluorescent substances in pure nicotinic acid deficiency, uncomplicated with other deficiencies as in human cases, four dogs on a blacktongue diet were employed. In these, as in the human beings, acute nicotinic acid deficiency was characterized by the disappearance of  $F_2$  excretion and a rise in  $F_1$  excretion. As the disease became chronic (after about 20 days) the excretion of  $F_1$  tended to fall. This trend also apparently occurred in human cases, since a much lower  $F_1$  excretion was observed in very severe human pellagra than in certain moderately severe cases. When nicotinic acid was administered to the dogs, the excretion of  $F_2$  increased while that of  $F_1$  decreased. The reciprocal relationship between the  $F_1$  and  $F_2$  excretions was not a perfect one, however, for upon withdrawal of the nicotinic acid therapy the fall in  $F_2$  excretion was not always accompanied by an equally prompt and impressive rise in  $F_1$ ; nor was the magnitude of the rise in  $F_2$  excretion always comparable to the degree of fall in the  $F_1$  excretion.

**Relationship between pantothenic acid requirement and age in the rat,** K. UNNA and G. V. RICHARDS (*Jour. Nutr.*, 23 (1942), No. 6, pp. 545-553, figs. 2).—The pantothenic acid requirement of rats at different ages was determined by feeding tests on graded doses. In weanling rats consuming an average of 5.3 gm. of the diet daily, the daily requirement for maximum growth and the prevention of the characteristic changes in the fur was approximately from 80 to 100  $\mu\text{g.}$ , while in rats 10 weeks or more of age, with an average food consumption of 15.5 gm. daily, the requirement was only 25  $\mu\text{g.}$  The time at which the sharp decline in requirements took place coincided with the period of decline in growth rate. In depleted rats a single curative dose was followed by a sustained gain in weight, with further doses producing a staircase effect. Attention is called to the striking difference between the response to thiamin and to pantothenic acid, the requirement of the former increasing and of the latter decreasing with age.

"The observation that the greatest need for pantothenic acid coincides with the period of maximal growth indicates that pantothenic acid may play a role in metabolism quite different from that of thiamin and other B vitamins connected with carbohydrate metabolism, and permits the speculation that it may be connected with metabolic processes involved in the formation of new tissue."

**Occurrence in natural products of a physiologically active metabolite of pyridoxine,** E. E. SNELL, B. M. GUIBARD, and R. J. WILLIAMS (*Jour. Biol. Chem.*, 148 (1942), No. 2, pp. 519-530).—A medium is described which, with the addition of pyridoxin, permitted luxuriant growth of *Streptococcus lactis* R but failed to support growth in the absence of pyridoxin or some tissue extract. This organism used with the basal medium in determining the pyridoxin content

of natural extracts gave values several hundred to several thousand times as great as could be accounted for on the basis of pyridoxin present. Preliminary fractionation experiments, not here described in full, showed the presence in these extracts of a substance responsible for the extra response. This substance, provisionally called pseudopyridoxin, was very similar to pyridoxin in its behavior toward adsorbents, eluting agents, acids, and bases, and in its migration in an electric field. Analyses of the tissues of normal and pyridoxin-deficient rats showed that the pseudopyridoxin content was greatly lowered in the latter tissues, while tissues of animals fed synthetic pyridoxin hydrochloride contained the pseudopyridoxin at levels often higher than those in normal animals. This distribution of pseudopyridoxin paralleled that of pyridoxin and frequently showed even greater differences in the same direction. The pseudopyridoxin content of the tissues paralleled the pyridoxin content of the ration and not the pseudopyridoxin content of the ration. The same was true for the concentrations in the urine as determined in excretion tests on rats. Following a test dose of pyridoxin, the excretion of pseudopyridoxin in human urine was greatly increased. "It is concluded that pyridoxin is converted by the animal organism to a metabolite of unknown nature which possesses much greater activity for *S. lactis* than does pyridoxin itself. This metabolite is generally distributed in natural products. The absorption of pyridoxin by *S. lactis* from media in which the pyridoxin concentration is the factor limiting growth does not occur to any appreciable extent in contrast to results secured with other vitamins under similar conditions. It is suggested that this result is the consequence of a necessary conversion of pyridoxin to pseudopyridoxin prior to utilization for growth by this organism."

**Physiological activity of ascorbic acid in plant life**, E. F. KOHMAN and D. R. PORTER (*Science*, 95 (1942), No. 2476, pp. 608-609).—Young tomato plants grown in pots and carefully washed free of soil contained from 46.3 to 62.8 mg. percent of ascorbic acid as analyzed in the evening. Comparable cut plants standing in water overnight gained in weight and contained from 22.5 to 47.7 mg. percent ascorbic acid, calculated back to the weight of the plants in the evening. These amounts of ascorbic acid in the cut plants were from 18 to 51 percent greater than the amounts in growing plants left standing overnight with water to cover the soil. These gained but little weight and contained from 18.2 to 31.5 mg. percent ascorbic acid. "The data indicate that the losses in ascorbic acid noted in vegetables and fruits in storage are not due entirely to oxidation by atmospheric oxygen, as is often stated, but due to its being used in some physiological process, the activity of which is diminished by severing the plant from the root system."

**Factors in processing which affect the ascorbic acid content of fruit and vegetables**, M. E. HUMMEL (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1942), No. 9, pp. 273-275).—This review, based on 44 studies which are cited, considers (1) losses associated with storage, dehydration, freezing, cooking, canning, and fermentation, and (2) retention of artificially added vitamins in the cooking of vegetables.

**Determination of vitamin C and its sampling variation in strawberries**, L. BURKHART and R. A. LINEBERRY. (N. C. Expt. Sta. and U. S. D. A.). (*Food Res.*, 7 (1942), No. 4, pp. 332-337).—Because of the des' uction of ascorbic acid occurring in the long period required to grind strawberries to a fine pulp with sand, a motor-driven, emulsifying blender was used in the present study in which a 25-gm. sample placed in the container with 75 cc. of a mixture of 4 percent metaphosphoric acid and 8 percent acetic acid was ground to a very fine pulp in 1 min. The extract was centrifuged for 15 min. and titrated immediately

with an electrometric titrimeter according to the method of Kirk and Tressler (E. S. R., 82, p. 730). Using this improved method of extraction, a study was made of conditions affecting methods of sampling. Considerable variation was found in the ascorbic acid content of commercially packed strawberries, five samples drawn at random from a single quart showing a range from 35.9 to 44.8 mg. per 100 gm. of fruit. In checking possible causes of such variation, it was found that the ascorbic acid content of sun-ripened berries was greater than that of berries ripened in the shade, and that similarly sampled berries from different fields varied appreciably in ascorbic acid content. This effect of soil variation was observed in Klondike strawberries from six fields, two experimental and four commercial, all receiving the same fertilizer treatment, the ascorbic acid content of the berries by fields ranging from 36 to 52 mg. per 100 gm. Close agreement was found between duplicate quarts sampled under the same conditions as to location, time, degree of maturity, exposure to sunshine, and size of fruit. With this careful attention to sampling, varietal differences were studied with Fairmore, Missionary, Massey, and Blakemore varieties which averaged, respectively, 66, 46, 42, and 33 mg. of ascorbic acid per 100 gm. The outer portion of the strawberry (representing about two-thirds of the fruit) was found to have a higher concentration of ascorbic acid than the center portion, being about 20 percent richer in the Blakemore variety and 9 percent richer in the Fairmore. In the Klondike strawberries the ascorbic acid content increased from 59 mg. per 100 berries (244 gm.) in the case of green berries to 280 mg. per 100 berries (605 gm.) in the ripe fruit, this representing an increase in concentration from 24 to 46 mg. per 100 gm.

**Vitamin C content of guavas**, W. W. BOYES and D. J. R. DE VILLIERS (*Farming in So. Africa*, 17 (1942), No. 194, pp. 319-336, figs. 7).—Ascorbic acid was determined by 2,6-dichlorophenolindophenol titration of a metaphosphoric acid extract of a composite sample of South African guavas freed of pips prior to extraction. Average, maximum, and minimum values for ascorbic acid content and for percentages of outer and inner flesh and pips are presented for the 5 types set up; values for ascorbic acid, ranging for all groups from 172 to 671 mg. per gram, were lowest for the varieties with salmon-colored flesh and increased in order for varieties with white, orange, pink, and deep pink flesh. The ascorbic acid content was generally lower in early-season guavas than in later-season types and did not always seem to be greatly dependent on maturity. The skin and outer flesh were the richest in the vitamin. Very little ascorbic acid was lost in stewing the guavas, and the canned product proved to be remarkably stable under adverse conditions. A concentrated guava extract, however, lost its ascorbic acid very rapidly, and dried guavas and guava powders, at first rich in ascorbic acid, lost potency very rapidly in the warm climate.

**Vitamin C in rose hips**, M. PYKE and R. MELVILLE (*Biochem. Jour.*, 36 (1942), No. 3-4, pp. 336-339).—A survey has been made of the vitamin C content of the ripe hips of a number of British roses and some foreign roses grown in England. "A number of common species contain large amounts of vitamin C, often exceeding 1 percent, in the flesh of the ripe hips. The species indigenous to Scotland and northern England appear to contain higher concentrations of vitamin C than those roses commonly found in the more southern parts of this island."

**Vitamin C in normal nutrition**, D. F. MILAM and W. WILKINS (*South. Med. and Surg.*, 104 (1942), No. 4, pp. [3]).—Data are reported on fasting plasma ascorbic acid levels at biweekly intervals during 6 weeks of 15 children on a low-cost adequate diet in a summer camp in North Carolina. The values at the beginning ranged from 0.2 to 1.1, with a mean of 0.52 mg. per 100 cc.; after 2 weeks

from 0.4 to 1.4, with a mean of 0.96 mg.; and after 4 weeks from 0.9 to 1.9, with a mean of 1.34 mg. per 100 cc. Two children were not included in the test at the end of the sixth week. The value for another who developed otitis media after the fourth week dropped from 1.9 to 0.5 mg. per 100 cc. Aside from this subject no one had values less than 1 mg. per 100 cc., and the mean, including the low value for the one subject, was 1.23 mg. per 100 cc. It is emphasized that in the dietary at this summer camp for children only low-cost foods were used, and that calculated at regular retail prices charged by the local grocery stores the diet could have been duplicated in the home at a raw-food cost of 21.6 ct. per child per day.

**Blood plasma ascorbic acid tests in mass studies in human nutrition,** J. M. SMITH, M. L. PRESPER, and A. M. MCCORMICK (*Pennsylvania Sta. Bul.* 432 (1942), pp. [3] + 55, figs. 35).—This bulletin covers two studies on the applicability of blood plasma ascorbic acid determinations by the Farmer and Abt micromethod (*E. S. R.*, 75, p. 588) to the evaluation of vitamin C status in mass studies in human nutrition and a comparison of the values obtained on 300 samples with the test as finally standardized with dietary intakes as secured from a 1-week record kept just before the test. The results obtained in the first two studies are indicated by the following recommendations.

"In making tests for vitamin C status on individuals in mass studies in human nutrition, it is recommended that each test be made between 3 and 3½ hr. after the last intake of food, as the last test in a half-day series of different nutritional tests on the same individual; that the samples be held in a refrigerator until a series of samples are taken from the different subjects participating in the mass studies during the half-day session; that no sample of blood plasma (nondeproteinized) be held longer than 30 min.; that analyses on deproteinized blood be completed within 2 hr. if possible; and that deproteinized serum never be held longer than 6 hr. before the analyses are completed."

In the comparison between plasma ascorbic acid and dietary intake of vitamin C, the coefficient of correlation (Pearson method) between one blood plasma ascorbic acid test and the corresponding dietary intake was  $0.51 \pm 0.03$ , indicating a high statistical relationship.

**Influence of hyperpyrexia on ascorbic acid concentration in the blood,** S. L. OSBORNE and C. J. FARMER (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 575-578).—Blood plasma ascorbic acid determinations were made on 17 chronic arthritis patients immediately before, during, and after a combination fever-cabinet and inductotherm-heat treatment, with temperatures maintained at 104°-104.6° F. (rectal) for 4 hr. The average of 77 determinations at each of the four intervals ranged from 0.62 to 0.68 mg. percent, the differences being statistically insignificant. This is thought to afford evidence that high body temperatures per se do not significantly increase the rate of utilization of vitamin C.

**The tocopherol (vitamin E) content of milling products from wheat, rye, and barley and the influence of bleaching,** C. ENGEL (*Ztschr. Vitaminforsch.*, 12 (1942), No. 3, pp. 220-222; *Gr., Fr. abs.*, p. 222).—The samples were extracted with peroxide-free ether, the extract washed with alkali, acid, and water and evaporated in vacuo, and the residue taken up in benzene. This solution was filtered over Floridin XS-earth to remove carotenoids, and the tocopherol content of the filtrate was estimated with ferrichloride-dipyridyl. The tocopherol content of various milling fractions of wheat and rye, as milled in the Netherlands, was determined by this procedure. The content varied with the degree of milling, increasing with increasing degree of extraction. Bleaching of the flour

with benzoyl peroxide and nitrogen trichloride caused considerable loss of tocopherol.

**Cure of repeated attacks of nutritional muscular dystrophy in the rabbit by alpha-tocopherol.** C. G. MACKENZIE (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 313-317, fig. 1).—Repeated attacks of muscular dystrophy, as judged by creatinuria, loss of weight, reduced food consumption, and physical symptoms, were induced in young rabbits on a dystrophy-producing diet. As many as six successive attacks were produced and cured each time by the administration of  $\alpha$ -tocopherol in amounts of from 5 to 15 mg. for the first three attacks and from 20 to 40 mg. for subsequent attacks. In contrast to animals permitted to succumb after the fourth or fifth attacks, the animals cured by from 2 to 4 weeks of treatment after the attacks showed, even after the sixth time, no hyalinization or necrosis or accumulations of cellular elements in the muscle tissue, and no testicular degeneration.

## TEXTILES AND CLOTHING

[Textiles and clothing at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt.*, 1942, pp. 7-9).—This annual report covering the progress of work in the Textiles and Clothing Division (*E. S. R.*, 86, p. 714) deals with clothes for women, cotton-stocking research, conservation of clothes and fabrics, and the use of substitute fibers.

**A. S. T. M. standards on textile materials.** H. J. BALL ET AL. (*Philadelphia: Amer. Soc. Testing Materials*, 1942, pp. XIII+408, figs. [76]).—This pamphlet, published annually (*E. S. R.*, 87, p. 156) and prepared by the A. S. T. M. Committee D-13 on textile materials, contains definitions and terms, methods of testing, and specifications for textile and related materials developed by the American Society for Testing Materials. "Additional material appearing in appendices as information include photomicrographs of textile fibers, tables on basic properties of textile fibers, for yarn number conversion, and relative humidity; proposed recommended practice for designation of yarn construction, glossary of textile terms, proposed recommended practice for calculating number of tests, drafts of new test methods, an American war standard for specification and description of color, and abstracts of papers presented at meetings of Committee D-13." The textile materials covered include those made from cotton, wool, rayon, silk, asbestos, bast leaf, and glass fibers. The 43 standards and 29 tentative standards "cover not only methods of test for textile materials but also tolerances within which the textile must come in order that it shall constitute a good delivery on contract. In addition to these test methods and tolerances, the committee has more recently undertaken the writing of specifications of textile materials for specific uses. These were prepared in response to a number of requests and cover such materials as tire cord, chafer tire fabrics, ducks, electrical tapes, asbestos textiles, household fabrics, etc."

**Determining the deterioration of cellulose caused by fungi: Improvements in methods.** G. A. GREATHOUSE, D. E. KLEMMER, and H. D. BARKER (*U. S. D. A.*). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 8, pp. 614-620, figs. 8).—The standardized quantitative method developed for the evaluation of the ability of fungi to decompose cellulose involved the use of replicate strips of the fabric incubated in individual chambers. These chambers were merely 16-oz. square bottles fitted with a modified cap in which glass cloth had been fitted to permit uniform aeration. Instead of solid mineral agar a liquid nutrient was employed, together with a width of glass fabric for the support of the test sample. A standard inoculum was introduced into the chamber and, after a

given incubation period, the average loss in breaking strength of the inoculated strips was determined and expressed as departure from the average of the controls. *McLarrhizium* sp. and *Chaetomium globosum* caused very rapid decomposition, were easily handled, and had other features that made them satisfactory test organisms. They were definitely superior to *C. clatum*, *Alternaria* sp., *Hormodendrum* sp., and *Stachybotrys papyrogena*. Ammonium nitrate was found to be a better source of nitrogen than sodium nitrate for the development of most of the fungi. The pH of the substrate appeared to have an important influence on the activity of cellulose-destroying fungi.

**Latest developments in milkweed floss**, L. STOFFER (*Rayon Textile Mo.*, 23 (1942), No. 10, pp. 55-56, figs. 2).—With the importation of kapok from Java cut off by the war, the commercial possibilities of the milkweed have found realization in the establishment at Petosky, Mich., of a small factory, backed by war orders, for the production of milkweed floss. Here the milkweed pods, from the wild crop of 50,000 acres in northern Michigan, are dried under gas burners, which causes them to crack open, liberating the floss. This is run through a milkweed gin which separates the seeds from the floss fibers. The milkweed floss, which has six times the buoyancy of cork and is lighter and warmer than wool, is admirably adapted for packing life jackets and lining aviators' jackets and flying suits. The seeds, which have an oil content of 20 percent, may be crushed to obtain this oil, which is valuable as a semidrying oil in paints. It is pointed out that in large processing operations the seed pods would be of value for the latex and wax (5 percent each), which could be extracted, and for the yield of fiber excellent for paper making. In addition, it is noted that the stalk yields three different fibers satisfactory for making paper, rayon, explosives, wallboard, plastics, or strong textiles such as those made from jute.

**The effect of resin finishes on the color fastness and physical properties of rayon gabardines**, H. M. FLETCHER, W. M. HAY, and A. J. SURREATT. (Kans. State Col.). (*Amer. Dycstuff Rptr.*, 31 (1942), No. 21, pp. 489-493, 514).—Viscose rayon gabardines, both resin- and non-resin-finished as determined by appropriate tests, were selected in light and dark shades of red, blue, green, and brown, for tests by procedures described, to determine the permanence of these finishes to dry cleaning and laundering and their effect on the colorfastness, breaking strength, elongation, and shrinkage. The resin-finished fabrics had a firmer handle than the non-resin-finished and had a better appearance after cleaning. Dry cleaning caused no loss in breaking strength, no change in elongation, and but little fading, and did not greatly affect the appearance in either group of fabrics. It did, however, cause shrinkage in both resin- and non-resin-treated fabrics, the former shrinking less than the latter by a highly significant amount. In the resin-finished fabrics there were no significant differences in the shrinkage for the dry cleanings and launderings, but for the non-resin-finished fabrics, the shrinkage due to laundering was significantly the greater. The shrinkage in the warp was significantly greater than in the filling for the resin-finished and highly significantly greater for the non-resin-finished.

Laundering caused greater fading than did dry cleaning, and the fading produced was significantly greater in the case of the non-resin-finished fabrics. Laundering decreased the breaking strength of the non-resin-finished but not the resin-finished fabrics, had no effect on elongation, and caused shrinkage of both fabrics, particularly those without finish, these becoming sleazy after laundering.

Statistical analysis of the data showed significant differences in the colorfastness and the physical properties favoring the resin-finished over the non-resin-finished fabrics. Thus the resin finish produced stronger gabardines as evidenced by increased wet breaking strength (but no increased resistance to abrasion) and

no decrease in breaking strength under the effect of light in the finished gabardines in contrast to the behavior of the non-resin-finished fabrics. Elongation and shrinkage and degree of color fading were also decreased by the resin finish.

**Planning clothes for the farm family**, D. DICKINS and A. BOWIE (*Miss. Farm Res.* [Mississippi Sta.], 5 (1942), No. 12, pp. 3-6, figs. 4).—This popular presentation of the findings of a clothing survey previously noted (E. S. R., 88, p. 424) points out that clothing should be selected, not only for comfort and cleanliness but for appearance also, since clothing fulfills a social need. As a guide for planning clothing supplies and checking the wisdom of one's own clothing choices, information from the survey is given concerning the clothes which socially active white farm families had, the prices of such garments, and the frequency in cost of replacement. This material is offered for the guidance of Mississippi farm families on the thesis that having clothes like most other people who attend the same social events is essential to an adequate, satisfying clothing supply.

**Make-overs from men's suits**, C. L. SCOTT (*U. S. Dept. Agr. Leaflet* 230 (1942), pp. 8, figs. 5).—Suggested uses are discussed briefly and illustrated, and the pattern lay-outs are diagramed.

**A B C's of mending**, C. L. SCOTT (*U. S. Dept. Agr., Farmers' Bul.* 1925 (1942), pp. 16, figs. 15).—Pointers and directions concerning patching, darning, and mending are given.

## HOME MANAGEMENT AND EQUIPMENT

[Economic studies at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt.*, 1942, pp. 2-3).—This progress report (E. S. R., 86, p. 716) concerns the survey of changes in rural living—incomes, expenditures, and savings—conducted cooperatively by this bureau and the Bureau of Labor Statistics, U. S. Department of Labor; the material prepared for groups helping families to make living adjustments in the face of the economic impact of the war; the revised plans for adequate diets at low-, moderate-, and liberal-cost levels; and the work on food commodities in relation to agricultural production goals.

[Research in economics of the household and household management by the Cornell Station] (*N. Y. State Col. Home Econ., Cornell Univ., Ann. Rpt.*, 16 (1941), pp. 17-19).—Brief progress reports are given on studies by A. Aikin, under the direction of H. Canon and L. J. Williamson, on credit bureaus from the consumer's point of view; by E. K. Bennett, under the direction of E. M. Cushman and Canon with the assistance of M. Thompson, on the methods of maintaining felt-base floor coverings in home kitchens; by E. Knowles, under the direction of Canon and Cushman, on home-laundering tasks in relationship to the worker and the equipment; and by Williamson on the determination of practicable methods for the use of homemakers in selecting soaps and other water-softeners. A summary is also given of a completed study by M. Spicer, under the direction of Canon and Cushman, on major equipment, work space, and storage space with reference to common household tasks in 160 farm and village homes.

**Summary of family classification, farm privilege, and cash cost of living**, V. E. SCOTT and P. SWETT (*Farm Mangt. Bul.* [Nevada Sta.], 3 (1942), No. 4, pp. [1]+11+[12], figs. 3).—Data from 133 home account records, 64 obtained in 1940 and 69 in 1941, were summarized by size of income (low, under \$2,500; medium, \$2,501-\$5,000; high, over \$5,000) and size of family groups (under three, from three to five, and over five). The summaries indicated that in 1940-41 the general level of income (\$6,726 gross and \$5,598 cash) was higher than in 1939.

In 1939 the families were nearly equally divided among the three groups, while in 1940-41 nearly half were in the high group. In the higher income group more money was spent for home investments and the percentage of income used for this purpose was larger. Included under home investments were expenditures for new homes, furniture, home repairs, and new automobiles; the three latter items amounted to from 9 to 28 percent of the total cash expense. Total cash home expense averaged \$1,678 for all groups and included an average of \$1,273 for cash living; the balance, an average of \$405, for cash home investments represented nearly a fourth of the total cash home expense, and 6 percent of the average gross income. Total living expense included the cash expended for household and for personal items plus farm privilege, the latter consisting of the value of farm produce used in the home plus the rent value of the house, which was calculated at 10 percent of the beginning inventory value. Cash expenses averaged about 75 percent of the total expense (\$2,332), varying from 63 to 81 percent. Rent of dwelling constituted from 5 to 21 percent, and the value of the farm produce varied from 7 to 23 percent of the total cash expense. The values of cash living, rent, and farm produce used increased as income and size of family increased.

Food, personal expenses (including health, recreation, and development), and clothing accounted, respectively, for 31, 38, and 11 percent of the total cash family living expense. The latter increased as the size of the family increased, but expense per person was greater in the smaller sized families and was reduced as the family size increased. The value of home-produced foods increased as income increased, and within each income group increased as the size of the family increased. A high percentage of the family needs was produced on the farm.

[Factors affecting the expenditures for family living among Kansas farm families] (*Kansas Sta. Bien. Rpt. 1941-42, pp. 62-63*).—Progress is reported by M. A. Gunselman and W. E. Grimes in the analysis of data from over 800 farm family account books.

[Household equipment and housing at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1942, pp. 9-10*).—This annual report (E. S. R., 86, p. 716) notes that work was directed toward (1) development of performance standards for new equipment built of substitute materials and for rebuilt equipment and (2) development of standard test procedures. Housing researches toward establishing minimum requirements for working and storage space in kitchens were carried forward.

## MISCELLANEOUS

**The farmers' handbook**, edited by K. SYNNOTT (*Sydney, N. S. Wales: Dept. Agr., 1941, 5. ed., pp. VIII+1028, figs. [591], map. 1*).—A revision and enlargement of the book noted earlier (E. S. R., 37, p. 888).

**University of Alaska Agricultural Experiment Stations, College, Alaska: Eighth Progress Report, 1938, 1939, 1940, 1941**, L. T. OLDROYD (*Alaska Stat. Prog. Rpt. 1938-41, pp. 42, figs. 7*).<sup>4</sup>

**Fifty-fourth Annual Report [of Georgia Station, 1942]**, H. P. STUCKEY (*Georgia Sta. Rpt. 1942, pp. 111, figs. 14*).<sup>4</sup>

**Eleventh Biennial Report of the [Kansas Station, 1941-42]**, L. E. CALL ET AL. (*Kansas Sta. Bien. Rpt. 1941-42, pp. 79, figs. 2*).<sup>4</sup>

**Value of agricultural research in wartime: Forty-eighth and Forty-ninth Annual Reports of the Montana Agricultural Experiment Station,**

<sup>4</sup> The experimental work reported is for the most part noted elsewhere in this issue.

[1941-42], R. T. CLARK ET AL. (*Montana Sta. [Bicn.] Rpt. 1941-42*, pp. 63, fig. 1).<sup>4</sup>

Oregon's agricultural research aids national defense: Biennial Report [of Oregon Station 1939-40], R. S. BRASE (*Oregon Sta. Bul. 401 (1941)*, pp. 92, figs. 41).<sup>4</sup>

Science for the farmer: Fifty-fifth Annual Report of the Pennsylvania Agricultural Experiment Station, [1942], [S. W. FLETCHER] (*Pennsylvania Sta. Bul. 429 (1942)*, pp. [4]+44, figs. 16).<sup>4</sup>

Report of the Puerto Rico Experiment Station, 1941 [A. LEE ET AL.] (*Puerto Rico Sta. Rpt. 1941*, pp. [2]+24).<sup>4</sup>

Bimonthly Bulletin, [November 1942] (*North Dakota Sta. Bimo. Bul. 5 (1942)*, No. 2, pp. 50, figs. 7).—In addition to several articles noted elsewhere in this issue, this number contains Herd Sires in Service on the Dairy Herds at N. D. A. C., by J. R. Dice (pp. 15-16); and Publications of the Staff of the North Dakota Agricultural Experiment Station and of Cooperating Federal Agencies Assigned to the Station During the Station Year July 1, 1941, to June 30, 1942 (pp. 17-26) and Searching for Farm Facts—Current Investigations of the North Dakota Agricultural Experiment Station (pp. 33-49), both by H. L. Walster.

Farm and Home Science, [December 1942] (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 4, pp. 12, figs. 17).—In addition to articles noted elsewhere in this issue this number contains Dividends From Investment of Funds in Agricultural Research, by R. H. Walker (pp. 2, 12); Conservation of the Nutritive Values of Lamb and Tomatoes Studied at Station (p. 2); and Results of Station Research Have Practical Applications to War Emergency Agricultural Production Problems (pp. 6-8, 10).

<sup>4</sup> The experimental work reported is for the most part noted elsewhere in this issue.

## NOTES

---

**Arkansas University and Station.**—Recent enrollments for military service include T. R. Hedges, professor of rural economics and sociology; W. R. Horsfall, assistant professor of entomology and assistant entomologist; Arthur H. Thompson, instructor in agricultural engineering; and Don A. Marshall, instructor and assistant in rural economics and sociology. Tildon Easley has been appointed instructor in agronomy, and Xzin McNeal, instructor in agricultural engineering.

**Colorado College and Station.**—As the process of cracking beet seed to increase the number of single plants results in approximately one-half usable seed and one-half discard, the station has been studying the discard as a possible livestock feed since there are about 1,000 tons of this material available each year in the State. Chemical analysis revealed 13 percent of protein. Seed of mallow, common sowthistle, alfalfa, and some viable beet seeds were found.

In a 120-day test of drenching for parasite control the experimental lambs brought \$15.75 per 100 lb., the day's top price for trucked-in lambs. One indication shown by the test is that two drenchings will prevent condemnation of livers due to fringed tapeworm infestation.

H. S. Wilgus, Jr., head of the poultry section, has accepted a captaincy in the food and nutrition division of the Sanitary Corps, U. S. Army. W. E. Connel, area conservationist in the U. S. D. A. Soil Conservation Service, has been appointed to take charge of research in feeding beef cattle, dairy cattle, sheep and lambs, and hogs.

**Kansas College and Station.**—The Kansas Industrial Commission has allotted \$25,000 for additional research on dehydration of farm products. A laboratory will be set up at the college under the direction of the department of chemistry.

The resignations are noted of C. K. Ward, associate professor of economics and sociology; Dr. J. A. Weybrew, assistant chemist; and J. W. Mather, extension assistant professor of agricultural economics (marketing). The last named has been succeeded by Dwight S. Tolle. Leave of absence to enter military service has been granted C. J. Birkeland, research assistant in horticulture; James W. Martin, assistant professor in agricultural engineering; and Dr. C. H. Whitnah, assistant professor in chemistry and dairy chemist. Thomas Thomson, instructor in the department of chemistry in the School of Arts and Sciences, has been transferred to the station staff as assistant chemist to take over the industrial research formerly assigned to Henry S. C. Lau, resigned.

**Minnesota Station.**—Two new apple varieties developed by the station have been announced as ready for general release. Victory, or Minnesota 396, is much like McIntosh in quality and aroma, but is more resistant to scab, hangs better on the tree, and packs and keeps more satisfactorily, while the tree is more winter-hardy in Minnesota. A second variety, named Fireside, or Minnesota 993, is of the Delicious type, large, roundish-conic in shape, medium red in color, and approaches the ideal of a winter keeper.

Dr. L. S. Palmer, professor of agricultural biochemistry, has been appointed chief of the division of agricultural biochemistry. Dr. J. W. Nelson, research fellow in biochemistry, has become research chemist in nutrition for Cargill, Inc., and has been succeeded by Dr. Floyd C. Olson, formerly assistant chemist in the West Virginia Station.

**Mississippi Station.**—Dr. H. H. Foster, plant pathologist of the Tobacco Institute of Puerto Rico, has been appointed plant pathologist of the Truck Crops Branch Station, replacing Dr. F. J. LeBeau, resigned to accept a position in Mexico with the U. S. D. A. Bureau of Plant Industry, Soils, and Agricultural Engineering, in its rubber investigations. Mr. Foster will also serve as acting superintendent, pending the return of John A. Campbell, who is now with the armed services. H. A. York, in charge of cotton and soybean work at the Delta Branch Station, has been appointed superintendent of the Raymond Branch Station. Dr. C. H. Ragland, professor of horticulture, has reported to the U. S. Army as a reserve officer. George V. Young, assistant plant pathologist of the U. S. Department of Agriculture, has been transferred to the department of plant pathology at State College, where he will undertake studies in corn diseases.

**Washington Station.**—Dr. Earl J. Anderson, associate pathologist in the Hawaiian Pineapple Growers Association, has been appointed head of the division of plant pathology. Clarence Lounsbury, assistant in the U. S. D. A. Soil Survey, has been appointed soil surveyor vice R. H. Fowler, who is on leave for military service.

**West Virginia University and Station.**—Hazel Cameron, research associate in nutrition, has resigned to accept a position in the State Department of Public Health. Staff members on leave for military service include Lowell Besley, associate forester; R. H. Black, assistant in animal husbandry; W. M. Broadfoot, assistant in agronomy; J. B. Byers, assistant in forestry; Torkel Holsoe, assistant forester; L. J. Manus, assistant in dairy husbandry; A. S. Margolin, photographic assistant; J. F. McMurray, assistant in wildlife management; O. M. Neal, Jr., assistant in horticulture; and T. D. Runnels, assistant in poultry husbandry. W. W. Armentrout, agricultural economist, is on leave as area rent director, Office of Price Administration, for Monongalia and Marion Counties.

**Nutrition Foundation.**—Grants for the coming year of \$148,550 have recently been announced, including \$110,700 for the renewal of 28 projects supported during 1942 and \$37,850 for 15 new projects. Among the institutions receiving new grants are the University of Wisconsin, the University of California, the Massachusetts State College, Cornell University, the Oregon State College, and the Oklahoma Experiment Station.

**Cooperative Experiment Stations in Latin America.**—Recent personnel announcements in *USDA* for the cooperative experiment stations established in Nicaragua, Ecuador, and Peru include the following: Nicaragua (Recreo), Robert L. Pendleton, director; P. L. Guest, horticulturist; Arthur G. Kevorkian of the Puerto Rico Federal Station, pathologist; and S. H. Work, animal husbandman. Ecuador (Quevedo), Lee Hines, director, assisted by Lewis E. Long and Lewis H. McCann. Peru (Tingo Maria), Benjamin J. Birdsall, director; Rolland C. Lorenz, pathologist; and Harold J. Brooks, animal husbandman; and William L. Wickline, extension specialist.

The Peruvian station at Tingo Maria is located on a tract of about 13 acres on the Huallaga River on the eastern slope of the Andes and will be devoted to encouraging the large-scale production of rubber, quinine, and other products formerly obtained from the Far East. The plant will consist of 3 main buildings and 20 residences, costing in excess of \$160,000. The principal buildings will comprise a head house plant with the main laboratories and greenhouses, an administration building with offices and a library, and a dormitory or club house for single men.

## RECENT WORK IN AGRICULTURAL SCIENCE

---

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Bureau of Agricultural Chemistry and Engineering] (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin. Rpt., 1942, pp. 2-36*).—The principal subjects on which data are reported are agricultural chemical investigations, including new applications of the brining process, preparing fruits for overseas shipment, alcohol from citrus-waste liquors, new fruit products and byproducts, cereals and seed products, eggs and poultry meat for export, more sugar from domestic sources, coffee-sugar tablets for the army, sorgo sirup as a source of alcohol, byproducts from sorgo and sugarcane, sweetpotato vines and tubers for feed, feeding value of hemicelluloses, vegetable oils, how grain storage affects proteins, improving the protein value of foods, prevention of bin burning in grain, and control of enzymes to conserve foods; special research in agriculture, including research on fast-drying oil from soybeans and plastics from soybean meal; regional research laboratories, including work on synthetic rubber, the rubber substitute Norepol, starches from waxy corn and sorghum, plastics from agricultural residues, cork substitutes from residues, penicillin, a new antiseptic agent from corn sugar, lint cotton for smokeless powder, replacing imported fibers with cotton, processing cotton for military uses, novel defense uses for cotton, recovery of seed oils from press cake, replacing imported oils with modified domestic oils, expanding uses of oilseed meals, starch and carotene from sweetpotatoes, processing fruits for food, emergency uses for apples, industrial products from fruit wastes, using plant pigments of alfalfa, packing poultry products by freezing, preserving eggs without refrigeration, utilizing poultry wastes, preserving vegetables by freezing, utilizing vegetable wastes, nicotine and nicotinic acid from tobacco, industrial products from milk proteins, intermediates for synthetic resins and rubber from lactic acid, preventing rancidity in animal fats, uses for potato starch and derivatives, developing domestic tanning materials and chrome-saving tannages, and conserving domestic hides and skins; and naval stores investigations, including those on potential synthetic-rubber intermediates and other products from turpentine, separating turpentine into components, getting stable resins from pine gum, rosin products to replace scarce ones, military uses for naval stores, and wartime changes in making, handling, and storing naval stores.

**Flocculation and electrokinetic behavior of two deferrated soil colloids,** S. J. TORR. (*N. J. Expt. Stas.*). (*Soil Sci., 53 (1942), No. 4, pp. 265-272*).—The removal of Fe and Al from soil colloids by the free iron oxide method and

by electrodialysis produced colloidal residues, the chemical and electrokinetic properties of which differed widely from those of the untreated colloids.

The concentration of HCl required for flocculation of deferrated Na-colloids was not markedly different from that required for flocculation of the untreated Na-colloids, but the cataphoretic charge associated with the deferrated colloids was generally higher than that of the untreated colloid. The concentration of  $\text{H}_2\text{SO}_4$  required for flocculation was approximately the same for the untreated colloid as for the deferrated residue, but the concentration required for flocculation increased with further deferration. The most marked effects from deferration were noted in the  $\text{H}_3\text{PO}_4$  system, and particularly in the more fully deferrated residues of this series, the flocculating concentration of acid increasing from 1.5 to 2.0 milliequivalents per liter with the more fully deferrated residues of the Colts Neck colloid and from 1.0 to 2.0 m. e. with the more fully deferrated residues of the Penn colloid. Deferration lowered the isoelectric pH of the colloids, and these lowerings were correlated with decreased ultimate pH values in water and in  $\text{N KCl}$ . The differences in electrokinetic behavior and flocculation between the deferrated and the untreated colloids are explained on the basis of basoid removal during deferration and electrodialysis.

**The formation of cysteine from homocysteine and serine by liver tissue of rats,** F. BINKLEY and V. DU VIGNEAUD (*Jour. Biol. Chem.*, 144 (1942), No. 2, pp. 507-511).—The conversion of a mixture of homocysteine and serine to cysteine by liver tissue of rats has been demonstrated. In the absence of serine only slight cysteine formation was observed. Homocysteine was found far more effectively converted than was methionine. The possible significance of these findings in conjunction with the biological behavior of the unsymmetrical thio ether,  $\text{H-S-(}\beta\text{-amino-}\beta\text{-carboxyethyl)homocysteine}$  (cystathionine), is discussed.

**The formation of cysteine from  $\text{H-S-(}\beta\text{-amino-}\beta\text{-carboxyethyl)homocysteine}$  by liver tissue,** F. BINKLEY, W. P. ANSLOW, JR., and V. DU VIGNEAUD. (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 559-560).—The formation, in an experiment carried out in vitro, of 7.8 mg. of cystine from 50 mg. of the homocysteine derivative was indicated by a colorimetric method; and after precipitation of the cystine as the cuprous mercaptide and removal of the copper, 6 mg. of cystine was found by the Sullivan method.

**The critical peptization temperatures of zein in concentrated ethyl alcohol,** R. H. MANLEY and C. D. EVANS. (U. S. D. A.). (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 701-702, fig. 1).—Working under the rigid exclusion of moisture, the authors demonstrated that zein is dispersible in concentrated aqueous alcohol as well as in absolute alcohol at temperatures above the normal boiling point of the solvent. The curve accompanying the paper shows critical temperatures ranging from about  $120^\circ\text{C}$ . in absolute alcohol to a minimum between  $0^\circ$  and  $-10^\circ$  for alcohol concentrations between 70 and 80 percent. From 70 percent down to 40 percent of alcohol the critical temperature is shown as rising again to a temperature between  $50^\circ$  and  $60^\circ$  at the 40-percent alcohol concentration.

**Isolation of mesolanthionine from various alkali-treated proteins,** M. J. HORN, D. B. JONES, and S. J. RINGEL. (U. S. D. A.). (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 87-91).—Lanthionine (E. S. R., 87, p. 166), has now been isolated (1 percent) from acid hydrolyzates of hair pretreated by being boiled for 1 hr. with 0.1  $\text{N NaOH}$  solution. Dilute alkali reacts with wool even at relatively low temperatures. Lanthionine (0.1 gm.) also was isolated from 100 gm. of wool that had been suspended in 2-percent solution of  $\text{Na}_2\text{S}$  for 6 days at  $37^\circ\text{C}$ . In addition there was obtained about an equal amount of

another compound having properties similar to lanthionine but more soluble and differing in crystal form.

**Isolation of *dl*-lanthionine from various alkali-treated proteins**, M. J. HORN, D. B. JONES, and S. J. RINGEL. (U. S. D. A.). (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 93-97, figs. 2).—An isomeric thio ether amino acid, previously observed accompanying mesolanthionine in approximately the same proportion in the hydrolyzates of certain alkali-treated proteins, has been isolated from  $\text{Na}_2\text{CO}_3$ -treated human hair. Because it is optically inactive, but differs from mesolanthionine in solubility and crystalline form, and because it agrees closely in its properties and crystalline form with those given for the synthetic *dl*-lanthionine, this compound seems definitely identifiable as *dl*-lanthionine. Although sparingly soluble in water, it is approximately seven times as soluble as mesolanthionine. It possesses the property of dimorphism and crystallizes from dilute ammonia as lustrous, elongated hexagonal plates, decomposing at  $283^\circ\text{--}284^\circ$  [C.], but separates from water as crystals belonging to a different crystal system and having several different crystal habits.

**Carbohydrate characterization.—III, The identification of hexuronic or saccharic acids as benzimidazole derivatives**, R. LOHMAR, R. J. DIMLER, S. MOORE, and K. P. LINK. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 551-556).—The method of two of the present authors for characterizing certain aldmonosaccharides by oxidizing with an alkaline hypolodite to the corresponding aldonic acid and condensing the acid with *o*-phenylenediamine (E. S. R., 86, p. 435) has been extended to cover hexuronic acids. These are similarly oxidized to the corresponding saccharic acids, and these dibasic acids are condensed with 2 molecular equivalents of the diamine to form dibenzimidazoles. The method as here described was specifically adapted for the identification of the naturally occurring hexuronic acids, *d*-glucuronic, *d*-mannuronic, and *d*-galacturonic, as dibenzimidazole derivatives of the corresponding saccharic acids. The applicability of the procedure was tested on hexuronic acids, glycuronides, and polyuronides.

**The characterization of lactic acid as the benzimidazole derivative**, R. J. DIMLER and K. P. LINK. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 557-558).—The racemic 2-( $\alpha$ -hydroxyethyl)-benzimidazole formed from lactic acid and *o*-phenylenediamine was found to have the melting point  $179^\circ\text{--}181^\circ$  C., its hydrochloride to melt at  $211^\circ\text{--}213^\circ$ , and its silver salt to be a form in which the compound may be almost completely isolated. The isolation of the compound as its silver salt was found an especially convenient method of preparing it.

**The dissociation constants of hydroxylysine**, F. W. KLEMPERER, A. B. HASTINGS, and D. D. VAN SLYKE (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 433-437, figs. 2).—The dissociation constants of hydroxylysine were determined at  $38^\circ$  [C.] as  $\text{pK}'_1=2.13$ ,  $\text{pK}'_2=8.62$ , and  $\text{pK}'_3=9.67$  as compared with those of lysine,  $\text{pK}'_1=2.20$ ,  $\text{pK}'_2=8.90$ , and  $\text{pK}'_3=10.28$ . These data confirm the view that the hydroxy group is attached in the  $\delta$  or  $\epsilon$  position to the carbon atom adjacent to that carrying the amino group.

**Prolactin**, A. WHITE, R. W. BONSNES, and C. N. H. LONG (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 447-464, figs. 5).—From a highly purified amorphous preparation of beef prolactin it was shown to be possible to prepare a crystalline protein with a lactogenic activity very similar to that of the amorphous product. The homogeneity of this protein was indicated by studies of its electrophoresis, ultracentrifugation, and solubility measurements. The sedimentation constant, diffusion constant, approximate molecular weight, isoelectric point, elementary analysis, tyrosine, tryptophan, and cystine content, heat stability at various pH

values, and the alterations in biological activity occurring when the protein was hydrolyzed with acid, pepsin, or trypsin were also determined. The data obtained confirm the supposition of the protein nature of this hormone.

**Adipic acid as an oxidation product of the diaminocarboxylic acid derived from biotin.** K. HOFMANN, D. B. MELVILLE, and V. DU VIGNEAUD (*Jour. Biol. Chem.*, 144 (1942), No. 2, pp. 513-518).—Oxidation of the diaminocarboxylic acid derived from biotin, either with nitric acid or with permanganate, yielded adipic acid as one of the oxidation products. That one of the carboxyl groups of the adipic acid is the original carboxyl group in the biotin molecule is indicated by the nonappearance of adipic acid among the oxidation products of the amine formed by a Curtius rearrangement of biotin hydrazide.

**The in vitro formation of thyroxine and diiodotyrosine by thyroid tissue.** M. E. MORTON and I. L. CHAIKOFF (*Jour. Biol. Chem.*, 144 (1942), No. 2, p. 565).— $I^{131}$  was added as iodide. At the end of 3 hr., the distribution of  $I^{131}$  among iodide, diiodotyrosine, and thyroxine in the tissue plus its surrounding medium was 1:6:1. In 3 hr. as much as 12 percent of the  $I^{131}$  added to the bath was found as thyroxine and as much as 70 percent as diiodotyrosine.

**Gluconic acid production: Repeated recovery and re-use of submerged *Aspergillus niger* by filtration.** N. PORGES, T. F. CLARK, and S. I. ARONOVSKY. (U. S. D. A. coop. Iowa State Col.). (*Indus. and Engin. Chem.*, 33 (1941), No. 8, pp. 1065-1067, figs. 2).—In the semicontinuous method of producing gluconic acid from glucose by *A. niger*, the mycelia were recovered by pressure filtration and reused in nine successive fermentations of media containing 16 gm. of glucose per 100 cc. In the fermentation of a solution containing 16 gm. of glucose and about 2.6 gm. of calcium carbonate per 100 cc., the uncombined gluconic acid is present in sufficient concentration to prevent the formation of calcium gluconate crystals which tend to mat with the mycelial growth and thus hinder filtration. This filtration permits the utilization of a full charge of fresh medium of higher glucose concentration than was feasible with the flotation method. In the cases where the free acid concentration was low, centrifugal filtration was the more efficient method of removing the mycelia from the fermented liquor.

**Glutamine and glutamic acid as growth factors for lactic acid bacteria.** M. A. POLLACK and M. LINDNER (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 655-661).—Acid-producing bacteria comprising 6 strains of *Streptococcus lactis* and cultures of *Lactobacillus pentosus*, *L. arabinosus*, and *L. Casei* were shown to require either glutamine or glutamic acid for growth. Of these organisms, 5 responded as well to glutamic acid as to glutamine, but the other 4 required at least 11 times as much acid as amide to produce the same effect.

It is held unlikely that glutamic acid functions through the amide, because both forms are equally potent on an ammonia-free medium in some cases and the addition of a high concentration of ammonium chloride produces only a minor increase in the effectiveness of glutamic acid. None of the bacteria tested could produce glutamine from glucose and ammonium salts. The mechanism believed to be most likely is that the bacteria require glutamine or glutamic acid simply for the construction of cell proteins, particularly in view of the fact that the requirements of these amino acids are of the order of magnitude which would be expected for this use.

**Distribution of isotopic nitrogen in *Azotobacter vinelandii*.** R. H. BUREIS (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 509-517, fig. 1).—*A. vinelandii* cells supplied with molecular  $N^{15}$  for 90 min. after an initial period of 18 hours' growth in normal nitrogen were fractionated to determine the distribution of total nitrogen and isotopic nitrogen. Arginine and histidine were present in large quantities but carried low levels of  $N^{15}$ . "Amide" nitrogen and three

copper salt fractions of the monoamino acids gave intermediate values for the  $N^{15}$  isotope, whereas the lysine fraction was somewhat higher in  $N^{15}$ . Among the amino acids, glutamic acid and the aspartic acid fraction showed the highest levels of  $N^{15}$ . The Neuberg filtrate was high and the extracellular nitrogen of the culture was low in isotope concentration.

The data are discussed in relation to proposed mechanisms of biological nitrogen fixation.

**An enzymatic conversion of radioactive sulfide sulfur to cysteine sulfur,** C. V. SMYTHE and D. HALLIDAY (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 237-242, fig. 1).—Cysteine and hydrogen sulfide containing radioactive sulfur have been added to an enzyme preparation which converts cysteine to pyruvic acid, ammonia, and hydrogen sulfide. When the nitrogen of part of the added cysteine had been converted to ammonia, the reaction was stopped and the remaining cysteine was isolated. It contained appreciable amounts of radioactive sulfur, thus demonstrating the formation of cysteine sulfur from sulfide sulfur under these conditions.

**Oxidation, reduction, and sulphydryl in autolysis,** B. BAILEY, S. BELFER, H. EDER, and H. C. BRADLEY. (Univ. Wis.). (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 721-728, figs. 3).—The authors obtained results suggesting the presence of two enzymes concerned in the primary cleavage of the tissue proteins. One of these is active whether cysteine is present or not, and in the absence of the activator autolysis goes on slowly to reach a cleavage level determined by the active masses of substrate and products. The second enzyme requires sulphydryl activation. When this is provided, digestion is much more rapid but the same final degree of cleavage is attained. The effect of cysteine is to produce more active proteinase in the mixture rather than more available protein.

**Conversion of estrone to estriol in vivo,** W. H. PEARLMAN and G. PINCUS (*Jour. Biol. Chem.*, 144 (1942), No. 2, pp. 569-570).—A total of 1.05 gm. of oestrone acetate, m. p. 124°-125° [C.], was dissolved in oil and injected intramuscularly into healthy young men. The pooled urines (30.7 l.) subsequently collected were extracted with ether after acid hydrolysis. The phenols were taken up in benzene and extracted with 0.3 M sodium carbonate in order to obtain the oestriol fraction and the procedure repeated. Further purification of this fraction (approximately 30,000 r-units) gave 10.3 mg. of semicrystalline material, which yielded from ethyl acetate 1.6 mg. of crystals, m. p. 266°-268°. Recrystallization from the same solvent gave 0.6 mg., m. p. 269°-270°; a mixed melting point determination with authentic oestriol, m. p. 271°-273°, gave 268°-272°. The oestrogenic potencies of both preparations were identical; both gave an identical color reaction spectrum. An additional 2 mg., m. p. 268°-270°, were obtained from the mother liquors.

**A green pigment-producing compound in urine of pyridoxine-deficient rats,** S. LEFKOVSKY and E. NIELSEN. (Univ. Calif.). (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 135-138, figs. 2).—Pyridoxine-deficient rats were found to excrete an unidentified compound convertible to a green pigment by ferric ammonium sulfate. The pigment acted as an indicator to acids and bases, turning a light yellow in strongly acid solution and yellow in strongly basic solution. Administration of pyridoxine to the deficient rats stopped the excretion of the precursor of the green pigment in a few hours. Some of the properties of the green pigment are discussed.

**Non-hemin and total iron in bull spermatozoa,** C. A. ZITTLE and B. ZITIN (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 105-112).—The total iron content of dried lipide-free bull spermatozoa was determined colorimetrically, with the thiocyanate, thioglycolic acid, and o-phenanthroline reagents, to have a mean

value of 0.0071 percent. The iron content of parts of the spermatozoa prepared from spermatozoa broken by sonic vibrations and homogenization was also determined, but the accuracy was considered to be impaired by contamination from the apparatus used. Definitely more iron was present in the midpieces and tails of the spermatozoa than in the heads, however. Cytochrome *c* could not be detected spectroscopically.

The nonhemin iron of bull spermatozoa was estimated to be 60 percent of the total iron. Similar determinations on bull testicles were made. Experiments showing that the method used, extraction with hot pyrophosphate, was not limited by the formation of an insoluble iron-pyrophosphate compound are also recorded.

**The amount and distribution of cytochrome oxidase in bull spermatozoa,** C. A. ZITTLE and B. ZITIN (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 99-104).—The molecular oxygen consumed by spermatozoa, disintegrated by grinding or by sonic treatment, with *p*-phenylenediamine as the substrate in the presence of excess cytochrome *c* at 37° [C.], was used as a measure of cytochrome oxidase. An average O<sub>2</sub> consumption of 25 mm.<sup>3</sup> per milligram per hour was found with sonically treated spermatozoa. The O<sub>2</sub> consumption by the parts of the spermatozoa in the same test system was heads 1.2, midpieces 14.4, and tails 29.1 mm.<sup>3</sup> per milligram per hour. These differences are discussed in relation to the function of the different parts. In similar experiments with sodium succinate as the substrate, the results were of the same magnitude as those with *p*-phenylenediamine. With hydroquinone as the substrate the O<sub>2</sub> consumption was smaller, particularly so with the ground spermatozoa, with which it was negligible. Measurements made at 20° showed a similar variation with the different substrates. Some O<sub>2</sub> was taken up by the preparations of spermatozoa (5.1 mm.<sup>3</sup> per milligram per hour with sonically treated spermatozoa) with *p*-phenylenediamine when no cytochrome *c* was added.

**Enzymes of the fig,** A. WOOD. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1942), No. 10, pp. 308-310, 317).—This article is a compilation of the observations of a number of investigators. Topics dealt with are the proteolytic enzyme of the fig, its activation, and the proteinase substances which have been found to be attacked by it; ficin and the crystalline enzyme of the fig; seasonal variation in proteolytic activity; optimum pH value; inactivation temperature; etc. Of oxidizing enzymes the peroxidase and the catalase are discussed. One reference to the presence of amylase in the latex of *Ficus carica* is cited.

**Further observations concerning the preparation and properties of catalase from different sources.**—I, Crystalline lamb liver catalase. II, Preparation of crystalline beef liver catalase by use of acetone or alcohol, A. L. DOUNCE. (Cornell Univ.). (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 497-501, fig. 1).—The crystallization and properties of lamb liver catalase are described. Methods for the preparation of crystalline beef liver catalase by the substitution of alcohol or acetone for the solvent dioxane, originally employed, are given. Catalase prepared by using alcohol or acetone is practically identical with that obtained by the dioxane method.

**Dairy glassware is carefully checked** (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, p. 20).—From June 16, 1941, to May 15, 1942, the station checked the accuracy of 46,963 pieces of milk- and cream-testing glassware, finding only about 1.5 percent to be defective.

**Note on an accurate wet combustion method for the determination of carbon in soils,** P. ALPER (*Jour. Agr. Sci. [England]*, 32 (1942), No. 4, p. 389).—An improvement in the apparatus used in making the determination is presented.

**Improved procedure for preparation of carcasses of small animals and skeletal parts of larger animals for chemical analysis,** G. LEAVELL (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 1, pp. 159-163).—The procedures described involve autoclaving at 15 lb. pressure in sealed containers for periods of from 3 to 8 hr., depending upon the nature of the samples, and subsequently grinding in a chilled or frozen state. The autoclaved samples are sterile and may be stored indefinitely before being ground. Since the final mixtures are of mushy consistency, samples for final analysis are best weighed by difference from covered weighing bottles. Results of ash determinations on the sample prepared as recommended and on fractions obtained during grinding indicate that the procedure described provides representative samples, but that parts trapped in the grinder must be removed and crushed and added to the main portion, since it is the high ash containing parts that tend to be trapped. Observations on the efficiency of two grinders of different design of fluting are presented.

**Conductometric determination of ammonia: Application to nitrogen distribution studies,** R. H. HENDRICKS, M. D. THOMAS, M. STOUT, and B. TOLMAN. (U. S. D. A. et al.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, pp. 23-26, fig. 1).—The absorption of ammonia by boric acid after vacuum distillation or volatilization by aspiration was satisfactorily accomplished if sintered-glass bubblers and sufficient excess of boric acid were employed. It may be necessary to use butyl alcohol in the absorbing solution in some cases. The change in the conductance of the solution provided a simple and accurate method of measuring the amount of ammonia absorbed. Although sulfuric acid is a better ammonia absorbent than boric acid and gives a larger change of conductance, boric acid is preferred in general use because of its convenience. Sulfuric acid may be more suitable in some cases, particularly in microanalyses. The method was applied to nitrogen distribution studies of plant materials and to automatic determination of traces of ammonia in air.

**The investigation of amino acid reactions by methods of non-aqueous titrimetry, I-III** (*Jour. Biol. Chem.*, 144 (1942), No. 1, pp. 193-227, figs. 2).—The first of these three papers notes work on general behavior of amino acids in titrations with perchloric acid in acetic acid solution, the second deals especially with the hydroxyamino acids, and the third with a method of quantitative determination based on acetylation of hydroxy, amino, and, in part, sulphydryl groups.

**I. Acetylation and formylation of amino groups,** J. J. Kolb and G. Toennies (pp. 193-201).—An exploratory study of the rates of formation of N-acetyl and N-formyl derivatives of amino acids by the action of acetic anhydride and formic acid-acetic anhydride in acetous solutions was made. It was found that the course of these reactions can be followed by titration with perchloric acid in acetic acid solution, because of the loss of basicity resulting from acylation of amino groups, and that the acetamido and formamido groups possess definite residual basic properties which are different and characteristic for each type.

**II. Differential acetylation of hydroxy groups, and a method for the preparation of the O-acetyl derivatives of hydroxyamino acids,** W. Sakami and G. Toennies (pp. 203-217).—Investigation of the reactions of hydroxyamino acids with acetic anhydride, in acetic acid in the presence of perchloric acid, showed that while the acetylation of amino groups is increasingly suppressed by increasing acidity the acetylation of hydroxy groups is catalytically promoted by the perchloric acid. The consumption of acetic anhydride is determined in these experiments by a titrimetric method which is based on the fact that amino groups on acetylation tend to lose their basic properties with respect to acetous

perchloric acid. It was found that in the aceteous system, in the presence of excess perchloric acid, the hydroxyamino acids may be quantitatively acetylated solely on the hydroxyl group. A method for the preparation of the new compounds O-acetylhydroxyproline, O-acetylserine, O-acetylthreonine, and O-acetyltyrosine, based on the findings outlined, is presented. The method was found useful for the preparation of other related compounds.

III. *The determination of hydroxy (and analogous) groups in amino acids*, G. Toennies and J. J. Kolb (pp. 219-227).—It is shown that hydroxy and analogous ( $-\text{NH}-$  of tryptophan,  $=\text{NH}$ , and, imperfectly,  $-\text{SH}-$ ) groups can be determined in dry amino acids by an aceteous titrimetric method based on the acid-catalyzed acetylation of these groups by acetic anhydride. The evidence obtained indicates that the reaction employed may furnish a way for preparing the unknown S-acetylcysteine, the imino-N-acetyl derivative of arginine, and the indole-N-acetyl derivative of tryptophan. Among the amino acids studied, cystine showed an exceptional behavior in that it reduced perchloric acid under the prevailing conditions. Diphenylguanidine was found a suitable primary standard for aceteous perchloric acid.

**A du Pont type semimicronitrometer**, P. J. ELVING and W. R. McELROY. (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, pp. 84-88, figs. 4).—The instrument described is of the compensating type, the quantity of gas being read at the volume it would occupy at standard conditions of temperature and pressure. Two models of the nitrometer were developed, one hand-shaken like the macronitrometers and the other motor-shaken. Various inorganic and organic nitrates, including nitrocelluloses, were successfully analyzed.

**A new color test for tryptophane in protein hydrolysates**, A. A. ALBANESE and J. E. FRANKSTON (*Jour. Biol. Chem.*, 144 (1942), No. 2, pp. 563-564).—The protein sample was hydrolyzed by being boiled under a reflux for from 20 to 22 hr. with 5 cc. of 20 percent NaOH per gram of sample. The hydrolyzate was neutralized to pH 7 with glacial acetic acid. Silica (from slight distintegration of the glass vessel) was filtered off and the volume of the filtrate adjusted so that 2 cc. contained approximately 1 mg. of tryptophan. A 2-cc. sample of filtrate in a colorimeter tube marked at 5 cc. was treated with 0.3 cc. of sodium nitrite and 0.1 cc. of 10 percent acetic acid and the mixture shaken intermittently for 10 min. There were then added 0.3 cc. of potassium persulfate (1 percent), 0.5 cc. of thymol (1 percent in 95 percent ethanol), and 5 cc. of a mixture of 3 parts of 40 percent trichloroacetic acid and 2 parts of concentrated hydrochloric acid, with thorough mixing after each addition. The tube was immediately placed in a boiling water bath for 5 min. and cooled in an ice bath for 5 min. The sample separated into two layers—an almost colorless aqueous layer above and a red layer of ethyl trichloroacetate below. All but approximately 0.3 cc. of the upper aqueous layer was then removed by a capillary pipette, and the colored layer was diluted to the 5-cc. mark with glacial acetic acid. The resulting color was read in a photoelectric colorimeter with a suitable filter and compared with that of a similarly treated tryptophan standard.

**Colorimetric microdetermination of arsenic after evolution as arsine**, E. B. SANDELL. (Univ. Minn.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, pp. 82-83, figs. 2).—The method described is based on the absorption of arsine in an acid solution of mercuric chloride containing permanganate. **Arsine** is oxidized in one step to arsenate, and arsenic can then be determined in the solution by adding an excess of ammonium molybdate-hydrazine sulfate and heating to obtain the molybdenum blue.

**Analysis of plant extracts for chlorophylls a and b, using a commercial spectrophotometer, C. L. COMAR.** (Mich. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 11, pp. 877-879, fig. 1).—Absorption coefficients for the chlorophyll components as determined on a commercially available photoelectric spectrophotometer of high accuracy and purity of radiation were successfully applied to the analysis of plant extracts for chlorophylls a and b.

**Determination of methol in oil of peppermint: Acetyl chloride as a reagent, B. E. CHRISTENSEN and L. PENNINGTON.** (Oreg. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, pp. 54-55).—Acetyl chloride was found a quicker and simpler reagent than acetic anhydride for the acetylation. In the method described the oil is treated with the acetyl chloride, the excess of the chloride is then hydrolyzed by adding water, and the total acidity is determined with 0.3 N sodium hydroxide, the chloride content with silver nitrate (0.3 N) as precipitant and potassium chromate solution as indicator. The results obtained in using acetyl chloride were as accurate as those given by the anhydride and the analytical process was much more rapid.

**Determination of citric acid in pure solutions and in milk by the pentabromoacetone method, E. F. DEYSHER and G. E. HOLM.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, pp. 4-7, figs. 2).—The authors discuss losses occasioned by incomplete bromination, volatilization of the pentabromoacetone precipitate varying with the temperature of the wash water, etc., and conclude that "no absolute method can be prescribed for the complete recovery of citric acid as pentabromoacetone under all conditions. The method must be standardized with respect to the conditions and products employed and corrections made for the losses incurred in each case." They describe, however, a procedure by the use of which aliquots of solutions containing from 0.10 to 0.30 gm. of citric acid gave results that were consistently within  $\pm 0.50$  percent of the theoretical values. When the quantity of citric acid was less than 0.10 gm. the percentage recoveries were slightly less than the value given, and the results were not so consistent as those obtained with the use of larger amounts.

**Colorimetric determination of phenothiazine, H. L. CUPPLES.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 1, p. 53).—In relatively high concentrations of phenothiazine the red color normally produced on adding bromine to the alcoholic solution may be replaced in part by a green compound interfering with the colorimetric determination. The experimentally controllable factors found to favor the formation of the normal red color were quick addition of the bromine water with rapid stirring, addition of the phenothiazine solution to an excess of bromine water, and having the solutions warm (60° C.) when developing the color. When the solution contained plant extractives, it was necessary to allow some time for bromination and to make sure that bromine was present in excess. A suitable determinative procedure is described.

**Estimation of haemoglobin by the alkaline haematin method, J. W. CLEGG and E. J. KING** (*Brit. Med. Jour.*, No. 4263 (1942), pp. 329-333, figs. 2).—Details of methods for the estimation of total hemoglobin, using hemin as a standard, are given, together with instructions for the preparation of standard solutions equivalent to 100 percent of the Haldane, Sahli, and Haden scales. The alkaline hematin method was found to give excellent results and to permit a quicker and more reliable determination than other methods in routine work.

**Relation of chemical analyses of liver to its vitamin A potency, G. S. FRAPS, A. R. KEMMERER, and R. TREICHLER.** (Tex. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 2, pp. 529-532).—Extracts of the livers were pre-

pared by saponifying the tissue with alcoholic KOH, extracting with ether, removing the ether from the extract in vacuo, taking up the residue in 95 percent alcohol, and filtering off the solids which separated upon standing for 2 hr. in an ice-salt mixture. The filtrate obtained was used for spectroanalysis and for biological assay. The spectrovitamin A was determined by a method previously described (E. S. R., 79, p. 100), correction being made for absorption of light by carotenoids, and with the use of the extinction coefficient 1,600. In the bio-assay the growth of rats on various dilutions (made with Wesson oil) of the filtrate was compared with growth on standard carotene solutions by a modified U. S. P. method for vitamin A potency. Of the 18 livers (beef, calf, pork, and lamb) analyzed, 12 contained 45 p. p. m. or more of spectrovitamin A, and the others 44 p. p. m. or less. The livers containing 45 p. p. m. or more assayed approximately 5 U. S. P. units per microgram of spectrovitamin A. For these, biological potency in International Units can be calculated by the equation  $Iu=5.0 S+1.7 C$ , where  $Iu$  is the number of International Units per gram,  $S$  is the spectrovitamin A in parts per million, as found by use of the extinction coefficient 1,600, and  $C$  is carotene in parts per million. For the livers containing less than 45 p. p. m., the factor to be used for multiplying the spectrovitamin A is probably lower, but the results did not show definitely where the line should be drawn. The tentative equation suggested is  $Iu=1.5 S+1.7 C$ .

**A polarographic characterization of nicotinic acid and related compounds.**—I, Pyridine and nicotinic acid, P. C. TOMPKINS and C. L. A. SCHMIDT (*Jour. Biol. Chem.*, 143 (1942), No. 3, pp. 643-653, figs. 3).—The authors find that use of the polarograph cannot be recommended for the analysis of pyridine. If the attempt be made to determine pyridine polarographically, heavily buffered solutions (at least 0.1 N) should be used. Sodium or potassium phosphate buffers in the pH range 6-8 proved most suitable. The polarograph may be used for the determination of nicotinic acid, but owing to the extraordinary effect of pH and buffer capacity on the diffusion current constant, extreme care must be used in its application. The  $H^+$  at the electrode surface must be maintained constant at all times during a determination. The best current-concentration values were obtained in acid solutions. Although good waves could be obtained in sodium acetate, citrate, and bicarbonate solutions, the precision was not sufficiently high to warrant use for quantitative determinations. Various numerical data and observations concerning the behavior of the two compounds in electrolysis in a dropping mercury electrode apparatus are recorded.

**Nicotinic acid content of cereals and cereal products: Microbiological method of assay,** J. S. ANDREWS, II. M. BOYD, and W. A. GORTNER (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 8, pp. 663-666, fig. 1).—Nicotinic acid values obtained for cereals and cereal products by the microbiological method of Snell and Wright (E. S. R., 87, p. 12) varied widely, depending upon the type of extraction employed. Water and dilute acids were comparable extraction media, and alkali and stronger acids were also comparable but gave values about twice as high as the former extraction media. This difference was attributed either to the formation of growth-stimulating substances by the latter solvents or to the liberation of active nicotinic acid compounds by hydrolysis of a less active or inactive precursor. Recovery experiments were quantitative regardless of the type of extraction, thus indicating that growth-promoting substances were not formed, since these would be expected to result in variable recoveries. Lengthening of the growth period in the assay procedure resulted in no increase in values, this also indicating that no stimulators were present.

On the other hand, results of dialysis of aqueous extracts of whole-wheat flour against water by means of cellophane membranes suggested that some hydrolyzable factor with slower diffusion rate was present along with "free" nicotinic acid compounds. It is pointed out that if this is true the choice of extraction procedure required for evaluating cereals would depend on the nutritional availability of the activity liberated by hydrolysis. The distribution of nicotinic acid in a complete set of fractions separated in the commercial milling of wheat was determined by microbiological assay of aqueous and alkaline extracts. Wheat germ, unlike bran and endosperm, did not exhibit increased activity on alkaline hydrolysis; in this respect it resembled yeast and animal tissues. This suggested the possibility of a more readily available form of nicotinic acid activity in biologically active tissues than in storage tissues where hydrolysis is required to liberate complete activity. The distribution of nicotinic acid activity in the various milling fractions differed from that of thiamin and riboflavin. Concentration of nicotinic acid was greatest in the bran.

**Extraction and assay of nicotinic acid from animal and plant tissues: Comparison of methods.** V. H. CHELDELIN and R. R. WILLIAMS (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 8, pp. 671-675).—"At the present time some 25 methods or modifications of methods for the determination of nicotinic acid have appeared in the literature, and several points of controversy exist as to what experimental steps are to be preferred. The present paper is a report of progress with various aspects of this problem as applied to a number of natural substances." The results of the study are summarized as follows:

"Digestion of foodstuffs with takadiastase and papain appears to liberate nicotinic acid completely from a variety of materials. Enzymatic digestion or acid or alkaline extraction gives the same values for nicotinic acid content of meats and milk. Extraction of cereals with acid or alkali, or similar treatment of clear cereal extracts, gives higher nicotinic acid values than enzymatic liberation alone. The increases caused by acid treatment of cereals or cereal extracts are apparently due to the presence in cereals of some substances other than trigonelline which is convertible to nicotinic acid. The increases due to alkaline treatment of cereals or cereal extracts are apparently largely due to the conversion of the substance mentioned [by Dann and Handler (*E. S. R.*, 87, p. 14)], but perhaps partly to conversion of trigonelline into nicotinic acid. That the biologically active substance formed by hydrolysis of the hypothetical precursor is actually nicotinic acid is indicated by consonant determinations of it by both microbiological and chemical methods, provided in the latter case preformed color is removed prior to coupling with metol. Whether the hypothetical precursor substance has antipellagric value is unknown."

**Report on riboflavin.** A. R. KEMMERER. (Tex. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 25 (1942), No. 2, pp. 459-464).—This report of the associate referee on riboflavin deals with an extension of collaborative work (*E. S. R.*, 86, p. 152) in the application of the fluorometric and the microbiological methods in the determination of riboflavin in dehydrated alfalfa meal, whole-wheat flour, and white flour. It appeared that the methods were satisfactory for alfalfa meal, a substance rich in riboflavin, but that both methods were in need of further improvement for satisfactory application to wheat flours and perhaps other cereals. It is recommended that these two methods, tentatively adopted in 1940 for the determination of riboflavin in yeast and dried skim milk, be adopted also for alfalfa. The microbiological method was also recommended for tentative adoption for whole-wheat flour and white flour because of the need for a method for this type of product. It is further recommended "that in the microbiological

method the effect of reducing the number of levels of the test material and standard and increasing the number of tubes on each level be studied; that studies on the microbiological method be continued in order to eliminate the effect of materials that may enhance or inhibit the bacteria and to further improve it; that fluorometric methods be further studied."

**Effect of light on riboflavin solutions:** **Effect of sunlight on reduced and unreduced solutions,** G. M. O'MALLEY and C. W. SIEVERT (*Indus. and Engin. Chem.*, 34 (1942), No. 9, pp. 1117-1118).—Two extracts of defatted milk solids and one solution of synthetic riboflavin, each prepared in 2 percent acetic acid and adjusted to pH 4.5 with sodium acetate, were used in these tests employing suitably diluted aliquots, some of which were reduced with hydrosulfite solution according to the method of Hodson and Norris (*E. S. R.*, 83, p. 151). Reduced and unreduced extracts were exposed for 30 min. to sunlight shining through a laboratory window. After exposure, the solutions in which the riboflavin had been reduced were vigorously shaken with access to air to reoxidize the riboflavin. Results of analyses of reduced and unreduced solutions, both before and after exposure to sunlight, showed that about 90 percent of the riboflavin in the unreduced solutions was destroyed by the exposure to sunlight, but that the destruction was cut to a comparatively small figure by reducing the solution with hydrosulfite before exposure. Reduction of the riboflavin solution by the unstable hydrosulfite did not protect the solution when heat was applied, since the heat drove off the volatile reducing agent, and the riboflavin, reoxidized by the air, was destroyed upon exposure to the sunlight.

**Growth stimulants in the microbiological assay for riboflavin and pantothenic acid,** J. C. BAUERNFEIND, A. L. SOTTER, and C. S. BORUFF (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 8, pp. 666-671, figs. 2).—The microbiological assay procedure employed for the determination of riboflavin was that of Snell and Strong (*E. S. R.*, 82, p. 587) and for pantothenic acid that of Pennington et al. (*E. S. R.*, 85, p. 442) with slight modifications. *Lactobacillus casei* was used as the test organism, its growth response being determined by titer of the lactic acid produced after a 72-hr. incubation period. The extract was prepared by autoclaving from 0.5 to 1.0 gm. of the sample with from 25 to 35 cc. of water for 15 min. at 15 lb. pressure, cooling, and twice repeating the procedure with the residue separated from the supernatant fluid after centrifuging. The final residue was resuspended in distilled water, made to volume, and an aliquot was mixed with a corresponding aliquot of the clarified extract. The results of the riboflavin assay of the clarified water extract and of the water extract with solids suspended were in good agreement in the case of dried skim milk, alfalfa leaf meal, and one sample of liver meal. Higher riboflavin values were obtained on meat scrap, fish meal, distillers' dried solubles, and a second sample of liver meal, by assay of the extracts with solids suspended than by assay of the clarified extracts. The extracted residues added to the basal medium produced no significant increase in growth over that of the basal medium, indicating that the riboflavin had been completely extracted by the extraction procedure. In the presence of a suboptimum amount of synthetic riboflavin (0.10  $\mu$ g. per tube) certain of the extracts, however, did exert a growth-promoting effect apparently due to the presence of some growth-stimulating substance. Photolyzed aqueous suspensions of certain of the foodstuffs and a number of organic compounds tested also exerted a stimulating action in the presence of suboptimum amounts of riboflavin. Several of the compounds were likewise found to exert this growth-stimulating effect on the micro-organism in the presence of suboptimum amounts of pantothenic acid. It is emphasized that this stimulating effect, when detected, may be avoided by (1) the use of clarified extracts, (2) preliminary extraction of the sample with a lipid solvent,

or (3) inclusion of photolyzed extracts of the product in the riboflavin assay medium or by an alkaline- or acid-treated extract of the product in the pantothenic acid assay medium.

**A simple method for the clinical estimation of ascorbic acid in whole blood,** J. DEENY, E. T. MURDOCK, and J. J. ROGAN (*Biochem. Jour.*, **36** (1942), No. 3-4, pp. 271-272).—The method, described as to reagents, procedure, and calculation, is based on the fact that saturation of whole blood with CO prevents the oxidation of ascorbic acid when blood is hemolyzed. An advantage of the method is that it requires only 2 cc. of blood.

**An improved photometric method for ascorbic acid,** C. CARRUTHERS (*Indus. and Engin. Chem., Analyt. Ed.*, **14** (1942), No. 10, pp. 826-828).—The improved microphotometric method described for ascorbic acid determination was based upon the difference in transmission of buffered 2,6-dichlorophenolindophenol before and after reduction. Reduction was carried out at pH 2.5-2.7 and transmission 6.5-6.6. To inhibit the interference due to other reducing substances, such as glutathione and cysteine, mercuric chloride was added to the blue dye solution. Frequent restandardization was unnecessary, and changes in the ascorbic acid equivalency could be read directly from the transmittance-concentration curve.

**Use of toes rather than tibiae in A. O. A. C. chick method of vitamin D determination,** F. D. BAIRD and M. J. MACMILLAN (*Jour. Assoc. Off. Agr. Chem.*, **25** (1942), No. 2, pp. 518-524, fig. 1).—Data were obtained in the course of routine A. O. A. C. chick tests, using middle or inside toes, severed at the middle joint and used without cleaning away the covering tissues or removing the nail. The results, presented and discussed, showed that the percentage of ash of middle toes of chicks is a satisfactory criterion for the interpretation of results by this test, and can be used as well as values for tibiae ash in estimating the vitamin D potency of assay oils by the A. O. A. C. method. "The use of toes rather than tibiae eliminates the labor and time involved in removing the tibiae from the chick and cleaning them of all adhering flesh, and it also eliminates the human error in removing inadequate amounts of flesh from some of the tibiae. In the vitamin D determination the use of toes makes possible the carrying out of the test without sacrificing the chick. Furthermore, it could provide several composite samples, in addition to the tibiae, for ashing from any assay group and also of following the course of calcification in the same chicks over varying periods of time."

**Pectin in war-time has many uses: An important outlet for waste apple pomace,** Z. I. KERTESZ (*Farm Res. [New York State Sta.]*, **9** (1943), No. 1, pp. 1, 3).—The author summarizes, in part, the numerous uses of pectin for food, medicinal, and other purposes, and points out that in 1941 the elder and apple juice producers dried for pectin manufacture less than 10 percent of the apple pomace which was available as a byproduct. The rest of the pomace was practically discarded. The utilization, to whatever extent shortages in equipment, materials, and skilled labor will permit, of this wasted source of pectin would help to meet the increased wartime demand.

## AGRICULTURAL METEOROLOGY

**Basic principles of weather forecasting,** V. P. STARR (*New York and London: Harper & Bros.*, [1942], pp. XXVI+299, [pl. 1], figs. 125).—The particular features which the author desires to bring to the fore in this textbook are "(1) the statement of certain forecasting principles which are now coming into use, and the manner of their application; (2) the introduction of more systematic procedures in actual forecasting; (3) the advantage of constructing prognos-

tic charts for both the surface weather conditions and for the condition in the free atmosphere; (4) the introduction into daily forecasting of checking devices to insure the mutual consistency of certain features of the expected developments."

**Meteorology** (8. *Amer. Sci. Cong., Washington, 1940, Proc., vol. 7, pp. 291-446, pls. 4, figs. 38*).—In 29 contributions (abstracts or full papers in English or Spanish) by various authors, different phases of meteorological conditions and studies in North and South American countries are presented.

**Evaporation from lakes and reservoirs: A study based on fifty years'** [U. S.] **Weather Bureau records, A. F. MEYER** (*St. Paul: Minn. Resources Comm., 1942, pp. 111+56, [pls. 91], figs. [11]*).—The monthly and annual evaporation from lakes and reservoirs in the United States, as determined in this study, is presented in map, graphic, and tabular forms for use in agriculture and forestry, for convenience in the design, construction, operation, and maintenance of various types of waterworks, and for use in further meteorologic and hydrologic studies.

**Characteristics of heavy rainfall in New Mexico and Arizona, L. B. LEOPOLD** (*Amer. Soc. Civ. Engin. Proc., 69 (1943), No. 2, pp. 205-234, figs. 5*).—Seasonal differences in storm types are characteristic of New Mexico and Arizona. Summer storms are ordinarily of small areal extent and typically of high intensity rainfall in a well-defined pattern with relation to time; winter storms cover large areas and are usually of low intensity. Results of frequency analyses of one-day rainfalls are here presented for all stations in the two States with records exceeding 15 yr. The relation of rainfall frequency to geographic position and topographic relief are discussed.

**1942 driest year in 54-year record at State College, R. WOODBURN** (*Miss. Farm Res. [Mississippi Sta.], 6 (1943), No. 1, pp. 1, 7, figs. 2*).—The 1942 rainfall by months as compared with the 54-yr. average and fluctuations in rainfall from year to year for 3 typical months are tabulated and discussed.

**Hydrologic studies at the South Fork Palouse River Demonstration Project, SCS-Wash-1, Pullman, Washington: Compilation of rainfall, run-off and soil loss from the South Fork Palouse River, Fourmile Creek, and Missouri Flat Creek, 1934-40, W. D. POTTER and S. K. LOVE** (*U. S. Dept. Agr., Soil Conserv. Serv., 1942, SCS-TP-47, pp. [280], pls. 17*).

**Hydrologic studies at the Coon Creek Demonstration Project SCS-Wis-1, Coon Valley, Wisconsin: Compilation of rainfall, run-off, and soil loss from the Little La Crosse River and Coon Creek Watersheds, 1934-40, W. D. POTTER and S. K. LOVE** (*U. S. Dept. Agr., Soil Conserv. Serv., 1942, SCS-TP-46, pp. [308], pls. 36*).

**Snow surveys and irrigation water forecasts for the Colorado River Drainage Basin, February 1, 1943** (*U. S. Dept. Agr., Soil Conserv. Serv., and Colorado Sta., 1943, pp. [1]+6*).

**Snow surveys and irrigation water forecasts for the Missouri and Arkansas Drainage Basins, February 1, 1943** (*U. S. Dept. Agr., Soil Conserv. Serv., and Colorado Sta., 1943, pp. [1]+9*).

**Snow surveys and irrigation water forecasts for Oregon as of February 1 and March 1, 1943** (*U. S. Dept. Agr., Soil Conserv. Serv., and Oregon Sta., 1943, Feb., pp. [1]+16, pls. 2; Mar., pp. [1]+13, pls. 2*).

**Snow surveys and irrigation water forecasts for the Rio Grande Drainage Basin, February 1, 1943** (*U. S. Dept. Agr., Soil Conserv. Serv., and Colorado Sta., 1943, pp. [1]+3*).

**Perennial snow and glaciers, J. E. CHURCH.** (*Nev. Expt. Sta. et al.). (Sci. Mo., 56 (1943), No. 3, pp. 211-231, figs. 17*).

## SOILS—FERTILIZERS

[**Soil investigations by the Arkansas Station**] (*Arkansas Sta. Bul.* 428 (1942), pp. 15-16).—Factors affecting the availability and efficiency of fertilizers are discussed by J. R. Cooper.

[**Soil investigations by the Oklahoma Station**] (*Oklahoma Sta. Bion. Rpt.* 1941-42, pt. 1, pp. 6, 16-17, 18, 19, figs. 3).—Investigations are briefly reviewed on the value of a livestock system of farming for maintaining soil fertility and the effect of rainfall on soil crust formation and suggestions on cultivation for obtaining the best results under conditions of soil crust.

[**Physical land conditions in Chariton County, Missouri**, D. C. MAXWELL (Coop. Mo. Expt. Sta.). (*U. S. Dept. Agr., Soil Conserv. Serv., Phys. Land Survey No. 25* (1942), pp. 56, figs. 13, maps [92]).—Results of a detailed soil and erosion survey.

[**Soil-moisture conditions and phenomena in frozen soils**, A. B. C. ANDERSON, J. E. FLETCHER, and N. E. EDLEFSEN. (Univ. Calif.). (*Amer. Geophys. Union Trans.*, 23 (1942), pt. 2, pp. 356-364, figs. 4).—A basic treatment of the thermodynamic theory involved in the interpretation of soil-moisture phenomena in frozen soils.

[**Determination of the losses of moisture by evaporation from soils in a watershed-area**, A. H. HENDRICKSON. (Univ. Calif.). (*Amer. Geophys. Union Trans.*, 23 (1942), pt. 2, pp. 471-474).—A discussion of methods and factors involved in determining the moisture evaporated from watershed areas.

[**Investigations in erosion control and reclamation of eroded land at the Red Plains Conservation Experiment Station, Guthrie, Okla., 1930-40**, H. A. DANIEL, H. M. ELWELL, and M. B. COX. (Coop. Okla. Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul.* 837 (1943), pp. 94, figs. [48]).—The first of a series of reports intended to cover the first decade of investigational work at the 10 original soil erosion experiment stations. Results of experiments in methods of erosion control are given for plats of various sizes, individual terraces, and terraced and natural watersheds under different conditions of vegetative cover, cultivation, cropping system, or terrace design, and the comparative effectiveness of these conditions was determined by measured soil and water losses, crop yields, and observations. The investigational results are interpreted in relation to their application to the Red Plains area. Detailed data for the various conditions are presented in tabular form in the appendix.

[**Strip cropping for war production**, H. E. TOWER and H. H. GARDNER (*U. S. Dept. Agr., Farmers' Bul.* 1919 (1943), pp. 11+46, figs. 36).—Strip cropping methods are described and illustrated by four regions in the United States—The Northeastern and North Central States, the Southeastern and West Gulf States, the Great Plains, and the far West. This publication supersedes Farmers' Bulletin 1776 (E. S. R., 77, p. 864).

[**The farmer and his soil have volunteered**, C. E. MILLAR (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 199-203).—Such important points in soil management as proper tillage, use of manure and fertilizers, what crops to fertilize, use of green-manure crops, and the value of lime are discussed.

[**Soil fertility level as it influences plant nutrient composition and consumption**, R. E. LUCAS, G. D. SCARSETH, and D. H. SIELING (*Indiana Sta. Bul.* 468 (1942), pp. 43, figs. 7).—Nitrogen, phosphate, potash, magnesium, and calcium were determined for corn, wheat, oats, alsike and red clover, soybeans, timothy, and lespedeza grown on long-time soil fertility plats located on Crosby, Bedford, and Clermont silt loams for 3 consecutive years. Detailed data on the chemical composition of the crops grown are given in the appendix.

The data show that for the long-time fertility plats about 70 percent of the added phosphorus is recovered by the crops in a 4-yr. rotation of wheat, hay, corn, and soybeans on limed plats of Clermont and Bedford silt loam soils, while on the unlimed plat in both soils only about 50 percent of the phosphate is recovered. Unfertilized Crosby soil contributed about 20 lb. of phosphate per acre annually to the crop. The average annual amount of potash contributed to crops on unfertilized Bedford, Clermont, and Crosby silt loam was around 20, 25, and 30 lb. per acre, respectively. After about 20 yr. of treatment, differences in the composition of the soil with respect to phosphate and potash were not great.

The authors point out that soil series, soil treatments, and seasons influence greatly the percentage of plant nutrients in farm crops, and that straw and stover vary more in composition than the grain and should be used when determining plant-nutrient levels. They suggest that a selective translocation of plant nutrients, particularly at maturity, accounts for the even composition of the grain.

**Chlorpicrin as a factor in the mobilization of soil nutrients**, A. M. SCHCHEPETIL'NIKOVA and V. CHEREMISOVA (*Larvacide Log*, 5 (1942), No. 2, pp. 32-49, figs. 12).—A translation from the Russian.

**Effect of soil and peat admixtures on the growth of plants in quartz sand**, P. L. GILE and I. C. FEUSTEL. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 2, pp. 49-65).—Additional data (E. S. R., S2, p. 595) are presented on the effect of soil and peat mixtures with quartz sand in an attempt to explain the beneficial response previously obtained from mixtures of pure quartz and soil. The beneficial effect of a soil admixture with quartz sand is reported as being due to the buffer capacity of the soil and the iron provided by the soil. The authors also point out the importance of determining the reaction in the immediate vicinity of the growing root instead of in the entire growth medium.

**Soil tests and soil fertility discussed: 'Salvage manure' is war-vital slogan now**, R. GARDNER (*Colo. Farm Bul. [Colorado Sta.]*, 5 (1943), No. 1, pp. 17-19).—A popular presentation of factors to be considered in obtaining the maximum benefit from fertilizers and manures for increased production. Chemical soil tests are discussed in relation to obtaining more efficient use of fertilizers.

**Utilization of fertilizers during 1943**, W. B. ANDREWS (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, pp. 1, 8).—The author discusses the shortage of nitrogen for farm production because of the demands for war purposes and emphasizes the importance of using available nitrogen so that it will contribute most to winning the war and to farm profit.

**Nitrogen content of miscellaneous waste materials**, A. L. PRINCE and F. E. BEAR (*New Jersey Stat. Cir.* 450 (1942), pp. 4).—Because of the demands for nitrogen for ammunition, the authors point out the importance of utilizing different natural materials and waste products that have a fertilizer value. As a guide for determining the value of various potential fertilizer materials, average analyses are given on fertilizer constituents in 9 manures, 11 humuslike materials, 15 crop materials, and 15 miscellaneous wastes.

**Chemical composition of sewage sludges, with particular reference to their phosphoric acid contents**, W. RUDOLFS and H. W. GEHM (*New Jersey Stat. Bul.* 699 (1942), pp. 15).—The authors find that the value of various types of sewage sludge as a subgrade fertilizer or soil builder cannot be determined by chemical analyses alone, but must be judged by the results it produces. Sludges are not balanced plant foods but contain major and minor mineral elements, growth-promoting substances, and a varying amount of organic matter.

The average total phosphoric anhydride content of sludge varies with the type of sewage treatment from about 1.5 to 4.6 percent. Digested sludge contains more phosphoric acid than plain settled sludge. Activated and humus tank sludge have greater percentages of phosphoric anhydride than settled sludge, and digested chemical sludge has the highest phosphoric anhydride content. Chemical treatment does not increase the insoluble phosphoric acid. The method of dewatering affects the phosphoric anhydride content of the sludges. Activated and plain settled sludges have higher volatile matter contents and greater moisture-holding capacities than digested sludges.

**Phosphate and lime for pasture**, H. W. BENNETT (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, pp. 1, 7, fig. 1).—This popular article brings out the beneficial effect of moderate applications of phosphorus and small quantities of lime for increasing pasture returns on sandy, silt, or clay soils.

**The influence of neutralizing acid-forming fertilizers with dolomitic limestone on the response of cotton to potash**, J. G. FUTUREL and J. J. SKINNER. (Coop. U. S. D. A.). (*Georgia Sta. Bul.* 223 (1942), pp. 15).—Seven soil types were included in a comparative study of acid- v. non-acid-forming fertilizers, the non-acid-forming fertilizers having been neutralized with dolomitic limestone. The effect of the dolomitic limestone on potash availability was determined with cotton. Fertilizers containing dolomitic limestone gave larger yields of cotton than acid-forming fertilizers on Cecil fine sandy loam, Clarksville gravelly loam, and Norfolk and Appling sandy loam soils. Only a small increase in yield resulted from non-acid-forming fertilizers over acid-forming on Orangeburg, Tifton, and Greenville sandy loams. Using dolomitic limestone to neutralize acid-forming fertilizers resulted in practically the same increase in yield without regard to the potash content of the fertilizer. The authors thus conclude that neutralizing acid-forming fertilizers with dolomitic limestone does not materially affect the crop's response or requirement for potash.

**The pH values and lime-requirements of 20 New Jersey soils**, F. E. BEAR and S. J. TORII (*New Jersey Stat. Cir.* 446 (1942), pp. 15, figs. 2).—Tabular information on pH, lime requirement, and calcium-storing capacity is presented for 20 of the most widely distributed types of soil in New Jersey. Selected soil types were studied to determine soil pH before and after applying lime and at weekly intervals following an application of 4,000 lb. of limestone per acre. The relative effects of equivalent amounts of different liming materials was determined with Dutchess shale loam soil from changes in pH value.

**Inspection of commercial fertilizers**, H. R. KRAYBILL ET AL. (*Indiana Sta. Cir.* 275 (1942), pp. 79, fig. 1).—This publication presents the usual analyses and statistical data on fertilizers as required by the Indiana fertilizer law.

**Inspection of commercial fertilizers and agricultural lime products**, P. H. SMITH ET AL. (*Massachusetts Sta. Control Ser. Bul.* 114 (1942), pp. 48).—This report covers both mixed fertilizers and separate sources of nitrogen compounds, phosphates, and potassium salts, as well as liming materials and gypsum. The 1942 inspection analysis data for each of these products are recorded.

## AGRICULTURAL BOTANY

**Growth of bacteria in an iron-free medium**, W. S. WARING and C. H. WERKMAN. (*Iowa State Col.*). (*Arch. Biochem.*, 1 (1942), No. 2, pp. 303-310, fig. 1).—An Fe-deficient medium is described which produces cells of certain bacterial species very deficient in Fe.

**The cytology of bacteria**, I. M. LEWIS (*Chron. Bot.*, 7 (1942), No. 6, pp. 249-250).—A review of recent work.

**The biochemistry of autotrophic bacteria: The metabolism of Thiobacillus thiooxidans in the absence of oxidizable sulfur,** G. A. LePAGE. (Wis. Expt. Sta.). (*Arch. Biochem.*, 1 (1942), No. 2, pp. 255-262).

**p-Aminobenzoic acid, a growth factor for Acetobacter suboxydans,** J. O. LAMPEN, L. A. UNDERKOFFER, and W. H. PETERSON. (Univ. Wis. and Iowa State Col.). (*Jour. Biol. Chem.*, 146 (1942), No. 1, pp. 277-278).

**Zygosaccharomyces acidifaciens: A new acetifying yeast,** W. J. NICKERSON, JR. (*Mycologia*, 35 (1943), No. 1, pp. 66-78, figs. 4).—*Z. acidifaciens* n. sp., a yeast found in apparently pure culture in domestic red wine turning sour, is described.

**Distribution of antagonistic fungi in nature and their antibiotic action,** S. A. WAKSMAN and E. S. HORNING. (N. J. Expt. Stas.). (*Mycologia*, 35 (1943), No. 1, pp. 47-65, figs. 7).—Preliminary to this systematic survey of antagonistic fungi, methods were developed for their rapid isolation from soils, manures, composts, and other natural substrates. No previous enrichment of the soil with bacteria proved necessary. After first establishing their antagonistic nature on solid media, these fungi were grown in liquid media and their activities further studied. Under the experimental conditions some produced antagonistic substances rapidly; others showed only limited antibiotic activities. The various antagonistic fungi thus isolated and tested were found to belong to a number of distinct taxonomic groups, thus far nine having been recognized. Some of the groups belonging to *Aspergillus* and the green *Penicillium* were particularly active; others, like *Chaetomium* and the *P. luteum* group, had considerable activity; still others, such as species of *Fusarium* and *Cephalosporium*, had very little. One of the most active, the *A. fumigatus* group, was studied in detail, since its strains appeared to differ from all other antagonistic fungi thus far reported. The substance isolated, described, and tentatively designated "fumigacin," possesses antibacterial properties typical of the antibiotic group, viz, it is selective in action. An interesting peculiarity is that it proved more active against *Bacillus mycoides* than against *B. subtilis*, whereas other antibiotic substances tested against these bacteria exhibited the reverse effect. There are 16 references.

**Germination of ergot,** A. B. BOSE (*Cur. Sci. [India]*, 11 (1942), No. 11, p. 439, fig. 1).—Germination of sclerotia of *Claviceps purpurea* on moist sand in Petri dishes is reported, and the possibility of laboratory production of medicinal ergot suggested.

**Palmeiras na Bahia do genero Cocos [Palms of the genus Cocos in Bahia, Brazil],** G. BONDAR (*Inst. Cent. Fomento Econ. Bahia, Bol.* 4 (1939), pp. 19, pls. 12).

**Importancia economica das palmeiras nativas do genero Cocos nas zonas seccas do interior bahiano [Economic importance of palms of the genus Cocos in the dry regions of the interior of Bahia],** G. BONDAR (*Inst. Cent. Fomento Econ. Bahia, Bol.* 5 (1939), pp. 16, pls. 5).

**Palmeiras do genero Cocos e descrição de duas especies novas [Palms of the genus Cocos, with descriptions of two new species],** G. BONDAR (*Inst. Cent. Fomento Econ. Bahia, Bol.* 9 (1941), pp. 53+[1], pls. 13).

**Penão, Cuidoscolus marcgravii Polh.: Novo recurso oleifero da Bahia [A new source of oil in Bahia],** G. BONDAR (*Inst. Cent. Fomento Econ. Bahia, Bol.* 12 (1942), pp. 16, pls. 4).—A contribution on this euphorbiaceous tree of Brazil, including data on its taxonomy and identification, and on the culinary and industrial (drying) possibilities of the oil from its seed.

**Las gramíneas argentinas del género Echinochloa [Argentine grasses of the genus Echinochloa],** R. MARTÍNEZ CROVETTO (*Rev. Argentina Agron.*,

9 (1942), No. 4, pp. 310-342, figs. 8).—A taxonomic study of the six Argentine species and their varieties, with a key.

**The grasses of Nova Scotia**, W. G. DORE and A. E. ROLAND (*Nova Scotian Inst. Sci. Proc.*, 20 (1941-42), No. 4, pp. 177-288, figs. 84).—This is a systematic treatment of the Gramineae, with identification keys and notes on characteristics, nomenclature, and distribution of the 121 species of the Province. Diagrams illustrating the essential parts of the inflorescence and ligule region, and distributional maps, are included for most species.

**A proposed taxonomic change in the tribe Maydeae (family Gramineae)**, R. G. REEVES and P. C. MANGELSDOFF. (*Tex. Expt. Sta. et al.*). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 815-817).—As a result of this study *Zea* and *Euchlaena* are considered congeneric, and two species are transferred from the latter as *Z. mexicana* and *Z. perennis* n. combs. A revised characterization of *Zea* is presented.

**State floras of the United States**, S. F. BLAKE. (U. S. D. A.). (*Chron. Bot.*, 7 (1942), No. 6, pp. 258-261, fig. 1).—This list, annotated and summarized in a map, is extracted from the larger work previously noted (*E. S. R.*, 88, p. 169.)

**Mycorrhizae associated with some Colorado flora**, W. D. THOMAS, JR. (Colo. State Col.). (*Phytopathology*, 33 (1943), No. 2, pp. 144-149, fig. 1).—Through this study of certain members of the Colorado flora (about 116 species in 43 families), their mycorrhizas were classified into four main forms. (1) Ectotrophic forms appeared only on trees and shrubs, with the coralloid type predominating and the ball type occurring exclusively on the Betulaceae. (2) Ectendotrophic mycorrhizas were rare, appearing only on the roots of trees and shrubs. (3) Of the endotrophic forms, the peloton type was found most often and vesicles were also common, whereas arbuscules were rare. Endotrophic mycorrhizas were not observed in roots of trees or shrubs. (4) Pseudomycorrhizas appeared almost exclusively in the Pinaceae. Mycorrhizas were found on both humus and sandy soils. Except for those in the Orchidaceae, they appeared only in gymnosperms and dicotyledons, at elevations of 5,000-11,500 ft., and most abundantly at 7,500-10,500 ft.

**Serological studies of the root-nodule bacteria.**—II, **Strains of *Rhizobium trifolii***, J. M. VINCENT (*Linn. Soc. N. S. Wales, Proc.*, 67 (1942), pt. 1-2, pp. 82-86).—A detailed serological study was made of 6 strains of *R. trifolii*, and tests with these and 32 other strains indicated that, as with *R. meliloti*, wider grouping is possible on a flagellar than on a somatic basis, the latter being more strain-specific. Twelve strains possessed neither of the H antigens postulated, but of these 4 gave O reaction. Eight strains, though reacting with the A type of flagellar antibody, failed to react with any of the sera for O. At least 10, probably 11, groups were recognizable, and of these the one reacting with A, II, was the largest clearly defined. In all, this group contained 10 strains collected from 5 plant species growing in widely separated areas. No relationship was evident between a host species and the serological grouping of the strain isolated from it.

**Vitamin deficiencies of twelve fungi**, W. J. ROBBINS and R. MA (*Arch. Biochem.*, 1 (1942), No. 2, pp. 219-220, fig. 1).—When *Ceratostomella* sp., *C. leptographioides*, *C. paradoxa*, *Chalaropsis thielavioides* (three isolates), *Polyporus versicolor*, *Pholiota adiposa*, *Stereum murrayi*, *Schizophyllum commune*, *Sclerotinia* isolates from *Opuntia* and eggplant, and *Claviceps purpurea* were grown in a basal mineral-dextrose medium plus asparagine and supplemented with thiamine, pyridoxine, and biotin singly and in all combinations, nine showed partial or complete deficiencies for one or more of the vitamins and

three showed no response to any of them but grew better in a malt medium than in the above basal medium.

**Vitamin deficiencies of *Ceratostomella* and related fungi**, W. J. ROBBINS and R. MA (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 835-843, figs. 3).—Of the 13 species of *Ceratostomella* tested with respect to thiamine, pyridoxine, and biotin, 11 suffered from complete or partial deficiencies for one or more of them and 6 grew markedly better in a basal medium supplemented with malt than with the three vitamins.

**On the loss of vitamin B<sub>2</sub> from yeast during dissimilation**, T. J. B. STIER and C. F. MACINTYRE (*Jour. Cell. and Compar. Physiol.*, 20 (1942), No. 3, pp. 385-392, figs. 2).

**Polar and apolar transport of auxin in woody stems**, J. OSERKOWSKY. (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 858-866).—Nonresting woody apple and pear twigs often contain free-diffusible auxin; resting twigs rarely yield it in measurable amounts. In nonresting twigs the movement of such auxin in the direction of the long axis is mostly or entirely polar and basipetal. In resting twigs native auxin externally applied through agar blocks was transported basipetally but no measurable transport could be detected in the opposite direction. With indoleacetic acid similarly applied in varying concentrations, basipetal transport was evident in 26 of 34 tests; significant acropetal transport, in 6 of the 34. Translocation of the acid in sections of resting apple and pear twigs involves two simultaneous processes, polar and apolar transport, the former operating only basipetally and presumably via living cells. The polar transport which operates both basipetally and acropetally is probably a diffusion via cell walls and lumina of dead cells, but this process is modified by "fixation" or destruction of auxin along its diffusion path. Basipetal transport of indoleacetic acid and native auxin in these twigs takes place in both bark and wood. "Available evidence does not indicate that cambium accounts for the bulk of basipetal transport of auxin, if it is involved in it at all."

**Comparative activity of synthetic auxins and derivatives**, G. S. AVERY, JR., J. BERGER, and B. SHALUCHA (*Bot. Gaz.*, 104 (1942), No. 2, pp. 281-287).—The activities of indoleacetic, indolebutyric, naphthaleneacetic, dichlorophenoxyacetic, and naphthoxyacetic acids and certain derivatives were compared on desecded oats coleoptiles (both intact and decapitated). The detailed results are presented.

**The effect of colamine on growth and protoplasmic streaming in *Avena***, B. M. SWEENEY (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 793-797, fig. 7).—As far as known, there is no substance in animals comparable to the plant auxins, but extracts of animal tissues contain substances inhibitory to growth of animal cells in tissue culture. One of these substances, colamine, was found to retard the rate of streaming on 4-day-old oats coleoptiles, but only at very high concentrations (1,000-10,000 mg. per liter). From the further data presented it is concluded that colamine acts by making temporarily unavailable a substance necessary to the action of auxin, possibly a 4-C acid.

**Histological responses of *Vicia faba* to indoleacetic acid**, B. F. PALSER (*Bot. Gaz.*, 104 (1942), No. 2, pp. 243-263, figs. 23).—Histologically, every parenchymatous tissue became active to some extent in the development of the tumor induced, vascularization of derived tissues was somewhat extensive, root induction was uncommon under the conditions imposed, and the occasional polyploid nuclei were somewhat more numerous in the treated stems. Detailed results are described. There are 28 references.

**Auxin content of maize kernels during ontogeny, from plants of varying heterotic vigor**, G. S. AVERY, JR., J. BERGER, and B. SHALUCHA (*Amer. Jour.*

*Bot.*, 29 (1942), No. 9, pp. 765-772, figs. 5).—From Country Gentleman, Golden Cross Bantam, a number of pedigreed inbred and hybrid lines, and also from polyploid corn plants, the kernels were harvested at intervals during their development, free and precursor auxins were extracted by an alkaline hydrolysis method, and the extracts were assayed by the *Avena* technic. At pollination time the total auxin present in corn kernels was extremely small, but immediately after pollination the content increased very rapidly, a peak being reached in 1-3 weeks. From the peak to the dormant stage there was a marked drop in auxin content characteristic of all varieties studied. No relationship was apparent between vegetative vigor of hybrids and amount of auxin stored in their kernels. No fixed relationship was found between the amounts of precursor and free auxin, except that the former always constituted the major portion of the total obtainable at any one time. Corn kernels with sugary endosperm were consistently higher in total auxin than those with starchy endosperm. Exploratory experiments with immature kernels of diploid and tetraploid corn also failed to reveal any relationship between polyploidy and the amount of auxin stored in the kernels.

**Auxin and calines in seedlings from X-rayed seeds**, G. F. SMITH and H. KERSTEN (*Amer. Jour. Bot.*, 29 (1942), No. 9, pp. 785-791, figs. 5).—The detailed results here given of a study of the correlation between X-ray-induced modifications and the conditions of auxin and calines in darkroom-germinated pea seedlings from seeds given X-ray treatments appear to indicate that the general types of X-ray-induced structural modifications thus far described for plants can be explained on the basis of growth-factor destruction or transport inhibition. It is believed there is no evidence to date supporting the view that growth inhibitors are synthesized by X-ray irradiation.

**Growth hormones as related to the setting and development of fruit in *Nicotiana tabacum***, R. M. MUIR (*Amer. Jour. Bot.*, 29 (1942), No. 9, pp. 716-720).—Direct measurements of diffusible growth substances on styles and ovaries showed considerable quantities in portions of a pollinated but very little or none in an unpollinated pistil, the concentration being closely related to the extent of penetration of the pollen tubes into the style and fertilization resulting in the release of large amounts in the ovary. These data are considered in relation to the hypothesis advanced to explain the initiation of fruit development by pollination. Extraction of pollen grains and pollen tubes did not indicate them to be the source of the growth hormones. It is suggested that pollen tubes may secrete an enzyme able to liberate growth substances from inactive combinations in the style and ovary. Growth substances released in the fertilized ovary move downward through the pedicel and prevent abscission of the pistil by inhibiting development of the abscission layer. They are also probably concerned in development of the conducting elements through which food materials move into the growing ovary. There are 19 references.

**Species differences with respect to water absorption at low soil temperatures**, P. J. KRAMER (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 828-832, figs. 2).—Studying collard, cotton, watermelon, sunflower, privet, elm, and red, white, loblolly, and slash pines, absorption was reduced in all, but more in species normally growing in warm soil than in those growing at least part of the year in cold soil. Species differences presumably result chiefly from low temperature effects on the viscosity and permeability of the root protoplasm. Reduction of water absorption from cold soil is of considerable ecological and practical importance, since it often produces winter injury and even affects the growth of greenhouse plants.

**Relative drought resistance of seedlings of dominant prairie grasses,** I. M. MUELLER and J. E. WEAVER. (Univ. Nebr. et al.). (*Ecology*, 23 (1942), No. 4, pp. 387-398, figs. 5).—In mixed plantings of 14 species tested at ordinary summer temperatures only a few plants—all short grasses—survived where drought was most critical. With the results of exposure to both soil and atmospheric drought considered, *Bouteloua gracilis* proved most resistant, other species in decreasing order of resistance being *Buchloe dactyloides*, *Bouteloua hirsuta*, *Sporobolus asper*, *B. curtipendula*, *Stipa comata*, *Andropogon scoparius*, *A. furcatus*, *Panicum virgatum*, *Sorghastrum nutans*, *Stipa spartea*, *Koeleria cristata*, *Elymus canadensis*, and *Agropyron smithii*. In general, species characteristic of uplands or normally occurring westward in mixed prairie were more resistant, and those in lowlands or true prairie less so.

**On diurnal variations in the mineral content of the leaf of the cotton plant,** E. PHILLIS and T. G. MASON (*Ann. Bot. [London]*, n. ser., 6 (1942), No. 23, pp. 437-442, figs. 2).—When samples of leaves were collected over a 96-hr. period and their dry weights, water, and mineral contents determined, well-marked diurnal changes in all these values were found. These results are in harmony with the view that the mineral elements enter the leaf in the wood and (except for Ca) are exported from it into the phloem. Interpretation of the results is complicated by mineral losses caused by dew.

**The use of radioactive phosphorus in translocation studies,** R. N. COLWELL (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 798-807, figs. 9).—Methods described enable the rapid longitudinal movement of the radioactive P to be limited to the phloem and studied by radioautographs and the Geiger counter. Studies on the rate and direction of transport and the localization of radioactive P under various conditions showed that when this indicator is restricted to the phloem its movement is correlated with food movement in the plant. There are 20 references.

**The unautolyzable protein of *Aspergillus sydowi*,** N. BOHONOS, D. W. WOOLLEY, and W. H. PETERSON. (Wis. Expt. Sta.). (*Arch. Biochem.*, 1 (1942), No. 2, pp. 319-324).

**Nicotine synthesis in excised tobacco roots,** R. F. DAWSON. (Univ. Mo.). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 813-815).—In contrast to all other organs, the roots were found to manufacture nicotine in appreciable amounts as growth occurred. The bulk thus produced was not retained within the roots but was excreted into the external medium where it accumulated. This completes the proof (E. S. R., 86, p. 605) for the localization of the nicotine synthetic mechanism in tobacco roots.

**Physiological studies in plant nutrition.—XIII, Experiments with barley on defoliation and shading of the ear in relation to sugar metabolism,** H. K. ARCHBOLD (*Ann. Bot. [London]*, n. ser., 6 (1942), No. 23, pp. 487-531, figs. 12).—In further studies of this general subject (E. S. R., 88, p. 171), ear shading and defoliation of barley grown under partial N deficiency were applied on four occasions at weekly intervals, the first at 60 and the last at 81 days after sowing. The treatments given were (1) defoliation, (2) defoliation plus flag-leaf sheath removal, (3) shading the ear, and (2) and (3) combined. The effects on stems and sheaths were confined to alterations in the sugar level, and there was no break-down of residual dry weight to supply assimilation deficiencies. Sugar levels are, therefore, the simple resultant of production and utilization of assimilate and are not complicated by production of sugar from insoluble reserves. Plants treated at low sugar levels failed to store sugar in the stems normally, but those treated at high sugar levels lost sugar at the normal rate. It is concluded that sugar stored in the stems and sheaths

is a reserve and not available for later conversion to starch in the ear, but it is lost from the stem by respiration and other metabolic processes not involving translocation.

Defoliation alone reduced the number of ears maturing but not the size of ear or grain. Early removal of the flag-leaf sheath reduced grain size, but late removal had no effect. The sugar level in the stem was greatly reduced by defoliation, and it is thus suggested that assimilation by the leaves is the source of stem sugar. Shading the ears reduced ear size but failed to affect the number produced. Stem sugars suffered only a small reduction, so that the shaded ears were able to utilize only a small part of the material which would otherwise have appeared as sugar in the stems. The carbohydrates of the ear are thus entirely supplied by directly assimilated material, translocated immediately from the various organs (calculated proportions given). Limitation of ear size by N shortage is believed to account for the small leaf contribution, the assimilate appearing instead as sugar, and leading to the high levels characteristic of N deficiency. If this is true, then the stems afford more accessible supplies of assimilate than the leaves. There are 22 references.

**Influence of oxygen tension on respiration, fermentation, and growth in wheat and rice,** D. L. TAYLOR (*Amer. Jour. Bot.*, 29 (1942), No. 9, pp. 721-738, figs. 9).—In the absence of  $O_2$ , germination in rice was reduced less than 10 percent below that in air and occurred at more than half the normal rate, but wheat failed to germinate at all. Manometric measurements indicated that when the respiration rate was expressed in terms of  $CO_2$  evolved per milligram of dry weight of embryo per hour, intact rice seedlings had 87 percent as great activity in air as wheat seedlings. However, per seedling in air, the  $CO_2$  output of rice was 48 percent as rapid as that of wheat. Oxygen uptake by both was partially inhibited by sodium azide and  $CO$ , indicating at least a partial dependence on cytochrome oxidase. In absence of  $O_2$ , rice seedlings evolved  $CO_2$  1.5 times as rapidly as in air; wheat, only about 50 percent. It may be concluded that the superiority of rice over wheat in ability to germinate and grow in very low  $O_2$  tensions depends on its possession of a highly functional fermentation system which more than compensates for a respiration system even weaker than that of wheat.

Meyerhof quotients pointed to a strong Pasteur effect in rice and a very weak one in wheat. Calculations indicated that for every hexose molecule used in respiration by rice seedlings, about four hexose molecules that would have been destroyed in the absence of  $O_2$  were preserved as respirable substrate. With reduction in  $O_2$  tension there appeared to be a rapid decrease in rate of total energy liberation, so that under complete anaerobiosis the rate for rice was one-sixth that in air and the rate for wheat one-fifteenth that in air. Under low  $O_2$  concentrations, where rice exhibited greater germination and growth than wheat, it also liberated more energy in fermentation. It is suggested as possible that, in promoting growth, energy released anaerobically in fermentation may be more efficiently used than energy liberated in oxidative respiration.

Using excised parts of wheat and rice seedlings, it was found that 65-85 percent of the total  $CO_2$  output at any  $O_2$  tension was contributed by the embryo. The endosperm in rice made up a larger fraction of the weight of the seed than in wheat, and it accounted for a correspondingly higher percentage of the total  $CO_2$  evolution. Growth studies indicated that rice is more tolerant of alcohol than wheat. Some utilization of alcohol as a substrate for aerobic respiration was noted in both seedlings. Certain implications as to substrate utilization and effects of metabolic products are briefly discussed.

The methods used are described, and detailed results are presented. There are 59 references.

**Photosynthesis and respiration in sugar beet as influenced by the staple element of root nutrition**, G. P. USTENKO (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 32 (1941), No. 9, pp. 658-660*).—When leaves on the plant were wetted with solutions of nutrient salts the photosynthetic rate was in all cases increased, N proving most effective when applied during the period of intensive leaf formation and K when sugar was accumulating most rapidly in the root. Using the same salts, injection of solutions of  $\text{NH}_4\text{NO}_3$  and  $\text{Ca}(\text{H}_2\text{PO}_4)_2$  solutions into severed leaves or immersing the petioles therein favored photosynthesis, whereas KCl caused a considerable reduction. Only in attached leaves did KCl favor photosynthesis; in detached leaves the reduction therein was greater with increase in amount of salt applied. When the other salts were present in sufficient amounts (as in attached leaves), KCl increased the photosynthetic rate. Wherever photosynthesis increased from wetting the leaves with nutrient salt solutions the yields were also augmented, though not in direct proportion.

**Some effects of the drug colchicine on cell division**, J. G. HAWKES (*Jour. Genet., 44 (1942), No. 1, pp. 11-22, pl. 1, figs. 3*).—In onion seedlings the spindle mechanism was inhibited by colchicine during mitosis but recovered its normal function after mild treatment. The only cytological effect was apparently on those stages where the spindle would normally be present. The number of restitution nuclei in a root gave a direct indication of how many cells had divided while under the influence of the drug. Cells which had passed through more than one division under colchicine influence proved incapable of many further divisions, since the resulting plants never possessed more than double the normal number of chromosomes. The division cycle was about twice as long as normal under otherwise similar conditions. The subterminal root swellings are shown to be due to a lack of polarity in the diploid cells behind the root tip. Instead of growing longitudinally the maturing cells do so in all directions, their volumes remaining roughly the same as those of cells in untreated roots. It is also indicated that a similar effect of subterminal root swelling is induced by heteroauxin and that neither colchicine nor heteroauxin can produce such swellings if the root tips are removed.

**Chromosomal effects of low X-ray doses on five-day *Tradescantia* microspores**, L. D. MARINELLI, B. R. NEBEL, N. GILES, and D. R. CHARLES. (N. Y. State Expt. Sta. et al.). (*Amer. Jour. Bot., 29 (1942), No. 10, pp. 866-874*).

**Electron micrographs of protein molecules**, W. M. STANLEY and T. F. ANDERSON (*Jour. Biol. Chem., 146 (1942), No. 1, pp. 25-30, pls. 2*).—Preparations of five proteins and of a mixture of tobacco mosaic virus and silver particles were examined under an electron microscope. The estimated diameters of some of the silver particles were about 15 a. u. Molecules of bushy stunt virus and the hemocyanin of an arachnoid (*Limulus*) appeared to be essentially spherical with diameters of about 26 and 20  $\mu$ , respectively. Micrographs of mollusk hemocyanin (*Busycon* and *Viviparus*) showed particles averaging about 22 and 29  $\mu$ , respectively. From the low contrast of these particles in the electron microscope and consideration of ultracentrifuge data, it is inferred that the molecules of these two hemocyanins are probably platelike in shape. A micrograph of edestin (crystalline protein from certain seeds) exhibited many particles ranging up to about 11  $\mu$  in diameter and an almost complete absence of larger particles. There are 17 references.

**The three-dimensional shapes of undifferentiated cells in the petiole of *Angiophytum***, N. HIGINBOTHAM. (Tex. Expt. Sta.). (*Amer. Jour. Bot.,*

29 (1942), No. 10, pp. 851-858, figs. 16).—The observational and other data presented are discussed in relation to the theory that surface film forces predominate in determining cell shapes.

**Vascular differentiation in the vegetative shoot of *Linum*.**—I, The procambium, K. ESAU. (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 9, pp. 738-747, figs. 29).—This section presents the detailed results of a morphological and cytological study of procambium development in perennial flax. There are 21 references.

**On the development of xylary elements in the first internode of *Avena* in dark and light,** R. H. GOODWIN (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 818-828, figs. 7).—In oats, the rate of formation of spiral and particularly of pitted elements was greatly increased by exposures to visible light, pronounced effects being observed as early as 12 hr. after weak irradiations. The close correlation between light inhibition of elongation of the first internode and formation of pitted xylary elements which are incapable of growth in length is brought out, and the possible role of the xylem as an important cog in the light inhibition mechanism is discussed.

## GENETICS

**Variations in chromosomal association and behavior during meiosis among plants from open-pollinated populations of *Dactylis glomerata*,** W. M. MYERS and H. D. HILL. (U. S. D. A. et al.). (*Bot. Gaz.*, 104 (1942), No. 1, pp. 171-177).

**Linkage relations of the Goldfoil factor for resistance to mildew in barley,** F. N. BRIGGS and E. H. STANFORD. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 1, pp. 1-5).—In a cross between the awned and hulled Goldfoil barley, carrying the Goldfoil factor ( $MI_0$ ) for resistance to mildew, and Nepal 595, which carries the contrasting characters, mildew resistance was found linked with hooded ( $K$ )  $18.77 \pm 2.33$  percent and with  $Bl$  for blue aleurone with a crossover of  $26.31 \pm 5.05$  percent. As Robertson et al. (*E. S. R.*, 67, p. 375) had shown previously,  $K$  and  $Bl$  are linked with a value of  $22.58 \pm 0.82$  percent. These factors have been assigned to linkage group IV. The order suggested is  $Bl, K, MI_0$ . Red stem color in this cross, found due to a single factor  $R_s$ , was linked with hulled ( $N$ ),  $14.50 \pm 1.06$  percent and with a second factor for blue aleurone ( $Bl_1$ ) with a cross-over value of  $9.07 \pm 1.24$  percent. These genes were assigned to linkage group III and the suggested order is  $N, Bl, R_s$ .

**The developmental relationship between shoot apex and growth pattern of leaf blade in diploid maize,** E. C. ABBE, L. F. RANDOLPH, and J. EINSET. (Univ. Minn., U. S. D. A., and Cornell Univ.). (*Amer. Jour. Bot.*, 28 (1941), No. 9, pp. 778-784, figs. 5).

**The effects of translocation on growth in *Zea mays*,** L. M. ROBERTS. (Conn. [New Haven] Expt. Sta. et al.). (*Genetics*, 27 (1942), No. 6, pp. 584-603, figs. 2).—The 13 reciprocal translocations, identified cytologically in an inbred line of Connecticut 20 corn following pollen irradiation with 1,000 r-units, involved all chromosomes except chromosomes 7 and 9. Comparison of homozygous and heterozygous progenies of the 13 translocations in a replicated field test with the normal untreated inbred from which they were derived revealed no conspicuous phenotypic changes. Significant small differences, relatively infrequent, were found by statistical study of several plant characters. Recessive mutations did not adequately account for all the changes found.

**Convergent improvement with four inbred lines of corn, R. P. MURPHY.** (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 2, pp. 138-150).—By convergent improvement, marked gains could be made in the recovered lines in vigor, in resistance to smut and lodging, and in soundness of the ear in instances where the original lines lacked these characters. Most recovered lines yielded significantly higher in crosses to the recurrent parent than the original recurrent parent. Some recovered lines yielded as well as the original  $F_1$  cross when tested in crosses with the nonrecurrent parent. Performances of the recovered lines when crossed to the recurrent and nonrecurrent parents, respectively, were not related. No difference was apparent in the performance of the recovered lines from 2-, 3-, and, in the one instance, the 4-yr. backcrosses. Single crosses between recovered lines which yielded higher than the original  $F_1$  cross could be obtained. Chances of obtaining high-yielding crosses were greatest when recovered parental lines had been high or intermediate in combining ability as measured by their yield in crosses to the nonrecurrent parent.

**Genetics of self-compatibility in *Trifolium repens*, S. S. ATWOOD.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 353-364).—While most white clover plants are relatively self-incompatible, one found in 1938 averaged over 100 seeds per head, and this high seed set was duplicated on clones from this plant by hand-pollination and by bee-pollination. This plant was crossed with a self-incompatible plant, and 14  $F_1$  plants diallely intercrossed and backcrossed to both parents. Two intrasterile, interfertile groups of 5 and 6 plants, respectively, found in this  $F_1$  population were reciprocally compatible with both parents but all relatively self-incompatible. The other 3  $F_1$  plants were cross-compatible with both  $F_1$  groups, with both parents, and with each other, and were also self-compatible. The results were explained by postulating that the original self-compatible parent was heterozygous for a self-compatibility factor ( $S_r$ ), which is a member of the multiple allelic series conditioning self- and cross-incompatibility, and that this factor was transmitted to the 3 self-compatible  $F_1$  plants. See also earlier notes (E. S. R., 80, pp. 26, 174).

**The aid of exploration in potato improvement, H. G. MACMILLAN.** (U. S. D. A.). (*Amer. Potato Jour.*, 19 (1942), No. 12, pp. 255-266).

**Inheritance of growth habit, cotyledon color, and cup-leaf in *Melilotus alba*, E. E. HARTWIG.** (Ill. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 2, pp. 160-166, fig. 1).—Growth habits of F. C. 13074 and of the dwarf-branching segregate of F. P. I. 89911, leafy, short, fine-stemmed types of biennial white sweetclover, were inherited as simple recessives to the common growth type. The respective genes found to determine the dwarf-branching character in these types were designated as  $d_1$  for Alpha,  $d_2$  for F. C. 13074, and  $d_3$  for F. P. I. 89911, and  $d_2$  for the bunch dwarf of Clarke (E. S. R., 65, p. 325). Yellow cotyledon color,  $I$ , behaved as a simple dominant to green cotyledon,  $i$ , but the  $F_1$  cotyledon color usually resembles that of the maternal parent and apparently is affected by environment. Cup-leaf was determined by a single gene,  $c$ , recessive to normal leaf,  $C$ . The genes  $i$ ,  $c$ , and  $d_2$  are inherited independently.

**Inheritance of seed color in biennial white sweet clover, *Melilotus alba*, S. P. SWENSON.** (S. Dak. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 5, pp. 452-459).—Occurrence of normal yellow, pale yellow, pale green, and green seed colors in biennial white sweetclover (E. S. R., 82, p. 180) could be attributed to different combinations of two independent gene pairs.  $C$  is necessary for color production in the seed coat,  $cc$  plants having colorless seed coats.  $Y$  produces yellow and  $y$  green cotyledons, regardless of seed coat color, although

in the presence of *C* the yellow or green color also develops in the seed coat. Seeds with colorless seed coats and yellow cotyledons (*cY*) are pale yellow; those with colorless seed coats and green cotyledons (*cy*) cannot be distinguished from normal green by ordinary visual examination. Normal v. dwarf habit of growth in green  $\times$  pale yellow are differentiated by a single gene pair independent of the two genes for seed color. The heterozygotes were intermediate in growth habit.

**Further studies on interspecific genetic relationships in *Lactuca*, R. C. THOMPSON.** (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 1, pp. 41-48, fig. 1).—A total of 69 crosses was attempted between 8-chromosome species and between species with 8, 9, or 17 chromosomes. Hybrids were obtained in only 8 of the 44 interspecific matings, and of these all were sterile except those from a cross between the 8-chromosome species *L. bourgaci*  $\times$  *L. marschalli*. Further evidence (E. S. R., 86, p. 176) was obtained that the *L. serriola* group, to which the cultivated lettuce belongs, constitutes a compatibility group not closely related to the other groups of lettuce species studied. The successful crossing of certain 8- and 9-chromosome species, although resulting in sterile hybrids, indicated that the 17-chromosome species may have arisen from hybrids of 8- and 9-chromosome parents.

**Diploid-tetraploid periclinal chimeras as bud variants in citrus, H. B. Frost and C. A. Krug.** (Calif. Citrus Expt. Sta. et al.). (*Genetics*, 27 (1942), No. 6, pp. 619-634, figs. 12).—Studies of a bud variant which arose on a hybrid citrus tree (King  $\times$  Dancy) suggested that the variant owed its peculiar characters to the occurrence of somatic chromosome duplication and had produced buds of at least two types of cytological constitution, both of which were periclinal chimeras.

**Chromosome number in the progeny of triploid *Gladiolus*, with special reference to the contribution of the triploid, R. E. Jones and R. Bamford.** (Md. Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 10, pp. 807-813, figs. 12).—The results are presented of chromosome counts on 460 plants obtained from pollination of triploid forms with diploids and tetraploids. The range of the somatic chromosome numbers in the progeny was from 33 to 88.

[**Papers on animal genetics**] (*Genet. Soc. Amer. Rec.*, 11 (1942), pp. 75, 76-77, 78, 79-80, 80-81, 87-89, 92, 95-96).—Brief abstracts are presented of the papers that were to have been presented before the Genetics Society of America at the 1942 meeting in New York: New Extreme Variants in a Selection Experiment, by H. D. Goodale (p. 75); Frequencies of Seven Dominant Genes in Natural Populations of *Platypoecilus maculatus* and Experimental Evidence of a Multiple Allelic Series, by M. Gordon (p. 76); Genetic Constitution of the Mother as a Means of Predetermining the Sex of the Progeny, by J. W. Gowen and R. H. Nelson (p. 76) (Iowa State Col.); A Possible Case of Directed Mutation in the Pigeon, by W. F. Hollander (pp. 76-77); A Critical Test of Strains of Fowls Bred for Resistance to Lymphomatosis, by F. B. Hutt, J. H. Bruckner, R. K. Cole, and R. F. Ball (p. 77) (Cornell Univ.); Heterogeneity in the Lethal Mutation Rate Within a Wild Population of *Drosophila melanogaster*, by P. T. Ives (p. 77); Spleen Transplantation Relationships Among Two Inbred Lines of Mice and Their  $F_1$  Hybrid, by N. Kaliss and T. Robertson (p. 78) (Cornell Univ.); Genetic Resistance to Deficiency of Riboflavin in the Chick, by W. F. Lamoreux and F. B. Hutt (pp. 79-80) (Cornell Univ.); The Failure of Selection to Modify Shank-Growth Ratios of the Domestic Fowl, by I. M. Lerner (pp. 80-81) (Univ. Calif.); A Skeletal Difference Between Reciprocal  $F_1$  Hybrids From a Cross of Two Inbred Strains of Mice, by W. L. Russell and E. L. Green (p. 87) (Ohio State Univ. et al.); A Quantitative Histological Study of

**Genic Effects on Coat Color in the House Mouse**, by E. S. Russell and W. L. Russell (pp. 87-88); **Inheritance of "Atropinesterase," A Blood Enzyme of the Rabbit**, by P. B. Sawin and D. Glick (p. 88); **Differences in the Social Organization of Mice Caused by Differences in Social Behavior (Fighting of Males)**, by J. P. Scott (pp. 88-89); **Marcelled, A New Recessive Mutation Affecting the Coat of the House Mouse**, by A. G. Steinberg and F. C. Fraser (p. 92); and **"Misty," A New Coat Color Dilution in the Mouse, *Mus musculus***, by G. W. Woolley (pp. 95-96).

**Are pedigrees important?** D. G. STEELE. (Univ. Ky.). (*Blood-Horse*, 38 (1942), No. 19, pp. 574-577).—Studies of the two-line pedigrees by the sampling methods of Wright and McPhee (E. S. R., 54, p. 324) of breeding methods and relationship of stake winners and beaten Thoroughbred horses in 1935, 1940, and 1941 showed only minor ancestral differences. The breeding methods followed in the Thoroughbred horse were similar to those found in other classes of farm animals. The importance of performance and ancestors in the first and second generations is emphasized.

**Cross-breeding of chinchillas**, G. M. BRUN (*Amer. Fur Breeder*, 15 (1942), No. 5, pp. 20, 22, 26, fig. 1).—Progress was made in the development of chinchillas of improved quality and vigor by crossing the more hardy type *Brevicaudata*, found at high altitudes, with the *Lanigera* type which was more capricious but showed certain desired qualities and was found at lower altitudes.

**Breeding chickens for meat production**, V. S. ASMUNDSON, and I. M. LERNER (*California Sta. Bul.* 675 (1942), pp. 45, figs. 10).—In this companion to Bulletin 626 (E. S. R., 80, p. 472), the inheritance of meat production characters is reviewed. The efficient breeding program comprises recognition of individuals capable of transmitting superior qualities to their progeny. Special attention is given to literature on market requirements for meat birds, growth rates, and quality of edible meat, cross-breeding, feathering, colors, and sex-linkage in the inheritance of these qualities.

**The role of breeding in the control of fowl paralysis**, F. P. JEFFREY, F. R. BEAUDETTE, and C. B. HUDSON (*New Jersey Stat. Bul.* 696 (1942), pp. 4).—The percentage of paralysis and laying house mortality occurring in a line of Single-Comb White Leghorns selected and inbred for freedom from fowl paralysis was reduced from 33 and 84 percent in 1934 to 3.5 and 27 percent, respectively, in 1940. At the same time in a line selected for a high incidence of paralysis the percentage of paralysis decreased from 29.8 to 10.1 percent, and the laying house mortality from 80 to 41 percent. If the difference in reduction is attributed to breeding, three-fourths of the reduction in incidence must be attributed to other than breeding factors.

**Restitution of the tail in the early chick embryo**, E. ZWILLING. ([Conn.] Storrs Expt. Sta.). (*Jour. Expt. Zool.*, 91 (1942), No. 3, pp. 453-463, figs. 6).—The studies reported have shown the removal of the entire tail anlage from 17- to 27-somite chick embryos to result in the absence of the tail. "When a portion of the undifferentiated tissue of the anlage remains there is a restitution of the tail in a large percentage of the cases. This is probably due to the totipotency of the cells comprising the tail thickening. Deletions of all or part of the primitive streak from 11- to 14-somite embryos may result in tail restitution, probably as a consequence of continued tissue movements. Earlier stages may have this capacity, but the present technic does not allow for a proper demonstration."

**Germ cell studies in the male fox (*Vulpes fulva*)**, D. W. BISHOP (*Anat. Rec.*, 84 (1942), No. 2, pp. 99-115, pls. 4).—The diploid chromosome number in

the silver fox was found to be 32, which included a small Y and larger X chromosome in the  $\delta$ . Study was made of testicular material from 17 1-5-year-old silver foxes, *V. fulva*. Details of the germ cell formation and chromosome behavior are described.

**A study on spermatogenesis in rats**, E. CUTLY (*Amer. Jour. Physiol.*, 137 (1942), No. 3, pp. 521-526, figs. 8).—Three groups of rats hypophysectomized at different ages showed that no spermatozoa developed when the operation was performed before day 29, and many tubules revealed degenerative changes after this age, although some sperm formed. It appeared that testosterone propionate was injurious to gamete formation. In some way the germ cells became detached from the tubular epithelium and were transported to the epididymus where they degenerated. On the other hand, treatment of such animals with pregnant mare serum induced tubular development and sperm formation. When hypophysectomized after 29 days, sperm developed in animals treated with the androgen and the gonadotropins, but with testosterone treatment there was sloughing and degeneration in the seminiferous epithelium and epididymis. Damage from androgen was less when hypophysectomized between 35 and 44 days of age.

**Increase in weight of gonads following injection of single male rat pituitary**, R. P. REECE and E. J. WEATHERBY. (*N. J. Expt. Stas.*). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 218-219).—The ovaries of 24- to 26-day-old rats and the tests of day-old White Leghorn chicks showed average increases of 309 and 62 percent, respectively, following eight divided doses of  $\delta$  rate pituitary over a 4-day period.

**Induction of male copulatory behavior in a hen following administration of male hormone**, A. ZITBIN (*Endocrinology*, 31 (1942), No. 6, p. 690).—Copulatory behavior was induced in a pullet following the implantation of a testosterone pellet. The hen afterward laid eggs at least one of which proved fertile.

**Fetal survival following the injection of Antuitrin-S in pregnant rats and rabbits**, R. M. COCO. (La. State Univ.). (*Amer. Jour. Physiol.*, 137 (1942), No. 1, pp. 143-145).—Injection of pregnant rats and rabbits during late pregnancy with varying doses of Antuitrin-S (40-200 rat units) usually resulted in death of the fetuses in utero or soon after parturition. The ovaries usually contained induced corpora lutea, but these evidently did not reach a threshold level of secretion. The study was based on 86 rats and 16 rabbits injected by methods previously described (*E. S. R.*, 83, p. 758).

**Hormone-induced ovulation in domestic fowl**, R. M. FRAPS and G. M. RILEY. (U. S. D. A.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 253-257).—By the intravenous administration of a luteinizing preparation after pretreatment with pregnant mare serum, multiple ovulations were induced in the hen. Ovulation occurred in 24 of 26 hens 22 hr. after the luteinizing hormone injections, as ascertained by the presence of single-yolked eggs in utero. None of 8 control hens injected only with pregnant mare serum had eggs in their oviducts. On second injection with luteinizing hormones 22 hr. after the first, 7 of the 26 hens showed eggs in utero 24 hr. later. When the group of hens that ovulated were again injected with 20 units of luteinizing hormone 3 days later, 8 eggs were shown to be in utero 24 hr. later. Eggs were not present in utero of those hens not injected with luteinizing hormone, and none showed evidence of previous ovulations. In another experiment all of 16 hens pretreated with pregnant mare serum were caused to ovulate an average of 3.5 times per hen. These hens were pretreated with 6-11 daily doses of 100 rat units of the pregnant mare serum, but when 20 rat units were used only 13 of 16 hens ovulated.

**Effects of a series of steroids on ovulation and reproduction in pigeons,** H. H. DUNHAM and O. RIDDLE (*Physiol. Zool.*, 15 (1942), No. 3, pp. 383-395, pl. 1).—In studies of ovulation in the fowl extending those of Phillips and Warren (*E. S. R.*, 77, p. 770), the action of a series of steroids on ovulation, oviposition, and eggshell formation in the ringdove and common pigeon was investigated. Doses of desoxycorticosterone acetate, ranging from 0.05 to 2.25 mg., injected in 43 ringdoves, and 0.05-0.5 mg. of progesterone in 20 birds, tended to prevent normal ovulations. Controls received sesame oil or propylene glycol, the solvents used without noticeable effect. All steroids injected at 5-36 hr. before ovulation delayed or prevented ovulation, but higher concentrations of oestradiol benzoate, oestrone, dehydroandrosterone, and androsterone were required in over 150 tests.

**Frozen plant juice as the source of a rabbit ovulating factor,** R. BORASKY and J. T. BRADBURY. (U. S. D. A.). (*Amer. Jour. Physiol.*, 137 (1942), No. 3, pp. 637-639, fig. 1).—Oat juice collected at different times during the growing season retained its ovulating potency in the rabbit for at least 21 mo. in the frozen condition. The rabbit was variable in its responsiveness in different seasons, and little response was induced during the late summer.

**Copulatory behavior in prepuberally castrated male rats and its modification by estrogen administration,** F. A. BEACH (*Endocrinology*, 31 (1942), No. 6, pp. 679-683, fig. 1).—The daily administration of oestrogen for 6 days to ♂ rats castrated at 21-23 days of age increased the frequency of responses to receptive ♀s after 100 days. Some copulatory activity was noted prior to the administration of the hormone.

**Male and female mating behavior in prepuberally castrated female rats treated with androgens,** F. A. BEACH (*Endocrinology*, 31 (1942), No. 6, pp. 673-678, figs. 3).—Incomplete masculine responses exhibited by prepuberally castrated ♀ rats were increased 95 percent by the injection of testosterone propionate, and a greater portion of complete copulatory pattern responses was exhibited. No receptive behavior was exhibited by normal ♂s before androgen administration, but after treatment lordosis appeared in 4 rats and/or characteristic ♀ mating responses were exhibited. The study was conducted with 10 ♀ rats castrated at 21-27 days of age and raised in segregation with tests of copulatory responses on alternate days between the ages of 35 and 67 days. Each ♀ received a total of 24 mg. of androgen over a period of 2 weeks.

**Exploratory study of early effects of urinary gonadotropin in prepuberal male rats,** E. Z. BURKHART. (Univ. Ark.). (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 152-153).—Antuitrin-S administered in the form of single or double doses totaling 20 rat units caused an increase in mitotic activity in the ventral prostate and seminal vesicles. Mitotic activity was arrested by colchicine. The single dose was as effective in the 20 rats injected when tested up to 44 hr. after the first injection.

**Presence of estrogenic hormone(s) in testicular material,** B. CUNNINGHAM, J. MAY, and S. GORDON (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 130-132).—Essays of deer testes showed the presence of oestrogens in greater concentrations than were found in bull testes. The assays were conducted with ovariectomized rats.

**The oviduct and egg transport in the albino rat,** R. H. ALDEN (*Anat. Rec.*, 84 (1942), No. 2, pp. 137-169, pls. 4).—The entrance of the egg into the oviduct of the rat is effected primarily by the action of cilia, while further progress is governed by muscular contraction. These conclusions were based on observations by transillumination of oviducts of 30 rats containing artificially introduced material and fertilized and unfertilized ova. The histological changes in the

oviduct with the sex cycles and egg transportation and cilia formation and structure are described.

**A case of extrauterine pregnancy in the rabbit, M.-D. F. NUTTING** (*Anat. Rec.*, 84 (1942), No. 2, pp. 215-219, fig. 1).—A case of extrauterine pregnancy was found in the rabbit with the discovery of a 29-day-old fetus with normal hair growth and another of about half the size. The fetuses were attached with blood supply through the mesentery along the small intestine and the omentum.

**Actions of sex hormones on oestrous cycle and reproduction of the golden hamster, O. PECZENIK** (*Jour. Endocrinol.*, 3 (1942), No. 2, pp. 157-167, pl. 1).—Study of the oestrous cycles and the effects of gonadotropic injections on 76 normal and castrated hamsters showed that typical vaginal smears were produced by moderate or large doses of gonadotropins spread over several days, as well as in the pregnant hamsters and those treated with progesterone. Anterior pituitary gonadotrophin injections inhibited the oestrous cycle, whereas large doses caused sterility. Moderate doses of stilboestrol or chorionic gonadotropin induced ovulation, and pregnancy followed in sterile ♀s which were less than 10 mo. of age. No litters lived more than a few days when the treated ♀s were older.

**The method of growth of the follicle and corpus luteum in the mouse ovary, W. S. BULLOUGH** (*Jour. Endocrinol.*, 3 (1942), No. 2, pp. 150-156, pl. 1, fig. 1).—Further survey of the above data suggests that cells other than the follicle and corpus luteum are affected by the presence of high concentrations of oestrogen in the follicular fluid.

**An androgenic substance in feces from cattle as demonstrated by tests on the chick, G. M. RILEY and J. C. HAMMOND.** (U. S. D. A.) (*Endocrinology*, 31 (1942), No. 6, pp. 653-658).—Comb growth in chicks was stimulated by the inclusion in the ration of 10 percent dried feces from pastured cows and helpers, whereas there was no effect from bull feces or feces from cows not having access to pasture. Growth of the gonads of ♂ and ♀ chicks was retarded by diets containing androgen. Both alcohol and chloroform extracts of the cows' feces had androgenic activity, but when the alcohol concentration was increased to 80 percent it was without effect. A chloroform extract of 1 gm. of dried feces probably had somewhat more androgenic activity than 16 µg. of testosterone acetate. Feces from mature bulls were without effect on comb growth or gonadal development. The study was conducted in three experiments with 6, 8, and 6 lots of 25 chicks each. There were included testosterone acetate additions as well as the extracts of the feces.

**Progesterone effect on pituitary lactogen content and on mammary glands of ovariectomized rats, R. P. REECE and J. A. BIVINS.** (N. J. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 582-584).—The daily subcutaneous administration of progesterone to spayed rates increased the lactogen content of the pituitary through an increase in hormone concentration, but no significant difference from untreated controls was noted in the pituitary weight. When oestrogen was administered separately or with progesterone, there was further increase in the lactogen production and the pituitary weight was increased. The study was based on pituitaries of spayed ♀ rats treated for 10 days with 15 mg. of progesterone or 33γ of oestradiol benzoate, or a combination of the two in comparison with controls. Lactogen was ascertained in bird units (E. S. R., 85, p. 332).

**Effect of estrone on lactogen content in pituitary and blood of male rabbits, J. MEITES and C. W. TURNER.** (Univ. Mo.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 190-193).—The daily injection of ♂ rabbits with 50, 100, and 500 I. U. of estrone caused a considerable increase in

the lactogen in the pituitaries and blood stream but not so much with the higher levels as with the lower levels of injection. A very definite increase of lactogen in the blood stream was associated with increased amounts of lactogen in the pituitary.

**Mammary gland growth in hypophysectomized castrated guinea pigs, E. T. GOMEZ.** (U. S. D. A.). (*Endocrinology*, 31 (1942), No. 6, pp. 613-618, figs. 9).—Growth of the duct system of the mammary gland of hypophysectomized castrated ♂ and ♀ guinea pigs was induced by injecting extracts, or implantations, of 20-50 mg. of fresh anterior hypophyseal gland tissue from adult ♂ and ♀ animals. The extracts were injected over a 10-day period and the minimum effective dose was 20 mg. of the tissue or extracts of this amount. Slight duct growth was induced by lactogenic hormone injections, but it was improved by simultaneous injection with oestrogen. Lactogenic extracts with an alcohol-ether mixture were mammogenically inactive. The studies were conducted with 44 hypophysectomized gonadectomized guinea pigs of both sexes injected with steroid hormones, extracts, or implantations of the anterior hypophyseal gland.

**Lactogenic content of pituitaries of pseudopregnant rabbits, J. MEITES and C. W. TURNER.** (Univ. Mo.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 193-194).—The normal mature rabbit, the pseudopregnant rabbit, and the pregnant rabbit all were found to contain about 10 R.-T. units of lactogen per pituitary gland. The study was conducted by methods previously described by Reece and Turner (*E. S. R.*, 78, p. 323).

**Assay of adrenals for lactogenic hormone, V. HURST, J. MEITES, and C. W. TURNER.** (Univ. Mo.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 592-594).—Assays for lactogen by the intradermal (micro) pigeon crop test (*E. S. R.*, 85, p. 607) showed that two commercial adrenal cortical extracts, whole untreated rabbit adrenal glands, and isoelectric precipitates of beef, hog, and rabbit adrenals did not cause the production of significant amounts of lactogen in the pituitaries. The study was conducted with 105 treated pigeons in groups of about 10 with each extract.

**Effect of adrenalectomy on the lactogenic hormone and initiation of lactation, J. MEITES, J. J. TRENTIN, and C. W. TURNER.** (Mo. Expt. Sta.). (*Endocrinology*, 31 (1942), No. 6, pp. 607-612).—In 33 ♀ rats, adrenalectomy reduced the lactogen content of the pituitaries about 27 percent on a body weight basis. When 1,000 I. U. of oestrone were administered to 10 normal rats, there was an increase in the lactogen production of the pituitaries of 216.9 percent of normals, and 104.5 percent increase in the lactogen production by adrenalectomized rats to which oestrone was administered. The lactogen content of the pituitaries of rats adrenalectomized during the last week of pregnancy did not differ from normal, but lactation was at a lower rate after parturition and about half of the young were dead 2 days later though milk was present in the stomachs. It appeared that removal of the adrenals was followed by decreased secretion of pituitary gonadotropins, causing reduced oestrogen secretion and thus reduced lactogen production by the anterior pituitary. The experimental results were obtained with 111 albino and hooded ♀ rats averaging 188 gm. in body weight with autopsy about 7 days later. Lactogen assays were made by the pigeon crop method (*E. S. R.*, 78, p. 324). Similar results were obtained with 29 ♂ and ♀ guinea pigs.

**Lactogenic hormone prolongs the time during which deciduomata may be induced in lactating rats, R. LYON.** (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 156-157).—Evidence of corpus luteum stimulation by the lactogenic hormone in 13 of 15 rats from the twentieth to twenty-fourth postpartum day is presented. Microscopical deciduomata, together with

robust appearing corpora lutea, were present after four daily treatments with lactogenic hormone.

**Effect of thyroidectomy, castration, and replacement therapy on thymus, lymph nodes, spleen in male rats,** W. O. REINHARDT and P. WAINMAN. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 2, pp. 257-260).—An interrelationship between the thyroid, thymus, spleen, lymph nodes, and the testes of rats was demonstrated in 4 main groups of 60-day-old ♂s consisting of unoperated normals, castrates, thyroidectomized, and castrated thyroidectomized animals. Subgroups of about 10 each were given thyroxin or testosterone propionate, or kept as controls without further treatment. In general, castration alone or in combination with thyroxin caused definite increases in the weights of the thymus, lymph nodes, and spleen. Thyroidectomy alone reduced the weights of the thymus and spleen to a small extent. Testosterone propionate administration prevented the increases in weights following castration. Histological study showed the tissues to be graded in the order of decreasing responsiveness as thymus, cervical lymph nodes, mesenteric lymph nodes, and spleen. Changes in the thymus were correlated with changes in the other tissues.

### FIELD CROPS

[Field crops research in wartime in Arkansas]. (Partly coop. U. S. D. A.). (*Arkansas Sta. Bul.* 428 (1942), pp. 6-12, 46-47).—Investigations with field crops and related lines (E. S. R., 88, p. 40) making useful contributions during the current emergency and reported on briefly by C. K. McClelland, J. O. Dockins, D. B. Shank, and R. P. Bartholomew included variety experiments with corn and hybrids, oats, barley, wheat, rice, peanuts, and soybeans for seed and hay; relative performance of corn varieties and hybrids on soils of different levels of fertility; use of barley to replace all or part of the corn used for feed in Arkansas; breeding work with oats, rice, soybeans, and longer staple cotton adapted to mechanical picking; spacing tests with peanuts; value of green manure to replace N fertilizers and effects on yield of corn, rice, and cotton; relative merits of crop rotation and superphosphate on yields of oats, wheat, clover, and corn; and factors affecting adaptation of soybean production on cotton farms for oil mills.

**Michigan crops for 1943,** H. C. RATHER (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 203-208, figs. 3).—Special considerations mentioned as confronting Michigan farmers in 1943 include varieties of corn, oats, barley, field beans, soybeans, and potatoes; fertility needs and cultural practices for beans, soybeans, and forage crops; potato fertilizers; and labor needs for potatoes and sugar beets.

[Field crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, pp. 2-3, 6, 7).—Articles of current interest are entitled More Peanuts Needed—Survey Reveals Cause Low Yields, Means of Increasing, by F. J. Welch (pp. 1, 7); and Yields of Corn Hybrids and Varieties at Hill Stations, by W. H. Freeman (pp. 2-3, 6).

[Field crops research in Oklahoma, 1940-42]. (Partly coop. U. S. D. A. et al.). (*Oklahoma Sta. Bien. Rpt. 1941-42, pt. 1*, pp. 13-16, 18, 19-25, 40, 41-42, 87, figs. 8).—Field crops work (E. S. R., 84, p. 752) during the above period, reported on briefly, included variety tests with cotton (E. S. R., 87, p. 369), corn and hybrids, wheat, barley, oats, grain sorghums, sorgo, potatoes, sweetpotatoes, and miscellaneous grasses; breeding work with cotton, wheat, oats, sorghum, and sweetpotatoes; improvement of the quality of Oklahoma wheat

(E. S. R., 87, p. 511); cultural (including planting) experiments with barley, grasses, and sweetclover (E. S. R., 85, p. 615); irrigation tests with field crops, gardens, and pastures; spinning tests with cotton varieties; effects of fertilizers on yield and milling and baking quality of wheat; bin fumigation tests with wheat (E. S. R., 88, p. 190); fertilizer tests with alfalfa, sweetclover, and potatoes (E. S. R., 86, p. 620); storage experiments with sweetpotatoes; a revegetation study with pasture mixtures; pasture fertilization; and effects of rainfall on mineral composition of forage.

**Crop rotation experiments in the Ohio Valley (1925-1936)**, T. C. McILVAINE and G. G. POHLMAN (*West Virginia Sta. Bul. 306 (1943), pp. 32, figs. 4*).—Crop yields and changes in soil organic matter contents are reported for 24 cropping systems on Wheeling fine sandy loam at Lakin, differing in kind of crop, in sequence, or in cover crops used. While no one specific rotation appeared superior to all others, several features of the various rotations have given consistently good results.

Liming proved profitable on all crops except potatoes and cowpeas, and even when these crops were in the rotation beneficial effects on other crops were enough to make liming profitable in most systems. Growing of cover crops in rotations providing no winter cover helped to maintain yields. The combination of rye and vetch, the best cover crop after corn and soybeans, gave the greatest total growth. Sweetclover sown in corn made very poor growth, probably because of excessive shading. Although crimson clover was not satisfactory in these tests, it succeeds in certain sections of West Virginia. Manure gave consistently good results, and since the State is well adapted to livestock production it should be conserved and returned to cropland. Yields were satisfactory in 2-yr. rotations involving manure and cover crops, but were not so high as in longer rotations. Potato yields were higher after clover and timothy sod than after corn or soybeans, and wheat following early potatoes or soybeans cut for hay outyielded wheat after corn. Spring oats have given very poor yields and might profitably be replaced by winter wheat or winter barley in the rotation.

Maintenance and increase of organic matter appeared to be related to high yields. Return of manure, use of sod crops, and cover crops for green manure have been valuable in maintaining a good supply of organic matter.

**Regrassing for soil protection in the Southwest**, E. L. FLODY and C. G. MARSHALL (*U. S. Dept. Agr., Farmers' Bul. 1913 (1942), pp. [2]+60, figs. 45*).—Designed to aid stockmen and farmers, particularly of the Southwest, in reestablishing depleted ranges where unfavorable climatic conditions and heavy demands have made improvement of the range by natural means slow and difficult, this publication discusses latest methods of artificial revegetation proved most effective in regrassing the ranges, describes the more promising grasses and their adaptation, and explains the latest methods for harvesting seed and establishing grass on various sites under a wide range of conditions.

**Returning abandoned cultivated lands to grazing will save short-grass range**, D. F. COSTELLO. (Coop. U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.], 5 (1943), No. 1, pp. 15-17, fig. 1*).—Practices recommended to hasten range improvement and increase productivity are to defer use until the first stage with its heavy stand of Russian-thistle is replaced by a perennial weed cover; stock land conservatively in all recovery stages following Russian-thistle; defer grazing of weed stages, if possible, until late summer or early fall; base estimates of desirable stocking rates on blue grama and buffalo grass when they appear in the advanced stages; use abandoned fields in conjunction with native grasslands

where feasible; and do not plow up abandoned lands making good recovery to native grass.

**Forage improvement on sagebrush-grass range will produce more meat for victory.** C. H. WASSER (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 4, pp. 3-5, fig. 1*).—Grading with a road grader, raiiling, or burning dense sagebrush ranges with an original scattered stand of grass has resulted in substantial increases in grass density and twice as much grass forage. The greatest increase in forage yield, three times that of untreated range, was obtained by clearing off sagebrush in the fall and reseeding to crested wheatgrass the next spring. To hasten grass revegetation it is advisable to protect or restrict grazing until after seed maturity the season before and one or more seasons after treatment.

**Reseeding to increase the yield of Montana range lands.** L. R. SHORT. (Partly coop. Mont. Expt. Sta.). (*U. S. Dept. Agr., Farmers' Bul. 1924 (1943), pp. [2]+26, figs. 13*).—Essential information for ranchers wanting to increase their forage supply deals with best conditions for sowing seed in regrassing nonproductive range lands; merits of crested wheatgrass (E. S. R., 72, p. 181; 85, p. 473), smooth bromegrass, yellow sweetclover, and other promising species for different sites; times and methods of sowing; management of reseeded range; and costs of and returns from reseeding.

**Seeding permanent pastures.** E. M. BROWN. (Coop. U. S. D. A.). (*Missouri Sta. Cir. 244 (1942), pp. [4]*).—Recommendations are made on seed mixtures for different purposes and soil conditions, soil preparation and treatment, time to plant, companion crop, and the reseeding of untillable pastures.

**The effect of nitrogen fertilization of permanent pastures on seasonal distribution of yields and on nitrogen recovery in the herbage.** R. R. ROBINSON and W. H. PIERRE. (W. Va. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron., 34 (1942), No. 8, pp. 747-764, figs. 4*).—Summer applications of N to the seven permanent pastures (E. S. R., 80, p. 333) did not give satisfactory increases in yield during summer unless soil moisture was adequate, yet plats receiving part of the N in summer made about the same total yield during the period 1930-36 as plats that received all of the N in spring. This favorable response to summer N, which may have a definite place in a program of intensive dairying, was obtained at both 100 and 200 lb. of sodium nitrate per acre per year. Values for percentage N recovery ranged from +92 to -51, depending on the season, botanical composition of the pasture, soil fertility level, and amount of N fertilizer added.

**Comparison of the effect of clipping and grazing treatments on the botanical composition of permanent pasture mixtures.** M. A. HEIN and P. R. HENSON. (U. S. D. A.). (*Jour. Amer. Soc. Agron., 34 (1942), No. 6, pp. 566-573*).—The relative frequency of Kentucky bluegrass, and to a lesser extent of redtop and white clover, increased in the eight pasture mixtures (E. S. R., 80, p. 468) under grazing with sheep. Orchard grass remained unchanged, although in combination with perennial ryegrass it declined under grazing. Timothy gained under clipping, although only a small amount remained at the end of the 4-yr. period. The much greater frequency of perennial ryegrass under grazing than under clipping was attributed to failure of sheep to graze the species properly. Clipped plats in late summer contained more weeds, particularly crabgrass, than grazed plats. Clipping, in general, as evidenced by the lower total relative frequency of the grasses, was more severe than grazing, partly due to the added fertility from droppings under grazing.

**Interrelationships of legumes and grasses grown in association.** J. L. ROBERTS and F. R. OLSON. (Ind. Expt. Sta.). (*Jour. Amer. Soc. Agron., 34 (1942), No. 8, pp. 695-701*).—Redtop, Kentucky bluegrass, Kansas common al-

alfalfa, lespedeza (*Lespedeza striata*), Wisconsin Dutch white clover, white sweet-clover, mammoth red clover, and alsike clover were grown in the greenhouse in all possible pure stands and combinations of one grass with one legume. No cases were observed where both legume and grass were either benefited or injured by associated growth as compared to growth in pure stands. In general, when one component of a mixture produced more dry weight or total N in mixture than in pure stand, the other produced less when in mixture. Differences in yield of a grass in associations studied could be explained by differences in amount of associated competing legume tissue, with the possible exception of relatively high yields of grass in association with red clover. In several mixtures, greater yields of dry weight and N were obtained from mixtures on a unit area of soil than from pure stands of a grass and a legume each on one-half unit area. Gains due to association were largest when a legume with vigorous growth habits was associated with a grass with weak growth habits.

**The effect of dew on the curing of hay,** H. B. HARTWIG. (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 5, pp. 482-485).—In 35 of 47 paired comparisons made during 1940 and 1941 hay was drier at 5 p. m. when cut at 8 a. m. while wet with dew than when mowed later after the dew had dried. New York farmers producing alfalfa, timothy, and mixed grass hay under conditions described evidently would not be justified in delaying the use of labor and machinery until dew has dried from the standing crop.

**Efficiency of various phosphate fertilizers on calcareous soil for alfalfa and sweet clover,** D. A. HINKLE. (N. Mex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 913-918, fig. 1).—Experiments reported comparing effects of phosphate fertilizers on yield and P content of alfalfa grown on Gila clay have been noted from another source (E. S. R., 87, p. 368). Annual yellow sweetclover in pot tests on this soil failed to produce as much dry weight or to absorb as much P from calcium metaphosphate as from Ammo-Phos (11-48-0) or treble superphosphate. N applied as ammonium sulfate slightly increased the absorption of P from superphosphate even though the roots were inoculated.

**Boron fertilization of alfalfa and other legumes in Oregon,** H. E. DREGNE and W. L. POWERS. (Oreg. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 902-912, figs. 5).—When alfalfa in field trials in different localities received B as borax and boric acid, yellowtop was controlled with 30 lb. of borax per acre. B may be applied to alfalfa as granular borax and sown like clover seed at rates of from 30 to 60 lb. per acre. Fall application appears preferable in arid sections and spring treatments in the humid sections of Oregon. B deficiency symptoms of alfalfa are described, and B contents of yellowed and normal plants are compared to the supply of available B in the soil. Most soils of the Willamette Valley and those west of the coast range in Oregon seem to be low in B. Certain sandy leached soils respond to B applications.

**The effects of cutting systems on alfalfa,** B. A. BROWN and R. I. MUNSELL ([Connecticut] Storrs Sta. Bul. 242 (1942), pp. 23, fig. 1).—Alfalfa grown on Charlton fine sandy loam in three experiments, 1934-40, was variously subjected to as many as 19 different systems of cutting for one or two seasons, and some plats also received additional fertilizer, especially P and K. Yields, composition of roots, and stands are discussed with special reference to relative merits of cutting alfalfa two and three times per season.

The three-cutting systems usually yielded more than corresponding two-cutting systems during the current season, but less the next season when all plats were cut twice and on the same dates. Largest yields of protein and probably

of digestible nutrients were obtained from three medium-stage (41-50 days old) cuttings per season, which resulted in very poor stands, especially when practiced for 2 successive years. While high yields of dry matter and good stands resulted from either two or three late-stage (more than 50 days old) cuttings per season, the hay, especially the June crop, was of inferior quality. Early-stage (less than 40 days old) cuttings were excellent in quality but yielded much less than either the medium- or late-stage systems, and three early cuttings per season were very injurious to stands.

After mowing, the percentages of sugars plus starch in the roots decreased for about 20 days but increased consistently after 30 days. Root storage was most rapid in the 41-50-day period after cutting. The largest and most consistent reductions in carbohydrates occurred between a September 20 third cutting and October 15. Even with third cuttings as late as October 15, roots decreased in reserves between then and November 15. Carbohydrates in roots, especially in fall, were closely related to percentages of alfalfa surviving winter.

**Green and air-dry weights for determining hay yields of varieties of alfalfa,** R. M. WEIHING. (Colo. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 877-882).—The percentage of dry matter in a number of alfalfa varieties was determined in forage green and air-dried under cover. The percentage of dry matter in green alfalfa varied enough between some varieties at the time of cutting to make forage yields based on green weights inaccurate. Green weights evidently should be reduced by plats to oven dryness, to an exact percentage of dry matter, or to air dryness. Forage yields of varieties based on samples or plats air-dried under cover were nearly as accurate as those based on oven-dry weights. For comparisons between cuttings or years, air-dry forage yields should be reduced to a definite percentage of dry matter.

**Plot technic studies with navy beans,** E. E. DOWN and J. W. THAYER, JR. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 919-922).—Analysis of data from bean plats involving a condition of severe competition between contiguous plats of different row widths, 1937-39, 1941, revealed that the three-row plat, discarding border rows, was the maximum width needed for an accurate comparison. Yields of one-row plats were too subject to competition for comparisons.

**The mineral content of various clones of white clover when grown on different soils,** R. R. ROBINSON. (U. S. D. A. coop. expt. stas.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 933-939).—When eight clones of white clover, increased vegetatively, were grown in the greenhouse on five widely different soils, marked differences were obtained in both yields of dry matter and in the Ca, P, and K contents of the different clones. Clones relatively high in Ca on one soil were also relatively high in Ca on other soils. Relative differences in P and in K contents tended to be maintained on different soils, but the agreement was not as close as with Ca. No relation was found between the mineral content of clones and their ability to grow at low levels of lime and P.

**The chemical composition, growth, and certain deficiency symptoms of carpet grass, *Axonopus affinis*, as affected by lime and fertilizer mixtures,** R. E. BLASER and W. E. STOKES. (Fla. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 8, pp. 765-768, figs. 2).—The growth and Ca, P, and K contents of carpet grass on Bladen fine sand (deficient in P, N, K, and Ca) were significantly better with a top dressing of lime and complete fertilizer than without fertilizer. Omission of Ca, P, or K from the fertilizer produced carpet grass which was lower in Ca, P, or K, respectively, and also resulted in lower grass yield. When P was omitted from the mixture, the grass was dull green to purplish green in color, believed characteristic of P deficiency. P deficiency

symptoms also occurred without fertilizer but were altered by the presence of Ca, K, and N. K deficiency symptoms (burning of blade tips) were present when K fertilizer was omitted from the treatment.

**Evaluation of some morphological characters of corn in respect to their use in forecasting yield, K. R. KELLER.** (Iowa Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 940-953).—Interrelationships between certain measurable morphological plant characters and the relationship of these characters before maturity to final yield in bushels per acre were studied. Leaf height and ligule height, plant height increase and dry weight increase up to flowering, and actual and estimated leaf area were shown to be highly correlated. Plant height, ear size, and number of ears (August measurements) were used to predict yields of both double- and single-cross hybrids. "The general approach of using regression equations computed from various plant measurements appears to offer some promise as a method of forecasting yields of corn."

**The chemical composition of the cotton plant and the uptake of nutrients at different stages of growth, I. C. OLSON and R. P. BLEDSOE.** (Coop. U. S. D. A.). (*Georgia Sta. Bul.* 222 (1942), pp. 16, figs. 4).—The time and rate of absorption of plant foods by cotton were studied, 1939-40, under field conditions on fertilized Cecil and Tifton sandy loams and Clarksville gravelly loam, representative of the Piedmont, Coastal Plain, and Limestone Valleys, respectively. These soils are acid and low in base-exchange capacities, organic matter, and mineral nutrients. See also a note on similar work with the pimiento (E. S. R., 85, p. 51).

Dry weight on Cecil soil (producing 2,000 lb. of seed cotton) averaged 9,720 lb. per acre, Tifton (495 lb. of seed cotton) 6,176 lb., and Clarksville (807 lb. of seed cotton) 5,041 lb. The quantity of nutrients (N,  $P_2O_5$ ,  $K_2O$ , CaO, and MgO) absorbed from the three soils totaled 538, 393, and 311 lb., respectively. On the Cecil and Tifton soils the heaviest uptake of nutrients occurred from early-boll formation to maturity, while on Clarksville soil more was taken up during the early-square to early-boll stage. On Cecil soil absorption of nutrients was greatest 105 days after planting, when boll formation was rapid. At 120 days or longer after planting dry weight production and nutrient absorption was largely confined to the bolls. Some translocation of nutrients from plants to bolls occurred at the late growth stages. The amount of nutrients found in the cotton plant exceeded that ordinarily added in fertilizer mixtures, indicating the importance of plant residues in maintaining the fertility of cotton soils. The average amounts of nutrients found in the mature plants for all three soils approximated N 104 lb.,  $P_2O_5$  38,  $K_2O$  97, CaO 132, and MgO 43 lb.

**Row widths and cotton production, D. M. SIMPSON and E. N. DUNCAN.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 6, pp. 544-552).—Review of row width experiments with cotton at several stations indicated that narrow rows yield more per acre while wider rows yield more per row. Since planting and cultivating operations are done by the row, row footage per acre is important in determining production costs. Row widths may be varied from 2.5 to 4.5 ft. without materially changing cost of cultivation per row, and, in general, should be adjusted so as to result in the lowest cost per pound of cotton produced or the greatest production return for labor and equipment. In experiments at Knoxville, Tenn., 1938-40, yields of cotton per row increased consistently and profitably as row widths were widened from 2.5 to 4.5 ft. Optimum row widths may depend upon local conditions regarding land value, labor, and equipment costs.

**Observations of kudzu, *Pueraria thunbergiana* Benth., seedlings, P. TABOR.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 5, pp. 500-501).—Responses to different cultural and environmental factors in nurseries.

**Lespedeza in the Coastal Plain area**, J. I. STEPHENS. (Ga. Coastal Plain Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 7, p. 685).—Annual lespedezas thrived in low and moist sandy soils but made poor growth on uplands under cultivation, probably due to nematodes. "Annual lespedeza appears unable to tolerate nematodes when associated with drought."

**Studies of some factors affecting fruit setting in *Solanum tuberosum* in the field in Louisiana**, M. T. HENDERSON and E. L. LECLEER. (U. S. D. A. coop. La. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 2, pp. 67-76).—Bagging of potato flower clusters was detrimental to fruit setting in 1940 and 1941, but kraft-paper bags were more satisfactory than cheesecloth bags. Application of pollen at time of emasculation was relatively ineffective in inducing fruit set in the Katahdin variety. One pollination 24 hr. after emasculation was as good as pollination at emasculation followed by a second pollination 24 hr. later. High temperature and low moisture or low moisture proved unfavorable to fruit setting. In conducting a potato-improvement program by breeding, the breeder evidently should arrange for pollination during a period in which relatively low temperature and adequate soil moisture conditions normally prevail.

**High proportion of labor in growing sugar beets can be saved in 1943 by mechanizing**, E. M. MERVINE. (Coop. U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.]*, 5 (1943), No. 1, pp. 3-4, fig. 1).—Use of cracked seed in single seed-ball planters, mechanical thinning by cross-blocking, and mechanical harvesting are described as labor saving.

**Influence of some soil and cultural practices on the sucrose content of sugar beets**, G. C. KENT, C. M. NAGEL, and I. E. MELHUS. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 17 (1943), No. 2, pp. 163-173, fig. 1).—Average acre production of sucrose in different commercial fields of sugar beets in northern Iowa, 1937-40, varied from 2,023 to 4,417 lb., sucrose percentage from an average of 11.85 to 16.48, and beet yields from 7.57 to 13.40 tons per acre. While the highest sucrose yield resulted from the greatest tonnage and highest sucrose percentage, no relation was found between tonnage and sucrose percentage of beets. In 1937 sucrose production averaged 3,487 lb. per acre on fields planted before May 14 and after May 18, 3,023 lb.; planted on April 29, 1938, 3,630 lb. and planted on May 29 averaged 2,709 lb. Tonnage yield of beets was greater on muck than on mineral soils, yet beets grown on mineral soil contained a higher percentage of sucrose. The maximum percentage of sucrose was not found in beets harvested before October 1, 1938-40, but little appeared to be gained in sucrose percentage by leaving beets in the ground after October 7-10. When 1 in. or more of rain fell during the last half of the harvest season, or after October 15, the sucrose percentage did not decrease over 0.2 percentage points in the first 3 days after the rain, but after from 7 to 10 days the decrease amounted to from 0.5 to 4.2 points. Subsequently, the sucrose percentage rose. If beets cannot be lifted within 3 days after 1 in. of rain falling during the last half of the harvest period, they should, if possible, be left in the ground at least 10 days after the rain.

**Responses of biennial sweet clover to moisture, temperature, and length of day**, T. J. SMITH. (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 10, pp. 865-876, fig. 1).—White (*Melilotus alba*) and yellow (*M. officinalis*) biennial sweet-clovers were grown under varying conditions of temperature, moisture, and exposure to daylight (11-hr. normal and 17-hr. day) both in field and in pots in the greenhouse at Columbus, Ohio. Longer days, within limits studied, decreased the proportion of total plant weight in the roots, increased top growth, restricted crown bud formation, and reduced the percentages of N and total carbohydrates in the roots. Under the 17-hr. day biennial plants bloomed within 3 mo. after planting. Cool temperatures increased the proportion of total plant weight in

the roots. Low moisture supply increased root weights. The two species were very similar in contents of N, total sugars, starch, polysaccharides, and total carbohydrates.

**The relations to yield of certain plant characters of winter wheat as influenced by different tillage and sequence treatments, L. F. LOCKE, O. E. RAUCHSCHWALBE, and O. R. MATHEWS. (U. S. D. A.). (Jour. Amer. Soc. Agron., 34 (1942), No. 7, pp. 628-645, figs. 3).**—Plant characters of wheat causing differences in yield between certain crop sequences and tillage methods were studied in plats at Woodward, Okla., 1929-34, when seeded to Turkey wheat on the same date, usually at the same rate, and with the same type of drill. More than 95 percent of the variations in yield between treatments and between years were explained by number of kernels per unit area, which was determined more by number of heads per unit area than by kernels per head. Number of heads per unit area and plant height were also good indicators of yield. Excepting number of kernels per unit area, characters studied differed in their relative effect on yield in different years. On the average, head characters were unimportant in fixing yield. Continued adjustments made throughout the life of the plant tend to maintain it in a condition to take advantage of existing moisture and fertility conditions, and the times when adjustments occur modify the relative importance of different plant characters.

**Fairfield wheat, G. H. CUTLER (Indiana Sta. Cir. 276 (1942), pp. 8, figs. 4).**—Fairfield, developed from a cross between Purkof and Fulhio wheats, is characterized by adaptation to a wide range of soil and climatic conditions, high grain yields, superior winter hardiness, suitability for combine-harvesting, and high resistance to loose smut and mosaic. Comparative data on milling and baking qualities of Fairfield and other standard winter wheats indicate that it possesses desirable soft wheat characteristics.

**Seed inspection and testing during 1942, M. T. MUNN (Farm Res. [New York State Sta.], 9 (1943), No. 1, pp. 13, 15).**—Violations of the seed law in regard to crop variety, purity, weed seeds, noxious weeds, and germination are tabulated and discussed for numerous official samples of farm crop seeds collected in 1942.

**Legume inoculant tests for 1942, A. W. HOFER (Farm Res. [New York State Sta.], 9 (1943), No. 1, p. 7).**—Results of tests of 73 commercial cultures for inoculation of alfalfa, clover, peas, beans, lima beans, soybeans, and birdsfoot trefoil are tabulated.

**The dissemination of prickly pear seed by jack rabbits, F. L. TIMMONS. (U. S. D. A. coop. Kans. Expt. Sta.). (Jour. Amer. Soc. Agron., 34 (1942), No. 6, pp. 513-520, figs. 2).**—Droppings of jack rabbits that had fed upon ripened pricklypear (*Opuntia macrorrhiza*) fruits, collected in a cactus-infested pasture at Hays, Kans., averaged about 2.5 seeds per pellet, while those found in nearby uninfested fields only occasionally contained seeds. Such seeds germinated about 50 percent higher than seeds from dried fruits. Jack rabbits evidently are important agents in dissemination of viable pricklypear seed through western Kansas pastures.

## HORTICULTURE

**[Horticultural studies by the Arkansas Station] (Arkansas Sta. Bul. 428 (1942), pp. 13-15, 17, 49-51).**—Among studies, the progress of which is discussed, are the thinning of peach fruits and the pruning of apple and peach trees, both by J. R. Cooper; the effects of mulching on the strawberry, by J. E. Vaile; and the placement of fertilizers for vegetables, the value of lime in vegetable culture, staking and pruning tomatoes, irrigation of vegetables, nitrogen require-

ments of the strawberry, the culture of the strawberry, and the value of stable manure for vegetables and strawberries.

[Horticultural studies by the Oklahoma Station] (*Oklahoma Sta. Bien. Rpt. 1941-42, pt. 1, pp. 39-40, 42-45, 87-88, figs. 2*).—Among studies discussed are the testing of new varieties of fruits and vegetables, irrigation of vegetables, fertilizers for vegetables, use of preharvest sprays to reduce dropping of fruits, effect of high temperature on the strawberry plant, methods of handling freeze-injured grapevines, poultry manures for grapes, methods of propagating trees and shrubs, and the culture of greenhouse plants.

Victory gardens, V. R. BOSWELL (*U. S. Dept. Agr., Misc. Pub. 483, rev. (1943), pp. 16, fig. 1*).—As in the earlier edition (*E. S. R., 87, p. 58*), this presents simple, practical information to aid the home gardener.

The farm garden, J. H. and W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 1673, rev. (1942), pp. [2]+67, figs. 26*).—This revised publication (*E. S. R., 66, p. 432*) includes general information on planning, planting, fertilization, and cultural requirements of specific vegetable crops.

An experimental mechanism for the band-placing of fertilizer in irrigated beds, A. E. GRIFFITHS. (*Ariz. Expt. Sta.*) (*Amer. Soc. Hort. Sci. Proc., 40 (1942), pp. 539-544, figs. 3*).—A descriptive account is given of the structure and operation of a single-bed experimental sled which provides for the application of fertilizer and the drilling of seed in a single operation. The device was particularly effective with simple, powdered, inorganic types of fertilizer, but gave good results with such materials as blood meal or finely divided goat manure.

Nutrient solution culture of greenhouse crops, R. B. WITHROW, J. P. BIEBEL, and T. M. EASTWOOD (*Indiana Sta. Cir. 277 (1943), pp. 27, figs. 2*).—This is a revision of Circular 232 (*E. S. R., 78, p. 782*).

The influence of methods of heating and covering electric hotbeds on field production of vegetables, A. M. PORTER and M. L. ODLAND. (*Univ. Conn.*). (*Amer. Soc. Hort. Sci. Proc., 41 (1942), pp. 251-254*).—Cellulose acetate film proved better than glass as a cover for lettuce plants, and the heat of Mazda lamps was better than that from heating cables for cauliflower. From the standpoint of quality, cool-season crops grew better with the heat of Mazda bulbs and film for plant protection. With warm-season crops, such as tomatoes and peppers, the yields were larger from cable-heated beds but the increases were not sufficient to justify the higher cost over bulb heat.

Vegetable storage will help win the war, A. M. BINKLEY (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 4, pp. 12-13, fig. 1*).—Suggestions are made as to the possibilities in the storing of vegetables, with particular attention to temperature, moisture, and ventilation requirements. In addition, the relation of the condition of the crop and the variety of vegetables are considered.

A comparison of varieties of Refugee beans, W. T. TAPLEY (*Farm Res. [New York State Sta.], 9 (1943), No. 1, pp. 14, 16*).—Yield and other related information is presented for five varieties—Idaho, U. S. No. 5, Sensation 1066, Sensation 1071, and Medal.

A study of methods for planting beets, M. L. ODLAND and A. M. PORTER. (*Univ. Conn.*). (*Amer. Soc. Hort. Sci. Proc., 41 (1942), pp. 255-258, fig. 1*).—The differences in yield obtained in two methods of planting beet seed, (1) an excess of seed with subsequent thinning and (2) sufficient seed to establish a stand without later thinning, were not sufficient from the growers' standpoint to result in definite recommendations. The method of planting would depend on the cost of seed, purposes for which the crop was grown, etc. Even in testing beet varieties, either method should prove satisfactory.

**Great Lakes, a new head lettuce variety adapted to summer conditions,** K. C. BARRONS and T. W. WHITAKER. (Coop. U. S. D. A.). (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 252-254, fig. 1).—A description is presented of a new lettuce variety selected from among breeding strains developed by the U. S. Department of Agriculture in California and tested by the Michigan Station because of its ability to form solid heads under warm weather conditions and freedom from early seed stalk formation. In addition, the new variety was observed to be free from tip burn at times when Imperial 44 and Imperial 847 were badly injured.

**Nutrient absorption by a summer crop of lettuce in Salinas Valley, California,** O. A. LORENZ and P. A. MINGES. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 523-527).—The nitrate nitrogen in the midrib of the wrapper leaves of lettuce plants grown on plats not receiving nitrogen varied from approximately 240 p. p. m. 2 weeks after thinning to a low of 140 p. p. m. at the time of market maturity. Plants on soil receiving 480 lb. of ammonium sulfate per acre contained 500 p. p. m. of nitrate nitrogen at market maturity. Applications of K or P fertilizers to the soil did not increase the amounts of these elements found in the plants. Applications of nitrogen did not have any effect on the K or P contents of the plants, an indication of the natural high content of P and K in the soil used. The entire lettuce crop at market maturity had absorbed 47 lb. of nitrogen, 7 lb. of phosphorus, 117 lb. of potassium, and 30 lb. of lime.

**New pea varieties compared for yield and plant characters,** W. D. ENZIE (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 8-10, fig. 1).—Information is given on the ripening season, plant height, pod length, yield, etc., of a number of pea varieties, including recent introductions such as Greenland, Ranger, Atlas, Shasta, and Miracle.

**A comparison of the chemical composition of artificially produced parthenocarpic fruits and normal seeded fruits of peppers,** B. E. JANES. (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 432-436, figs. 3).—Analyses of the fruits of the California Wonder pepper in which parthenocarp was induced by treatment with 1 percent indolebutyric acid in lanolin, and of control fruits of the same age obtained by pollination, showed very few differences in composition. The dry weight expressed as percentage of the fresh weight was nearly equal in both types of fruit until ripening began, when the rate of dry weight formation became more rapid in the parthenocarpic fruits. When carbohydrates were calculated on a dry weight basis there were no differences between the two types of fruit, but on a fresh weight basis there was from 1 to 1.5 percent more sugar in the parthenocarpic fruits than in the seeded fruits. Total nitrogen was the only constituent other than moisture in which a consistent difference was found between the parthenocarpic and the seeded fruits.

**Plant- and fruit-pruning as a means of increasing fruit set in muskmelon breeding,** E. A. WOLF and J. D. HARTMAN. (Ind. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), pp. 415-420, fig. 1).—Of six fruit and plant pruning experiments, the one in which plants were pruned to a main and two axillary branches, from which terminal buds and all growing points (except the blossom to be pollinated) were removed, proved most effective, with 79.5 percent of the pollinations resulting in success. Fruit pruning had a noticeable effect on the number of available hermaphroditic flowers produced by the plants. On completely unpruned plants, such flowers became rare as the plant increased in size. Pruning had no material effect on the length of time required to mature a given fruit.

**An inexpensive method of growing tomato plants on the farm,** K. C. BARRONS and S. B. APPLE (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 229-235,

fig. 1).—A simple cloth-covered frame is described, with information as to its operation and costs. A comparison in 1942 of home-grown frame plants and southern-produced plants was clearly in favor of the frame tomatoes, both in percentage of living plants and returns per acre.

**The Early Chatham tomato**, P. H. BOWSER (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 245-248, figs. 2).—This new tomato, which ripened its fruits at least 1 week earlier than Earliana, was introduced by the Upper Peninsula Substation. It was found of real merit in northern gardens where the frost-free period is short. The plant is determinate in growth, and the fruits are small but desirable in shape, color, and quality.

**Plant-tissue tests as a guide to fertilizer treatment of tomatoes**, E. M. EMMERT (*Kentucky Sta. Bul.* 430 (1942), pp. 48).—Rapid tissue tests were made upon the foliage of tomatoes grown in soil and sand cultures providing a wide range of available N and P. Correlating the results of observations with growth and fruiting behavior, it was evident that different levels of N and P were needed at different stages in the development of the tomato plant. For example, in the early vegetative period before much blooming occurred the concentration of N should be well above 1,000 p. p. m. in the leaves, but as blooming increased and the fruit began to set, the N concentration should drop below 1,000 but be held well above 500 p. p. m. In the early stage P should be up to 200 p. p. m., and in the fruiting stage at least as high as 400 p. p. m. Differences in soil volume, in length of day, and in moisture influenced the results considerably. One treatment that showed particular promise in diminishing the effect of excess N and increasing fruit set was the placement of a heavy band of phosphate at a 2-in. depth as close to the plants as practical, just before fruit setting. Large applications of slowly available nitrogenous materials should be avoided with tomatoes growing on naturally fertile soils since the N from such materials might become available in excessive amounts at the time of fruit setting. The technics of plant-tissue tests are discussed.

**Natural crossing in tomatoes as related to distance and direction**, T. M. CURRENCE and J. M. JENKINS, Jr. (Minn. and S. C. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 273-276, fig. 1).—In identical arrangements, plantings of Pritchard tomatoes surrounded with a potato leaf variety were grown at St. Paul, Minn., and Charleston, S. C. At St. Paul the largest amount of crossing recorded on any one plant was 5.2 percent, with numerous plants yielding no evidence of crossing. No crossing was recorded beyond 42 ft. in the direction of the prevailing wind. At Charleston the total amount of crossing was slightly less, with a maximum of 5.0 percent recorded. The pollinating insects apparently followed the path of least resistance, as higher crossing was observed in the direction of the prevailing wind.

**Nematode resistance test of tomatoes**, F. A. ROMSHE. (Okla. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 40 (1942), p. 423).—Of 221 lots of tomatoes (including introductions from South America) planted on an area heavily infested with nematodes, 9 lots of *Lycopersicon peruvianum* were completely free of root knots and 10 plants of the husk tomato were practically free. Since adjacent plants of other types, including garden varieties, were heavily infested, it was evident that the above kinds possessed actual root knot resistance.

**Fruit industry problems of 1943**, V. R. GARDNER (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 208-210).—Suggestions are given as to pruning, soil management, spraying, and the handling of fruit under the difficult conditions of shortage of labor, materials, etc.

**Careful planning of orchard work can help alleviate effects of labor shortage later**, F. M. GREEN (*Colo. Farm Bul. [Colorado Sta.]*, 5 (1943), No. 1,

pp. 7-10, fig. 1).—Suggestions are made as to the more efficient handling of orchard operations such as pruning, cultivation, spraying, fruit thinning, and harvesting.

**Improved rootstocks and some problems they present**, H. B. TUKEY (*Farm Res.* [New York State Sta.], 9 (1943), No. 1, pp. 18-19, figs. 2).—Several of the Malling rootstocks are discussed with respect to their effect on the size of the tree, with comments on the need of careful handling in the nursery to prevent mixtures since the resulting budded trees vary greatly in size and usefulness.

**A legume program for orchards on sandy soils**, N. L. PARTRIDGE (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 249-252).—In view of the probability that certain fertilizing materials, particularly nitrogenous substances, will be limited in supply during the war, various legumes such as sweetclover, soybeans, vetch, and alsike clover, sown singly or in combination with nonlegumes, are discussed as to their value in maintaining orchard fertility.

**A study of some phases of apple production in southern New Jersey** (*New Jersey Stat. Bul.* 703 (1942), pp. 16, fig. 1).—Based on a detailed survey over a 2-yr. period on seven representative orchards in Burlington and Gloucester Counties and on general knowledge, suggestions are presented with a view to the improvement of apple culture in southern New Jersey. Among subjects discussed are the financing of orchard enterprises, the keeping of accurate records, the selection of proper soils, soil rotations and management, the use of lime to maintain effective soil reactions, varieties, fruit thinning, fertilizers, spraying, etc.

**Filler apple trees and their management**, C. E. BAKER (*Indiana Sta. Bul.* 474 (1942), pp. 14, fig. 1).—In 1934, at the beginning of the twelfth growing season, part of a Grimes Golden and Delicious orchard originally set 20 by 20 ft. was thinned so that the trees stood 28.5 ft. apart. As compared with nonthinned trees, the thinned yielded less gross income per acre during the period 1935-39. However, the thinned trees were individually more productive, showing that the crowding was exerting a depressing effect on yield per tree. As measured by trunk girth increase and general vigor, the spaced trees had benefited by the release. It was difficult to obtain good fruit color on the crowded Delicious trees, and even with Grimes Golden the finish on the fruits was not satisfactory in the crowded area. It was more difficult to control insect and fungus pests in the unthinned section, and during a prolonged drought the unthinned trees suffered considerable loss of leaves and fruits while the thinned came through without damage. At the end of the seventeenth season, the unthinned plots were also thinned. The accumulated damage from crowding was such as to cause continued lower production following this release.

**Effect of spray materials on finish and keeping quality of apples**, E. J. RASMUSSEN (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 263-271, figs. 3).—Bordeaux mixture and certain proprietary copper materials when applied to apple trees in Michigan in an all-season schedule resulted in fruit of poor finish as compared with that of trees sprayed with lime-sulfur or wettable sulfur. Of varieties studied, McIntosh and Jonathan were the most susceptible, and Delicious and Northern Spy the most resistant to copper injury. Rhode Island Greening, Grimes Golden, Wagener, and Wealthy were intermediate. None of the copper fungicides used proved safe on McIntosh at any stage. With Jonathan they were used safely in the later cover sprays in some years. The use of copper materials in all-season schedules is not recommended for Northern Spy or Delicious, but they may be possibly substituted for sulfur in some of the late applications. Russeted fruits are not only inferior in appearance but they lose weight and shrivel rapidly in storage.

**Peach culture in Missouri**, T. J. TALBERT (*Missouri Sta. Bul.* 455 (1942), pp. 36, figs. 19).—Information is presented with respect to climatic factors involved in the success of peach growing, the selection of sites and soils, varieties, pollination, contour planting, soil management, fertilization, pruning, fruit thinning, insect and fungus enemies, spraying, harvesting and marketing, etc.

**Recommended peach varieties for New York State**, L. M. VAN ALSTYNE and H. O. BENNETT (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 16, 17).—A number of varieties covering the fruiting season are briefly discussed.

**Soil management for roses in the greenhouse**, L. C. WHEETING (*Washington Sta. Bul.* 421 (1942), pp. 20, figs. 4).—The development of yellow or mottled foliage on Tallsman roses has caused severe losses to Washington greenhouse growers. The continued use of hard water resulted in soil pH values of 8.5 and above and promoted a condition in which plants could not obtain sufficient iron. The use of fertilizer materials which leave acid residues in the soil counteracted the harmful effects of the hard water. Sulfur applications were also beneficial. The best yield of roses was obtained at pH values between 6.0 and 7.0. The best production was obtained by maintaining a relatively high concentration of K, a medium to low concentration of P, and a medium supply of available N. An NPK ratio of 2:2:4 is suggested.

**The cause and control of defoliation in cut holly**, J. A. MILBRATH and H. HAFTMAN (*Oregon Sta. Bul.* 413 (1942) pp. 11, figs. 2).—Holly packed wet and stored where ethylene was present did not lose its leaves in 30 days when the temperature was held at 31° F. At 36°, 25 percent of the leaves were lost, and holly was completely defoliated after 2 weeks in a room at 42°. Packed wet and stored where there was no ethylene present holly did not lose its leaves in 30 days at either 31° or 36°, but started to lose leaves in 2 weeks at 46°. When stored wet in an open building, where the temperature ranged from 20° to 60° but remained in the lower half most of the time, holly was bright and fresh after 40 days. Partial dehydration after cutting prevented loss of leaves, apparently by limiting the development of the abscission layers. The dipping of holly branches in solutions of  $\alpha$ -naphthaleneacetic acid was helpful in preventing abscission. A 0.01-percent solution prevented abscission entirely for a 14-day period at 70° to 80°. Comparable check lots dipped in water lost all their leaves in 3 days. Even a 0.001-percent solution had a marked retarding effect on defoliation. No injury was observed from the hormone treatments except at excessive concentrations. No objectionable residues or deposits were left on the leaves. When treated holly was packed with apples, which give off ethylene in their ripening process, there was some defoliation, leading to the suggestion that holly should not be shipped or stored with fruit or exposed to other sources of ethylene.

**The importance of tung seed selection**, R. D. DICKEY. (Fla. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 127-130).—A comparison of the yield of seedling trees grown from parents of high-yielding capacity with that of seedlings from unselected parental sources showed the importance of selection. A study of individuals in two selected progenies showed that fairly high percentages came relatively true to type, thus confirming further the desirability of using seed of known parentage.

**Native plants as possible sources of rubber**, L. KNUDSON (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 2, 5, fig. 1).—A new method was devised for the rapid determination of rubber in plant tissues, and nearly 3,000 tests were made on leaves, roots, stems, and flowers of various species, including goldenrod, milkweed, Indian hemp (*Apocynum cannabinum*), and Russian dandelion.

**Can rubber be produced in Colorado?** (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 4, pp. 2, 15, fig. 1*).—Information is presented on progress in growing such rubber-producing plants as guayule and Russian dandelion.

**Agriculture in the Americas** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Agr. in Amer. 3 (1943), No. 1, pp. 18+[2], figs. 19*).—Among articles included are *The Technique of Plant Exchange*, by B. Y. Morrison (pp. 3-6); *More Rubber From Castilla?* by O. F. Cook (pp. 7-9); and *The Future of the Forests*, by C. L. Forsling (pp. 13-16).

## FORESTRY

**Forestry in wartime: Report of the Chief of the Forest Service, 1942** (*U. S. Dept. Agr., Forest Serv. Rpt., 1942, pp. 23*).—This administrative report contains information relating to forest resources and the war; the need of regulating cutting practices; the work of the Forest Service in the development of new and improved uses for wood, particularly in relation to the war; new sources of rubber; fire control and general management of the national forests, etc.

[**Forestry investigations by the Arkansas Station**] (*Arkansas Sta. Bul. 428 (1942), pp. 51-52*).—Information is presented on timber marketing studies and on the need of sustained yield practices for maintaining hardwood forests and hardwood lumber supplies.

**The Rainbow Forest plantations; Report of progress, 1942**, H. W. Ilcock (*Connecticut [New Haven] Sta. Bul. 464 (1942), pp. 615-702, pls. 5*).—A history and description of the forest area are presented, with an account of various destructive influences, such as insects, plant diseases, and hurricane damage in 1938, and descriptive accounts of the various experimental plats from the time of their establishment to date. Suggestions are given for the planting and management of white pine stands and on the handling of other species.

**Natural reproduction of pines in east-central Alabama**, K. A. BRINKMAN and P. A. SWARTHOUT. (Coop. U. S. D. A.). (*Alabama Sta. Cir. 86 (1942), pp. 12, figs. 3*).—A survey of woodlands in four Alabama counties revealed a lack of satisfactory young pine stands on 80 percent of the 445 plats examined, largely because of unsatisfactory older stands. An inadequate seed supply was apparently responsible for the partial or complete failure of pine reproduction on about one-half of the areas. Fires prevented the establishment of adequate stands of young pine on about 40 percent of the areas. Competition from shrubs and young hardwood trees and from the crowns of large trees had an adverse effect on about one-fourth of the areas. Grazing by cattle was harmful to survival and growth of pine seedlings, and hogs were especially destructive to young longleaf pines. Severe erosion resulted in poor reproduction, while light to moderate erosion apparently favored pine reproduction by exposing the underlying mineral soil.

**Preventing destructive fires in southern woodlands** (*U. S. Dept. Agr., Farmers' Bul. 1926 (1943), pp. [2]+15, figs. 14*).—General information is presented on the significance of woodland protection during wartime, causes of fires in woodlands including accidental and intentional burning, relation of burning to grazing values and pest control, and suggestions for the prevention and control of fires.

## DISEASES OF PLANTS

[**Plant disease work by the Arkansas Station**]. Partly coop. U. S. D. A.). (*Arkansas Sta. Bul. 428 (1942), pp. 30-35*).—Brief summaries of results are given by H. R. Rosen and C. K. McClelland on breeding of oats resistant to crown rust in relation to winter pasture usage, by V. H. Young on increasing

cotton yields by disease control, by E. M. Cralley on resistance of rice varieties to blast (*Pyricularia oryzae*), and by S. B. Locke on fungicidal control of defoliation diseases of tomato.

**Plant pathology** (*Oklahoma Sta. Bien. Rpt. 1941-42, pt. 1, p. 62-65, figs. 2*).—Brief summaries are presented of results with wheat and barley loose smut control, forecasting wheat leaf rust damage, cotton seed treatment, nematode control in sweetpotato bedding roots, and prevention of losses by plant disease surveys.

**Names for the bacterial plant pathogens**, A. J. RIKER and I. L. BALDWIN. (Univ. Wis.). (*Chron. Bot., 7 (1942), No. 6, pp. 250-252*).—A critical review of the present chaotic situation in bacterial taxonomy, with recommendations.

**Interference between bacterial viruses**.—I, **Interference between two bacterial viruses acting upon the same host, and the mechanism of virus growth**, M. DELBRÜCK and S. E. LURIA (*Arch. Biochem., 1 (1942), No. 1, pp. 111-141, figs. 6*).—Multiple infection of *Escherichia coli* with particles of two different bacteriophages resulted in complete suppression of one and normal growth of the other. This interference was studied in detail under various experimental conditions, and the bearing of the results on other cases of interference between viruses (both plant and animal) is discussed. There are 19 references.

**Interference between inactivated bacterial virus and active virus of the same strain and of a different strain**, S. E. LURIA and M. DELBRÜCK (*Arch. Biochem., 1 (1942), No. 2, pp. 207-218*).—Carrying studies of the two *Escherichia coli* bacteriophages further (see preceding abstract), it is shown that one phage, after ultraviolet inactivation, retained its ability to interfere with the growth of another phage, and a single partially inactivated particle proved sufficient to suppress growth of the second phage in one bacterium. This partially inactivated phage was adsorbed by the sensitive bacteria and inhibited their growth without lysis. It was able to interfere with growth of active virus of the same kind. This interfering activity, though more resistant to irradiation than the reproducing activity, was progressively destroyed by larger doses of ultraviolet rays. The results are believed to support the hypothesis that interference between bacteriophages is due to competition for a "key-enzyme" present in limited amount in each bacterial cell. The bearing of these findings on the problem of antiviral vaccines produced by irradiation is discussed.

**Respiration and virus diseases**, M. W. WOODS. (Md. Expt. Sta.). (*Chron. Bot., 7 (1942), No. 6, pp. 243-244*).—A review of papers on respiration in virus-infected plants.

**Optimal conditions for the hydrolysis of arabogalactan by *Aspergillus niger***, E. J. RATAJAK and H. S. OWENS (*Bot. Gaz., 104 (1942), No. 2, pp. 329-337*).

**Variations in sporulation of different isolates of *Colletotrichum destructivum***, S. J. P. CHILTON. (U. S. D. A. et al.). (*Mycologia, 35 (1943), No. 1, pp. 13-20, figs. 2*).—Among the 14 single spore isolates of the fungus studied, variant types were obtained from sectors and patches in old cultures which differed from the originals in various culture characters. Some produced very few spores, others more than the parent cultures, though the latter retained their ability to sporulate through 10 successive single spore generations. Transfers to sterile or living host tissues failed to enable poorly sporulating cultures to regain their ability to sporulate heavily. Two variants were obtained from lesions on red clover seedlings produced under sterile conditions. Conidia were predominantly uninucleate. It is concluded that the loss of sporulation in cultures was due to the occurrence of poorly sporulating types differing genetically from the original type which they replaced.

**Biochemistry of *Fusaria*:** The influence of diphosphopyridine nucleotide on alcoholic fermentation (in vivo), B. S. GOULD, A. A. TYTELL, and H. JAFFE (*Jour. Biol. Chem.*, 146 (1942), No. 1, pp. 219-224, figs. 2).—The in vivo role of diphosphopyridine nucleotide (coenzyme I) was studied and shown to be a limiting factor in alcohol production by *Fusarium trichothecoides*, suggesting that fermentation by living cells is similar to that in cell-free preparations involving oxidation-reduction reactions and phosphorus transfer.

**Growth substances and dormancy of spores of *Phycomyces*,** W. J. ROBINS and V. W. and F. KAVANAGH (*Bot. Gaz.*, 104 (1942), No. 2, pp. 224-242, figs. 4).—Dormant spores of *P. blakesleeianus* are considered to lack sufficient available Z factors for germination. Extracts of certain natural products or the Z factors furnished in the basal medium supplied the deficiency, which may also be met by treatment with heat, cold, acetate, or pyridine—thought to change the Z factors in the spores from an unavailable to an available form.

**Moisture-relation as a determinant factor in the transformation of the basidia of certain Polyporaceae,** S. R. BOSE (*Mycologia*, 35 (1943), No. 1, pp. 33-46, figs. 8).—Experimental evidence is given that it is mainly the water relations which control transformation of basidia into hyphal elongations with clamp connections and terminal spores and vice versa, species of *Polyporus*, *Polystictus*, *Trametes*, *Fomes*, and *Favolus* having been used. There are 19 references.

**Cultural differences among single basidiospore isolates of *Rhizoctonia solani*,** B. EXNER and S. J. P. CHILTON. (La. Expt. Sta.) (*Phytopathology*, 33 (1943), No. 2, pp. 171-174, fig. 1).—A total of 395 single-basidiospore isolates were obtained from 10 basidial mats occurring spontaneously on lima bean, potato, and alligator weed (*Alternanthera phylloxeroides*). Since isolates from the same mat differed in growth rate and other culture characters, it is concluded that some type of segregation occurs in basidiospore formation.

**The use of fungicides during wartime, I-III.** (N. Y. State Expt. Sta.) (*Canner*, 96 (1943), Nos. 6, pp. 16-17, 58, figs. 3; 7, pp. 14-15, 42, 44, figs. 4; 8, pp. 14-17, figs. 3).—Three papers in this series are presented.

I. *The nature of diseases on vegetable crops*, G. L. McNew.—A general introductory account.

II. *Effect of soil fertility on returns from use of fungicides*, G. L. McNew and C. B. Sayre.—The results of seed treatments of peas with Spergon and of spraying tomatoes against defoliation diseases with an insoluble copper compound (1941-42) are summarized as showing the greater effectiveness of fungicidal control on properly fertilized plats and the great loss in the value of the fertilizer from omission of the disease control treatments.

III. *Value of different seed treatments for lima beans*, G. L. McNew.—This is a progress report on tests of promising fungicides on the varieties Henderson Bush, Clark Green, and Fordhook, with the suggestion that "general treatment of lima bean seed with Spergon at about 2 oz. per bushel will be profitable." Thiosan, applied at 1 or 1.5 oz., and Fermate at 2.5 oz. should be given limited tests, with an ounce of graphite added, particularly with Fermate if the seed is to be drilled.

**Fungicidal versus fungistatic,** S. E. A. MCCALLAN and R. H. WELLMAN (*Contrib. Boyce Thompson Inst*, 12 (1942), No. 6, pp. 451-463, figs. 4).—Fifteen water-soluble chemicals were compared by methods described as to their fungicidal (lethal) and fungistatic (inhibitory) effects on spores of *Sclerotinia fructicola*, *Alternaria solani*, *Penicillium expansum*, and *Rhizopus nigricans*. Fungicidal activity cannot exceed fungistatic activity, hence the correlation between the two is high when both values are either high or low, but when fungistatic activity is high and fungicidal activity low the correlation is poor. For all four fungi the

detailed results are presented. In a few cases, addition of a small amount of unfiltered orange juice markedly lowered the fungicidal action. The fungicidal dosage response curves gave straight lines when plotted on logarithmic-probability paper. In many cases the fungicidal curves were decidedly flatter than the corresponding fungistatic curves, outstanding examples being copper sulfate, potassium dichromate, uranyl acetate, sodium arsenate, malachite green, berberine sulfate, and 8-hydroxyquinoline sulfate. Limited data indicate that the fungicidal time-response curves give straight lines when plotted on logarithmic-probability paper.

**Non-sterile soil as a medium for tests of seed germination and seed-borne disease in cereals,** J. E. MACHACEK and H. A. H. WALLACE (*Canad. Jour. Res.*, 20 (1942), No. 11, Sect. C, pp. 539-557).—Large seedbed trials indicated that if maintained in proper condition nonsterile soil could be used successfully for tests of seed germinability and of certain kinds of seed-borne cereal diseases. It was more easily handled than autoclaved soil, did not require fresh preparation for each planting, and the amount of soil-borne seedling infection was negligible when the soil was kept friable, moist, and at 20° C. Results from 120 seed lots indicated nonsterile soil to be equal in some respects and superior in others to seed tests on moist filter paper or on nutrient agar in petri dishes for testing seed germinability, seed-borne disease, and physical injury to the seed. With barley, a plating test in addition to the soil test proved necessary to indicate the amount of seed-borne *Helminthosporium teres*. A table of tentative recommendations based on tests of several thousand seed lots is given. Seed disinfection is recommended where the smut spore load exceeds 1:128,000, or where seed decay or seedling blight reduces the healthy seedlings from nondisinfected seed below 91 percent. Increases in seedling rates are recommended when the healthy seedlings, even after disinfection, are less than 91 percent but more than 50 percent. Seed germinating 50 percent or less after disinfection should be discarded.

**Chemical seed treatments for cereals and war needs,** W. CROSTER (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 12-13).—Replacing critical war materials, Spergon and Thiosan are reported effective against stinking smut of wheat but not against oats or barley smuts. Oats smut control still requires New Improved Ceresan and to a greater extent than previously.

**Environmental relationships in a seed-borne disease of barley caused by *Helminthosporium sativum*** Pammel, King, and Bakke, H. W. MEAD (*Canad. Jour. Res.*, 20 (1942), No. 11, Sect. C, pp. 525-538).—The experiments reported indicate that greatest seedling injury occurs under conditions unfavorable to the host, viz, high temperature and excessive moisture or low temperature and scant moisture, and that greatest recovery occurs at 15°-18° C. in moist soil. It was further shown that packing and fertilization of the soil increases the amount of infection though fertilization may increase the dry weight of the seedlings, that the soil microflora has little influence on the seed-borne parasite, that reduction of the O<sub>2</sub> content of a nutrient solution or of the soil from 21 to 10 percent depresses seedling growth and amount of infection, and that adding 1 percent CO<sub>2</sub> to the soil atmosphere increases the amount of seedling infection. Barley infected with *H. sativum* should thus be sown in cool, moist, well-aerated soil. There are 23 references.

**An American oat disease found in western Anatolia,** H. BREMER (*Phytopathology*, 33 (1943), No. 2, pp. 165-167, figs. 2).—A leaf spot discovered in plots of fall-sown oats in an experimental field of the Plant Protection Station at Bornova (near İzmir), western Anatolia, is shown to be identical in symptoms

and cause (*Pseudodiscosia avenae*) with a disease observed in the United States. It was at first assumed that the fungus might have been introduced from the United States, but subsequent research admits the possibility that it may be indigenous to Turkey.

**Das Vorkommen und die Verbreitung der in Rumänien den Weizenstinkbrand hervorbringenden Tilletia-Arten** [The occurrence and distribution in Rumania of the wheat bunt fungi], T. SĂVULESCU, A. HULEA, and A. STĂNESCU (*Phytopathol. Ztschr.*, 14 (1942), No. 2, pp. 148-187, figs. 7).—Four species are said to be represented, viz, *T. tritici*, *T. levis*, *T. triticoides* and *T. intermedia*.

**Cercospora herpotrichoides** Fron., causing eyespot of wheat in Great Britain, M. D. GLYNNE (*Ann. Appl. Biol.*, 29 (1942), No. 3, pp. 254-264, pl. 1).—A general account, including its history in England, its relation to lodging and to previous crops, and the losses involved.

**Physiologic races in Urocystis tritici**, C. S. HOLTON and A. G. JOHNSON. (U. S. D. A.). (*Phytopathology*, 33 (1943), No. 2, pp. 169-171).—Of the two races segregated, No. 1 (from Kansas) attacked Baart Federation, Oro × Federation-1 and Oro × Federation-26, but not Oro × Federation-38 or Oro × Federation-40, whereas No. 2 (from Washington State) attacked all of these wheat varieties and strains.

**Influence of borax and potash on alfalfa yellows**, J. B. WASHKO (*Tennessee Sta. Cir.* 83 (1943), pp. [4]).—Demonstrations in various parts of Tennessee indicated that alfalfa yellows (due to B or K deficiencies, leaf spot fungi, powdery mildew, leafhoppers, or aphids) is of common occurrence there, B deficiency apparently being the most important cause. Application of borax at 20 lb. per acre alone, or in combination with potash (more beneficial), prevented the deficiency forms and increased hay yield, plant height, and longevity of stand.

**The occurrence of amphispores in the leaf rust of bluegrasses**, J. R. HARDISON. (Wash. State Col.). (*Mycologia*, 35 (1943), No. 1, pp. 79-82, figs. 2).—Amphispores, hitherto not reported for *Puccinia poae-sudeticæ*, are described.

**The reaction of varieties of Trifolium subterraneum to leaf rust (Uromyces trifolii (Hedw.) Lev.)**, K. L. HILLS (*Jour. Council Sci. and Indus. Res. [Austral.]*, 15 (1942), No. 4, pp. 272-274).—Experimental data indicated the reactions of the varieties tested to vary from highly resistant to very susceptible. Possible explanations of the incomplete agreement with results elsewhere are offered.

**A Pythium stalk rot of corn**, C. ELLIOTT. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 1, pp. 21-39, figs. 13).—Following periods of hot humid weather at Arlington, Va., stalk rot of the lower internodes developed spontaneously in plants of two inbred lines of yellow dent corn. *P. butleri* was isolated from the rotted tissue and caused typical symptoms on inbred lines when inoculations were made under conditions of high temperature and humidity. The fungus produced infection on both wounded and unwounded inoculated corn plants but did not attack the roots. Of the 13 inbred lines of dent corn tested, 4 proved susceptible and only Ill. Hy. and Ky. 13 were resistant. Cultures of *P. butleri* from rotted cornstalks rapidly rotted squashes and cucumbers. What appeared to be the same disease was observed in a commercial field of hybrid corn near Petersburg, Va.

**Lightning injury to cotton**, A. L. SMITH. (Ga. Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 33 (1943), No. 2, pp. 150-155, figs. 2).—Considerable variation in the general appearance of lightning-struck spots in cotton fields was observed, sudden killing in circular areas resulting in those more frequently encountered.

More difficult to diagnose were the somewhat indefinite and variable spots with delayed and dispersed appearance of symptoms, without noticeable centralized killing, and extending over areas as much as 300 ft. in diameter. Immediate killing results from collapse of tissues exterior to the xylem in stems and larger roots. Surviving plants almost invariably exhibit a collarlike enlargement at or just below the soil line where the plants are completely or occasionally partially girdled. This girdling is due to the killing of cortical and cambial tissues in a band usually about 0.5 in. wide. Other symptoms on survivors include irregular longitudinally elongated necrotic areas on the stems. *Rhizoctonia bataticola*, reported as parasitic on certain Asiatic cottons, frequently invades the lower stem and roots of lightning-injured upland cotton (*Gossypium hirsutum*) in Georgia. American upland varieties are compared with varieties of *G. herbaceum* proved relatively resistant to this fungus.

**Influence of sulphur deficiency on metabolism of black mustard, S. V. EATON** (*Bot. Gaz.*, 104 (1942), No. 2, pp. 306-315, fig. 1).—The main symptoms (among others) on *Brassica nigra* were the short plants, yellow-green color of the upper leaves, and the thin leaves and stems. The chemical composition of the S-deficient stems (detailed) seemed to be due mainly to the combined influences of proteolysis and poor reductase activity. The effects of S deficiency on plants in general are summarized and compared (17 references).

**Sanidade dos batatais e trabalhos aplicados ao seu melhoramento [Potato diseases and their control]**, J. A. DESLANDES (*Bol. Min. Agr. [Brazil]*, 30 (1941), No. 9, pp. 1-39, figs. 25).—A general account with reference to Brazil, including the results of experimental work.

**Inoculation tests of potato for resistance to Phytophthora, N. J. FEDOROVA** (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 33 (1941), No. 1, pp. 73-75).—In seeking material as a basis for breeding potatoes resistant to late blight (*P. infestans*), two seasons' inoculations of a large number of varieties and seedlings of *Solanum demissum* indicated it to be a very polymorphous species, with wide ranges in susceptibility even among lines. Along with these inoculations, 22 varieties of *S. antipovichi* were also tested; a few forms were resistant, but most of them no more so than varieties of the cultivated potato. It is thus obvious that the choice of breeding material is not only important, but that every clone to be used must be thoroughly investigated.

**Potato virus X: The average severity of strain mixtures in three varieties of potato, J. G. BALD and N. H. WHITE** (*Jour. Council Sci. and Indus. Res. [Austral.]*, 15 (1942), No. 4, pp. 300-306, fig. 1).—A rapid method was evolved for inoculating this virus, the tuber itself being used both as inoculum source and instrument for inoculation. Populations of virus X strain mixtures carried in different lots of the same variety proved similar, but there were wide differences in strain mixtures carried by the three varieties used. A natural equilibrium among strains of each variety is suggested to explain these findings, and its relation to seed tuber selection is discussed.

**Influencia de la infección de la soja con *Rhizobium japonicum*, sobre el rendimiento y calidad del forraje [Influence of soybean infection with *R. japonicum* on the yield and quality of the fodder]**, E. SCHIEL and P. R. MARCO (*Rev. Argentina Agron.*, 9 (1942), No. 4, pp. 284-291, fig. 1; *Eng. abs.*, p. 291).—Two field trials were conducted with soybeans on common and on rich soils, a part of the seed in each case having been previously inoculated. On the common soil the greatly increased yield from inoculation was highly significant; on the rich soil *R. japonicum* increased only the percentage of nitrogen.

**Observaciones y ensayos culturales relacionados con el "carbon" de la caña de azúcar [Observations and culture trials with sugarcane smut]**,

W. E. CROSS (*Bol. Estac. Expt. Agr. Tucumán, No. 37 (1942), pp. 12*).—The present study of this fungus disease, first observed in Tucumán during the crop season of 1940–41, was continued at the experiment station through November 1942. Lists of varieties severely, moderately, and only slightly infected are given. Intensity of attack proved to have no relation to age of cane, date of harvesting of the preceding crop, fertility of the soil, presence of other cane diseases, degree of infestation with the cane borer, or chemical composition of the cane. Frequent irrigation in spring increased the number of shoots attacked. Climatic conditions exercised an important influence on the incidence of smut. Severe frosts at the end of winter and prolonged droughts in spring weaken the cane and occasion much delay in its development; these factors are believed to contribute to the progress of the disease. Possible control methods tried, including heavy manuring and liming and adding various chemicals to the soil, all gave negative results.

**Nutritional effects of boron on growth and development of the sunflower, B. LOWENHAUPT** (*Bot. Gaz., 104 (1942), No. 2, pp. 316–322*).—The plants showed typical B-deficiency symptoms on transfer from a complete nutrient solution to one deficient in boron or to distilled water. Boron proved necessary to stem-tip or root growth. Leaves were heavier if plants were deprived of B during the later part of their growth period. In the minus-B plants the stem tips were lower in ash, and the ash of the leaves contained more Ca though the stem, roots, and the entire plant contained less. Boron is believed instrumental in regulating the distribution of materials throughout the plant, and the Ca determinations confirm the view that there is a relationship between B availability to the plant and the utilization of Ca. There are 20 references.

**Bacteriological sterility of tissues derived from secondary crown-gall tumors, A. C. BRAUN and P. R. WHITE** (*Phytopathology, 33 (1943), No. 2, pp. 85–100, figs. 2*).—The results from over 2,000 tests are presented. No cultures from viable secondary tumor tissues from sunflower yielded cultures of *Phytomonas tumefaciens* when growth on nutrients suitable for its isolation, when thoroughly crushed and incubated in suitable nutrients, or when cut in thin slices and incubated on media known to favor growth of this pathogen. Special tests suitable for isolating small numbers of bacteria or of dormant phases, filtrable forms, viruses, or noncultivable forms were also negative. Implantation of such tumor-tissue cultures in sunflower and artichoke plants gave rise to typical crown-gall tumors that again failed to yield *P. tumefaciens* on the usual tests. Used as antigens, tumor-tissue cultures failed to reveal the organism either by agglutination or complement-fixation tests. These data are believed to provide unequivocal demonstration that tumor-tissue cultures isolated from secondary tumors are entirely free of *P. tumefaciens* or of other recognizable tumor-inciting agents. It is therefore assumed that the causal agent of crown-gall in the sunflower produces a profound change in the characteristics of certain host cells resulting in a subsequent independent, unrestrained, unphysiologic, and potentially malignant type of development. These bacteria-free crown-gall tumor cells possess many of the essential characteristics of true malignant animal cells and thus represent a potentially useful material with which to study certain basic principles involved in the etiology of malignancy.

**Peronospora tabacina Adam, the organism causing blue mold (downy mildew) disease of tobacco, E. E. CLAYTON and J. A. STEVENSON.** (*U. S. D. A.*). (*Phytopathology, 33 (1943), No. 2, pp. 101–113, fig. 1*).—In studying identification methods for *Peronospora* spp., it was found that different collections of *P. tabacina* spores vary significantly in size and that this variability is increased by collecting from different hosts. The authors' measurements were

made under very uniform conditions, but when reports by others were considered the variability was still more pronounced. Mean values for conidial size were at least  $17\mu$ – $28\mu$  by  $13\mu$ – $17\mu$ , a range too great to permit definite identification by measurements alone. The oospores were still more variable, and the only possible value in measuring them would be to determine whether they lie within the size range for the genus (about  $20\mu$ – $60\mu$ ). Neither conidiophores, conidia, nor oospores possess morphological characters distinctive for species determination. Evidence is offered that the situation in *P. tabacina* is representative of that for the genus, in that spore measurements have not provided a sound basis for species identification. The Peronosporaceae are apparently highly specialized with respect to parasitism, and *P. tabacina* is practically limited to *Nicotiana*. Pathogenicity thus appears to be the only definite basis for identifying *P. tabacina*, and it is believed to be the only species occurring on *Nicotiana*. It is thought to be native to all temperate zone regions with native *Nicotiana* floras, i. e., portions of North and South America and Australia. There are 22 references.

**Some effects of sand and nutrient supply on a physiological leaf spot of cantaloupe**, E. C. PIERCE and D. L. STODDARD. (Md. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 2, pp. 162–164).—A physiological leaf spot inducing progressive defoliation of cantaloups grown in quartz sand was inhibited by use of coarser sand and slop application of nutrients. Root aeration appeared to be the factor involved.

**Cercospora blight of carrot**, H. R. THOMAS. (Ind. Expt. Sta. coop. Univ. Calif.) (*Phytopathology*, 33 (1943), No. 2, pp. 114–125, figs. 2).—*C. carotae* attacks leaf blades and petioles of *Daucus maritimus*, *D. pulcherrimus*, *D. pusillus*, *D. hispanicus*, and *D. gingiditum*, as well as of carrot, and no marked resistance was found among *Daucus* spp. or 112 carrot varieties and selections tested in the field. The fungus germ tubes enter through stomata and advancing hyphae are intercellular at first, but intracellular invasion soon follows. The pathogen grew equally well in culture at 19°–28° C. It may persist in the soil from one crop to another and may be spread by the wind. Infected inflorescences have been observed and viable conidia found on seed from such plants, but seed transmission is deemed unimportant. Carrot seed artificially contaminated with conidia and treated with ethyl mercury phosphate or ethyl mercury tartrate as liquids (1–24,000) or dusts, mercuric chloride (1–1,000), or Spergon remained free of fungus growth when placed on sterile potato-dextrose agar. The number of leaf spots per square centimeter of leaf surface did not differ significantly among carrots sufficient in N, P, and K or deficient in K or P. Ca- and N-deficient plants developed significantly fewer leaf spots per square centimeter than complete nutrient plants. Leaf spots attained their greatest length on complete-nutrient plants, were intermediate on K- and P-deficient plants, and shortest on Ca- and N-deficient plants. More fungus growth was obtained on leaf extracts from complete and K- and N-deficient plants than on extracts from Ca- and P-deficient plants.

**Notes on hop diseases in 1941**, W. G. KEYWORTH (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 29 (1941), pp. 42–43).—Notes are presented on outstanding features of attacks by *Verticillium* wilt, nettlehead (probably virus induced), fluffy tip (cause unknown), and virus chlorosis and mosaic diseases.

**The grey mould of fruit and hops: Weeds as possible source of infection**, H. WORMALD (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 29 (1941), pp. 44–47).—In 1941 *Botrytis cinerea* was found prevalent during the first half of June and in the fall on many cultivated plants as well as on a number of weeds. It was particularly abundant on the flower heads of members of the composite family.

**Varietal resistance and mulching show promise in control of tomato fruit rot**, W. A. KREUTZER and L. R. BRYANT (*Colo. Farm Bul. [Colorado Sta.]*, 5 (1943), No. 1, pp. 12-15, fig. 1).—In tests of 119 types and varieties against the *Phytophthora capsici* rot, a disease threatening serious curtailment of the war-important canning crop in at least two of the largest Colorado tomato areas, none of the commercial sorts showed complete but some a certain degree of resistance. Fruits of all varieties and types not in contact with the ground were seldom infected under test conditions. In field tests with a heavy straw mulch there was a marked reduction in infection of fruits on the straw as compared with those in contact with the soil. Field tests with copper fungicides failed to yield the promise shown by laboratory tests, but under conditions enabling spread to fruit above the ground they may still offer possibilities.

**New spray controls anthracnose of tomato fruit**, G. L. McNEW (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 6, 7, figs. 2).—In the two preliminary tests reported Ferimate (ferric dimethyl-dithio-carbamate), with nearly 99 percent perfect control, was far and away the most effective of several fungicides tried.

**The presence of a toxin in tomato wilt**, D. GOTTLIEB. (*Minn. Expt. Sta.*). (*Phytopathology*, 33 (1943), No. 2, pp. 126-135, figs. 5).—Using a method devised for anaerobic collection of vascular fluids, tomato plants wilted by *Fusarium bulbigenum lycopersici* were found to contain a toxin in their tracheal fluids, whereas no toxins were noted in those wilted by insufficient soil water. When the cell sap of either healthy plants or those with *Fusarium* wilt was expressed from the stems under aerobic conditions, a poisonous substance was present that caused tomato seedlings to wilt when placed in the sap. There are 20 references.

**Spray trial to control spotted wilt of tomatoes**, T. T. COLQUHOUN (*Jour. Austral. Inst. Agr. Sci.*, 8 (1942), No. 4, pp. 171-172).—Spraying with tartar emetic reduced the incidence of this virus disease in the treated plats, but it is questioned whether in view of the 30 percent of infection developing therein, this could be considered control. See also a previous note by Magee et al. (*E. S. R.*, 88, p. 491).

**Heat resistant microorganisms causing spoilage in the 1942 tomato pack**, J. A. WOERZ and D. J. LENANE (*Canner*, 96 (1943), No. 10, pp. 11-12, 24).—Anaerobic rod-shaped spore-forming bacteria from the soil were found to be involved.

**Extent of injury to fruit trees during the winter of 1941-42 and what can be done about it**, N. L. PARTRIDGE (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 255-263, figs. 2).—Supplementing a previous report (*E. S. R.*, 87, p. 767), fruit tree injury in 1942 proved to be of two types: (1) Bark killing on trunk, collar, and large crotches owing to immaturity of wood, and (2) wood injury resulting in blackheart. Though weather conditions were primarily responsible on peach, cherry, and apple, the first type occurred on soils or under management conditions indicating late growth in the fall. These were the most fertile soils, which were naturally moist. The contributory management practices were those that failed to supply a vigorously growing cover on the stronger soils in the fall. Blackheart occurred in peach trees subjected to -12° F. or lower. Serious injury was associated with trees making weak growth in 1941-42, on dry infertile soils or those made infertile by sheet erosion. Trees making moderately vigorous growth showed the best survival, and soils should be selected or managed to obtain that type of growth if winter injury is to be kept low.

**The maturation and discharge of ascospores of the apple scab fungus in Indiana and its significance in control of scab**, R. C. BAINES (*Indiana Sta. Bul.* 471 (1942), pp. 13, figs. 6).—On the basis of present findings it is deemed

reasonable to predict that mature ascospores of *Venturia inaequalis* will be present each spring when young leaves appear on the trees and that they will be discharged during rainy periods until some time after the calyx stage. Ascospores matured first in southern Indiana and progressively northward, dates varying with the season and climatic conditions. Discharge occurred over 8 weeks or more, and the proportion discharged by the calyx stage of fruit development depended on the frequency and duration of rains and the time required for the trees to pass through the early growth stages. The location of overwintering leaves in the orchard apparently had little effect on the date of ascospore maturity. Ascospore maturity dates on leaves of 11 apple varieties exhibited no significant differences.

**Peach-suture spot**, E. M. HILDEBRAND. (Cornell Univ.). (*Phytopathology*, 33 (1943), No. 2, pp. 167-168, fig. 1).—A new disease of unknown cause affecting only the fruit was found in a New York State Elberta orchard. The suggested name refers to the striking spot lesions in the suture region, readily distinguishable from red suture virosis because they become dry and corky with age. The lesions appear when the fruits approach maturity, are usually oblong in shape, and extend from the surface to the pit. Diseased fruits drop, and affected trees may be located by their presence on the ground.

**Stamen blight of blackberries**, S. M. ZELLER and A. J. BRAUN. (Oreg. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 2, pp. 136-143, figs. 3).—This disease, due to *Haplospheeria deformans* and first observed in Oregon on dewberries (1937) and on wild trailing blackberry (*Rubus macropetalus*), was found to infect the anther walls and form a pseudoparenchymatous envelope completely surrounding the pollen sac. Pycnidia formed thereon erupt on the surface ready to discharge coils of pycniospores when the flowers open. Between May and the following March infection takes place through the axillary buds. A perfect stage of the fungus has not been found. No control was afforded by dormant sprays (January-March) of bordeaux or lime-sulfur, but the latter applied in August gave indication of about 60 percent control. Commercial varieties affected in Oregon are Boysen and Young dewberries and Evergreen blackberries.

**Decline disease of raspberry**, S. M. ZELLER and A. J. BRAUN. (Oreg. Expt. Sta.). (*Phytopathology*, 33 (1943), No. 2, pp. 156-161, figs. 3).—This Cuthbert red raspberry disease, causing the decline of large areas on commercial plantings in the Willamette Valley, Oreg., presents no particular symptoms except a gradual dwindling in vigor of canes and roots along with some leaf rolling and fluting in late fall. In the greenhouse this leaf roll is characteristic throughout the season. The disease, considered due to a virus, has been transmitted by bud grafting but no insect vector has yet been found. *Minuor ruborum* is the suggested binomial, with *Rubus* virus 8 as the numerical designation.

**Strawberry leaf blotch**, H. WORMALD and H. B. S. MONTGOMERY (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 29 (1941), p. 44).—A strawberry leaf blotch, probably due to *Phyllosticta grandimaculans*, is reported for the first time in Great Britain.

**Red stele root rot of strawberries: Serious new disease curtails strawberry production**, D. CATION, C. A. BOYER, and C. W. ROBERTSON (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 233-242, figs. 2).—The *Phytophthora fragariae*-induced red stele, first reported for Michigan in 1937, is now well established and considered the most serious strawberry disease in that and other northern and eastern States. Pertinent information concerning it is here summarized. Because even long-period rotation is of questionable value, current control must consist in use of healthy stock on noninfested soil. Ultimate control will rest

largely on the development of resistant varieties, which it is expected will soon replace those now grown.

Witches' broom disease investigations.—III, Notes on the occurrence of witches' broom disease of cacao at River Estate, 1939-1942, R. E. D. BAKER (*Trop. Agr. [Trinidad]*, 20 (1943), No. 1, pp. 5-12).—Continuation of a series (E. S. R., 88, p. 494).

El "ojo de gallo": Enfermedad del cafeto [The "cock's-eye" disease of coffee], R. P. ROBÁ (*Nicaragua Min. Agr. y Trab. Bol.* 7 (1940), pp. [1]+14, figs. 5).—This spot disease of the leaves and berries, due to *Omphalia flava* and said to be one of the most injurious maladies of coffee in Nicaragua, is here described and discussed relative to its geographical distribution and propagation, the factors favoring it, and methods of control.

Preventing the bacterial oxidation of rubber, A. E. DIMOND and J. G. HORSFALL. (Univ. Nebr. and Conn. [New Haven] Expt. Sta.). (*Science*, 97 (1943), No. 2510, pp. 144-145).—The accelerators mercaptobenzothiazole and tetramethylthiuram disulfide (each by itself active against fungi) are intimately mixed with zinc oxide in the compounding of rubber. Tests here reported indicate that when compounded with zinc oxide the first becomes inactivated as a fungicide, whereas the second does not. It thus seems clear that when rubber is to be subjected to conditions favoring microbiological disintegration tetramethylthiuram disulfide is the accelerator of preference.

Progress report on soil applications of zinc sulphate in the control of rosette of pecan, A. O. ALLEN and H. E. HAMMAR. (U. S. D. A.). (*Tex. Pecan Growers Assoc. Proc.*, 21 (1941), pp. 63-70).—Results to date suggest very little benefit the same season from soil applications of  $ZnSO_4$  on alkaline, neutral, or slightly acid substrates but that heavier applications than have been generally used show promise of overcoming rosette on some soils. Results from use of sulfur and manure along with the  $ZnSO_4$  were encouraging and showed more promise than heavy applications of the salt alone, but further work is needed before recommendations can be made.

An improved method in the direct treatment of rosette with sulphate, A. WINKLER (*Tex. Pecan Growers Assoc. Proc.*, 21 (1941), p. 59).—A piece of iron pipe is inserted in the hole through which the  $ZnSO_4$  is applied, thus permitting re-treatments at any time.

Duration of the effect of zinc sulphate treatment on large, badly rosetted pecan trees, A. C. GOSSARD and H. E. PARSON. (U. S. D. A.). (*Southeast. Pecan Growers Assoc. Proc.*, 35 (1941), pp. 31, 33, 35-36).—Marked improvement in rosette symptoms for one or more years as compared with untreated trees followed soil applications (1) and tree injections (2) of  $ZnSO_4$ , being more rapid but less pronounced in the latter case. In (1), after 4-5 yr., the symptoms had gradually increased to a mildly rosetted condition. However, an apparent slow improvement of the untreated trees seemed to be a contributing factor in lessening the final differences between treated and control trees, possibly due to a liberation of small amounts of zinc from the oystershell meal used as a soil dressing. At the end of the experiment the injected (2) and control trees had attained about the same severity and quantity of rosette, differences being scarcely discernible.

Leaf variegations of perennial delphiniums, H. H. P. SEVERIN (*Hilgardia [California Sta.]*, 14 (1942), No. 10, pp. 571-582, pls. 2, fig. 1).—Variegations for which the names "golden-leaf" and "silver-leaf" are proposed proved to be seed-borne but nontransmissible by aphids (10 species tested) or by juice inoculations. Variegation was sometimes associated with calico or aster yellows infections (one or both) in the same plant, but although these infections were

readily transmitted the variegation was not. It is concluded that these variegations are not virus diseases.

**The susceptibility of perennial delphiniums to six viruses, H. H. P. SEVERIN** (*Hilgardia* [*California Sta.*], 14 (1942), No. 10, pp. 549-570, pls. 6, figs. 2).—Perennial delphinium was shown to be infected spontaneously with tomato spotted wilt, which ranks next in seriousness to aster yellows in the central-coastal regions of California, and also with a virus complex including spotted wilt and celery calico. Varieties and hybrids were experimentally infected with common and western cucumber mosaics (systemic types), tobacco ring spot (systemic) and ordinary tobacco mosaic (local). Orange larkspur (*Delphinium nudicaule*), a native perennial, was previously reported as a symptomless carrier of curly top (E. S. R., 76, p. 818), and Wrexham delphinium proved immune to it.

**The nature of the mosaic disease of bandakka (*Hibiscus esculentus* L.), M. FERNANDO and S. B. UDURAWANA** (*Trop. Agr. [Ceylon]*, 98 (1942), No. 1, pp. 16-24, pls. 2).—The evidence suggests that this okra disease is due to a virus, transmitted by budding but thus far not by seed.

**Viroses of annual larkspurs, H. H. P. SEVERIN** (*Hilgardia* [*California Sta.*], 14 (1942), No. 10, pp. 583-594, pls. 2).—Annual larkspurs (delphiniums) were shown to be spontaneously infected with California aster yellows, celery calico, and curly top, and were experimentally infected with western cucumber mosaic.

**Some virus diseases of *Stachytarpheta*, C. A. LOOS** (*Trop. Agr. [Ceylon]*, 98 (1942), No. 1, pp. 8-12, pls. 2).—Mosaic, rosette, and yellow vein banding are included.

**Additional records of violet scab, A. E. JENKINS. (U. S. D. A.).** (*Phytopathology*, 33 (1943), No. 2, pp. 168-169).—Violet scab (*Sphaceloma violae*) is reported from Massachusetts, Connecticut, North Carolina, Mississippi, and Texas. New susceptibles being *Viola jooi*, *V. priccana*, *V. vilmoriniana*, and white-flowered *V. odorata*.

**Phytophthora crown and root rot, P. A. MILLER. (Univ. Calif.).** (*Natl. Shade Tree Conf. Proc.*, 18 (1942), pp. 320-325).—On the sudden decline and death of various ornamental trees and shrubs caused by *Phytophthora* in the California coastal region, including a description of the symptoms and discussion of prevention and control.

**Fomes annosus and red cedar, J. K. MILLER** (*Jour. Forestry*, 41 (1943), No. 1, pp. 37-40).—Suppression of *Juniperus virginiana* from competition for light by overtopping tree species renders it susceptible to attack by this fungus. Little loss from *F. annosus* may be anticipated on suitable sites exposed to full sunlight.

**Taxonomy, distribution, and pathology of *Phomopsis occulta* and *P. juniperovora*, G. G. HAHN. (U. S. D. A. et al.).** (*Mycologia*, 35 (1943), No. 1, pp. 112-129, figs. 2).—The heightened interest in eastern red cedar (*Juniperus virginiana*) for conservation and ornamental plantings has focused attention on its diseases. Because of the close morphological similarity of the saprophyte *P. occulta* to the destructive nursery parasite *P. juniperovora* on this host, the distribution of the two fungi has been confused. In comparable wound inoculation tests in an unheated greenhouse, *P. occulta* proved unable to attack any of the 14 wildling cedar saplings used, corroborating similar tests on Arizona cypress and Chinese arborvitae; all 7 trees inoculated with *P. juniperovora* became infected. In cultures, neither the yellow color nor the flaming orange crystals of the latter fungus appeared in *P. occulta*, thus serving to differentiate the two species with overlapping spore size ranges. A detailed discussion is presented of the taxonomy, distribution, and pathogenicity of these related fungi. *P. occulta* is to be regarded as a secondary fungus on cedars following injury by other causes. *P. juniperovora* under natural conditions parasitizes only mem-

bers of the Cupressaceae (revised host list included) and, unlike *P. occulta*, its *Diaporthe* stage is unknown. There are 19 references.

**Powdery mildew of the coast live oak**, P. A. MILLER (Univ. Calif.). (*Natl. Shade Tree Conf. Proc.*, 18 (1942), pp. 358-366, figs. 3).—A progress report (E. S. R., 88, p. 359) summarizing 2 years' further study and observation by the author of the disease of *Quercus agrifolia* due to *Sphaerotheca lanestris*, and 3 years' control trials (pruning, spraying, and selection and propagation of resistant trees).

**Mimosa wilt—a major problem**, G. H. HEPTING and E. R. TOOLE (U. S. D. A.). (*Natl. Shade Tree Conf. Proc.*, 18 (1942), pp. 254-258).—This is an account of the present status of *Fusarium* wilt of *Albizia* spp., now known from North Carolina to Florida, and including a summary of experimental work by the authors. Some promise of resistance in individual trees was found.

**A canker of eastern pines associated with *Atropellis tingens***, J. D. DILLER (U. S. D. A.). (*Jour. Forestry*, 41 (1943), No. 1, pp. 41-52, figs. 7).—A twig- and branch-girdling canker caused considerable flagging in crowns of native and exotic pines in the eastern United States, 1933-34. Although formerly suspected as being an introduced disease, because first observed on exotic species (1932), later surveys indicated it to be widespread in the East, occurring on 17 pine hosts. The disease is primarily one of saplings, though all size classes may be attacked. The pine spittle bug (*Aphrophora parvella*) was ruled out as involved and the fungus *Atropellis tingens* shown to be the cause. The evidence, including 7 yr. of field observations, indicates that the damage has been minor, even in the epidemic seasons only an occasional suppressed seedling in an overstocked stand of natural reproduction being killed. A recurrence of the epidemic under favorable conditions may be expected, but no control measures are considered necessary.

**Importance of fungi and defects in handling Alaskan airplane spruce**, D. V. BAXTER and R. W. VARNER (Mich. Univ., School Forestry and Conserv. Cir. 6 (1942), pp. 35, pls. 9).—Prominent among woods valued for airplane stock is that of Sitka spruce (*Picea sitchensis*), and it is currently important that the output be increased and delivered in the best possible condition. To aid in carrying out these activities the authors discuss the occurrence of the species in Alaskan forests, the common fungi encountered thereon, the growth of certain of them in culture, a key for the identification in culture of certain northern North American fungi causing defects, and problems in handling airplane stock with recommendations pertaining thereto.

**Characteristics and significance of white floccose aggregates in the wood of western hemlock**, B. L. GRONDAL and A. L. MOTTET (Wash. Univ. [Seattle], Forest Club Quart., 16 (1942-43), No. 1, pp. 12-18, figs. 4).—These aggregates, occurring especially in the so-called "sinker" type of heartwood and here termed "floccosoids" bear only a remote resemblance to the white pockets due to *Trametes pini*, a fungus commonly attacking coniferous timber of various species. As a result of detailed microscopic examination and pathological and microchemical tests, it appears highly improbable that the presence of these floccosoids has any effect on the strength of the wood, and on the basis of all existing evidence wood containing them should be acceptable in all aircraft grades. A practical method of differentiating the floccosoids from the white specks or spots due to decay is given.

**Decay in Douglas fir cork and studies in the cultural identification of fungi causing decay in western hemlock and Douglas fir**, C. E. SELISKAR (Wash. Univ. [Seattle], Forest Club Quart., 16 (1942-43), No. 1, pp. 4-11, fig. 1).—Decay in Douglas fir bark, a rich source of valuable cork, occurs as

small hollow areas scattered throughout which might be mistaken for insect injury but which circumstantial evidence indicates is due to fungus infection. Besides bacterial contamination, four fungi—*Mortierella simplex*, *Dematium* sp., *Chalara* sp. (?), and an unidentified basidiomycete—were consistently isolated. The first three gave no indications of a causal relation, but the last appeared to be associated with the decay. Details of the further study on cultural identification of fungi causing wood rots in western hemlock and Douglas fir are discussed, including the general plan and some of the problems encountered.

**Principal decays of British hardwoods**, K. S. CARTWRIGHT and W. P. K. FINDLAY (*Ann. Appl. Biol.*, 29 (1942), No. 3, pp. 219–253, pls. 5).—The principal wood-rotting fungi on the more common broadleaved trees are listed with notes on their occurrence and relative importance, and the results of tests on natural resistance to them are tabulated. The principal diagnostic features of the more important fungi attacking ash, beech, elm, willow, and fallen hardwoods generally are also set forth in tables. Finally, detailed descriptions with further available information are given for 16 fungus species. There are over two pages of references.

**On *Fusarium equiseti* (CDA) Sacc. (= *Fusarium falcatum* App. et Wr.) causing a leaf-spot disease of *Eichhornia crassipes* Solms**, I. S. BANERJEE (*Jour. Dept. Sci., Calcutta Univ., n. ser.*, 1 (1942), No. 3, pp. 29–37, pl. 1, figs. 35).—Successful isolation from common water-hyacinth leaves and infections from culture are reported.

**An undescribed *Lagenidium* parasitic upon *Potamogeton***, V. M. CUTTER, JR. (Cornell Univ.). (*Mycologia*, 35 (1943), No. 1, pp. 2–12, figs. 21).—*L. mucoscheri* n. sp. is described as causing a hypertrophy of the root hairs on *P. spirillus*.

**Os nematóides e os meios usuais para o seu controle [Nematodes and usual methods of control]** J. SOARES BRANDÃO, JR. (*Bol. Min. Agr. [Brazil]*, 30 (1941), No. 7, pp. 9–15).—Lists of plants susceptible and resistant to root knot are included.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Food of some Utah birds**, J. S. STANFORD and G. F. KNOWLTON. (Utah Expt. Sta.). (*Auk*, 59 (1942), No. 4, pp. 580–581).—Brief records are given of the insect food contents of stomachs of 10 species of birds collected in Utah and examined during the season of 1941.

**College entomology**, E. O. ESSIG (*New York: Macmillan Co.*, 1942, pp. VII + 900, [pl. 1], figs. 308).—Following the first three chapters of this work, which deal, respectively, with metamorphosis, anatomy, and classification of insects, 33 orders are considered in as many chapters. A key (or keys), together with a list of selected references to the literature, accompanies many of the chapters, and a general list of handbooks, etc., relating to entomology is appended.

**[Contributions on economic entomology]** (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 955–963).—Contributions prepared for presentation at the annual meeting of the American Association of Economic Entomologists, abstracts of which are given, include: Azobenzene as a Control for Chiggers in Lawns, by D. M. DeLong and E. D. Witman; Insects Attacking Belladonna in Pennsylvania, by C. A. Thomas; The Mosquito Problem in North Dakota, by J. A. Munro and H. S. Telford; A Comparative Study of Several Methods of Sampling Adult Mosquito Populations, by C. B. Huffaker and R. C. Back; Ox Warble, *Hypoderma lineata* (de Villers), Control in Range Cattle, by M. A. Stewart; Capacity of Insects to Ruin the Protection Offered Foods by Various Types of Containers, by E. A. Back; The Tomato Russet Mite *Phyllocoptes destructor* Keifer—Its Present Status, by S. F. Bailey and H. H. Keifer; The Effects of Sulfur Residue Upon the Keeping

Qualities of Canned Tomato Products—a Preliminary Report, by G. M. List; Substitutes for Tartar Emetic and Brown Sugar in the Control of the Gladiolus Thrips, by F. F. Smith; The Insecticide Requirements of California Crops, by S. Lockwood; Laboratory Studies of Acrylonitrile, Chloropicrin, Methyl Bromide, and Other Fumigants Against the Bedbug, by H. H. Richardson; Toxicity of Alpha, Beta-Dibromo-Beta-Nitroethyl Benzene to Houseflies, by E. R. McGovran, M. S. Schechter, and J. H. Fales; Concentrated Spray Experiments, by L. P. Ditman, H. S. McConnell, and E. N. Cory; The Relative Resistance of *Periplaneta americana* L. and *Blattella germanica* L. to Pyrethrum Spray, by E. R. McGovran, J. H. Fales, and P. G. Piquett; Cause of an Infestation by *Tribolium confusum* of Rolled Oats Packaged in Three-Pound Cardboard Cartons, by E. A. Back; The Toxicity of Ethlde to the Firebrat and Three Species of Stored Grain Insects, by J. M. Grayson and E. W. King; The Present Status of Basic Copper Arsenate as an Insecticide and Fungicide, by H. A. Waters, D. M. DeLong, and E. D. Witman; Further Studies of Sulfur in Combination With Other Materials for the Control of *Empoasca* Leafhopper and Tarnished Plant Bug on Alfalfa, by G. L. McCall and D. M. DeLong; Reversals in Order of Effectiveness of Insecticides, by N. Turner; Factors Determining the Regression of the European Corn Borer (*Pyrausta nubilalis* Hbn.) in Quebec, by G. Maheux and G. Gauthier; The Significance of Growth Stages of Sweet Corn as Related to Infestation by the European Corn Borer, by R. L. Beard; The Ultimate Water Soluble Arsenic Value, by E. D. Witman, H. A. Waters, and E. R. Rothenich; Control of Aphids and Diamond-Back Moth Larvae on Collards With Rotenone-Nicotine Dusts, by H. G. Walker and L. D. Anderson; Ethylene Dichloride Treatments for the Control of the Immature Stages of the Japanese Beetle, by A. C. Mason and R. D. Chisholm; Treatment of Elm Logs to Prevent Bark Beetle Entry, Breeding, and Emergence, by D. P. Connola, L. E. Hagmann, and D. L. Collins; Developments in Research on the Bark Beetle Vectors of the Dutch Elm Disease Fungus, by C. W. Collins, R. R. Whitten, and R. T. Webber; The Application of Twig Clipping Supported by Certain Other Sanitary and Cultural Practices in the Control of the Oriental Fruit Moth, by G. E. Marshall; The Relation of Winter and Spring Temperatures to Injury of Peas by the Pea Aphid, by L. P. Ditman and E. N. Cory; Combination Rotenone-Nicotine Dusts for Pea Aphid Control, by J. H. Lilly; Tests on Bordeaux Mixture and Other Sprays for the Control of Japanese Beetle, by D. L. Collins and R. V. Nardy; Toxicity of 95 Synthetic Organic Chemicals to the Codling Moth, by E. D. Witman, B. C. Dickinson, H. A. Waters, and D. M. DeLong; A Simplified Method of Sampling Known Areas of Apple Leaves for Chemical Analysis, by F. H. Lathrop and B. E. Plummer; Stability of Basic Lead Arsenate With Spray Ingredients, by J. M. Ginsburg; The Economic Importance of the [Smaller] European Elm Bark Beetle, by E. P. Felt and S. W. Bromley; Some Factors Influencing Protective Stupefaction of the California Red Scale With Hydrocyanic Acid, by H. R. Yust, H. D. Nelson, and R. L. Busbey; The pH Values of the Alimentary Canal of Various Insects, by B. C. Dickinson and E. D. Witman; Experiments on the Control of *Limonius agonus* (Say) on Shade-Grown Tobacco in Connecticut, 1937-42, by A. W. Morrill, Jr.; Reduction of Flea Beetle Injury to Tomato Transplants by Treatment Prior to Setting, by T. C. Watkins and S. Logan; The Effect on Peach Trees of Ethylene Dichloride Emulsion as Used for Peach Tree Borer Control, by O. I. Snapp; Technique for Obtaining Accurate Exposure Times for Still and Movie Photomicrograph, by H. A. Waters; Lead Arsenate and Tricalcium Arsenate-Bentonite Combinations and Lead Arsenate-Zinc Sulfate-Summer Oil Emulsion Combinations as Sprays for the Control of Codling Moth, by R. L. Parker and P. G. Lamerson; Red Spider Mite [*Tetranychus telarius* L.] Control on Alfalfa in a Greenhouse by Certain New Organic Insecti-

cides, by R. L. Parker; Daily and Seasonal Behavior of Flies Around Unsprayed Cows as Shown by Hourly Fly Counts, by R. C. Smith; and *Sagaritis provancheri* (D. T.), an important Parasite of the Tobacco Budworm, by G. Wene.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 938-949, figs. 2).—Contributions presented (E. S. R., 88, p. 498) are: A Major Outbreak of the Southwestern Corn Borer in Kansas, by D. A. Wilbur, H. R. Bryson, and R. H. Painter (pp. 938-939) (Kans. Expt. Sta.); Cube and Nicotine in the Control of *Phyllotreta vittata discedens* Weise, by M. J. Janes (pp. 939-940) (Tex. Sta.); The European Corn Borer in Iowa, by H. M. Harris and J. M. Brindley (pp. 940-941); A Preliminary Report of a Critical Examination of the Roots of *Derris elliptica*, by F. A. Gunther and F. M. Turrell (p. 941) (Calif. Citrus Sta.); Seasonal Insect Food of the Brown-Shouldered Uta (Lizard) [*Uta stansburiana stansburiana*], by G. F. Knowlton, W. D. Fronk, and D. R. Maddock (p. 942) (Utah Sta.); Some Parasites of *Heliothis armigera* (Hbn.) in Texas, by F. F. Bibby (pp. 943-944) (Tex. Sta.); Effects of High Temperature on Several Household and Storage Grain Pests, by E. E. Kenaga and F. W. Fletcher (p. 944); A Two-Season Light Trap Study of Mosquitoes in Colorado, by M. T. James (p. 945) (Colo. State Col.); Rice Stinkbug [*Solubea pugnax* (F.)] as a Pest of Sorghums, by R. G. Dahms (pp. 945-946) (U. S. D. A. and Okla. Sta.); Armyworm Habit of *Heliothis armigera* (Hbn.), by C. F. Rainwater (pp. 946-947), Methyl Bromide Fumigation of Refrigerator Trucks, by H. C. Donohoe and C. H. Gaddis (p. 947), and Two Economic Species of Mites [*Eriophyes caryae* Keifer and *Paratetranychus viridis* Banks] on Pecan, by C. B. Nickless (p. 948) (all U. S. D. A.); and The Term "Inverted Spray Mixture," by J. Marshall (pp. 948-949).

[Insect investigations by the Arkansas Station] (*Arkansas Sta. Bul.* 428 (1942), pp. 36-41, 52-53).—A progress report (E. S. R., 88, p. 72) of work by W. J. Baerg and D. Isely, noting control of strawberry insect damage, spot dusting to control the boll weevil, control of corn earworm in sweet corn, and the control of rice field mosquitoes.

[Investigations in economic entomology by the Oklahoma Station]. (Partly coop. U. S. D. A.). (*Oklahoma Sta. Bien. Rpt.* 1941-42, pt. 1, pp. 54-61, figs. 6).—A progress report (E. S. R., 84, p. 781) noting safer methods for fumigating wheat bins, timing in relation to armyworm control in wheat, covering stubble for control of the brown wheat mite *Tetranychus tritici*, pest survey and insect control, location of apiaries, garden insect control, carriers of anaplasmosis, flatheaded apple tree borer control, phosphorus in relation to chinch bug damage on sorghums, testing barleys for chinch bug resistance, and cotton in relation to melon aphid abundance in cantaloup fields.

Insetos do Brasil [Insects of Brazil], A. DA COSTA LIMA (*Rio de Janeiro: Escola Nac. Agron.*, 1942, vol. 3, pp. 327, figs. 267).—This third volume (E. S. R., 85, p. 85) takes up the nine superfamilies of the order Homoptera, a bibliography accompanying each.

✓ The measurement of the effect of entomophagous insects on population densities of their hosts, H. S. SMITH and P. DE BACH. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 845-849, figs. 3).—The need of methods for measuring the quantitative effect of introduced entomophagous insects on the survival of their host populations is considered. The difficulty of excluding the introduced enemies from test plats appears to be one of the principal obstacles. Report is made of an experiment in which this was accomplished by the use of sleeves of fine-meshed cloth in such a way that the effect of the presence and absence of parasites on the survival of their host populations could be measured.

**Controlling insects in the home vegetable garden**, B. B. PEPPER (*New Jersey Stas. Cir.* 445 (1942), pp. 17).—A practical account.

**Recommendations for control of tomato insects**, W. W. STANLEY and S. MARCOVITCH (*Tennessee Sta. Cir.* 82 (1943), pp. [2]).

**Orchard insects of the Pacific Northwest and their control**, E. J. NEWCOMB (*U. S. Dept. Agr. Cir.* 270, rev. (1942), pp. 80, figs. 83).—A revision (*E. S. R.*, 70, p. 358).

**The control of insects infesting dried fruits**, W. BURNS BROWN and A. E. H. HIGGINS (*London: Dept. Sci. and Indus. Res.*, 1942, pp. [3]+I+23, figs. 8).

**Insect survival in drying grain**, M. D. FARRAR and R. H. REED. (*Ill. Nat. Hist. Survey and Univ. Ill.*). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 923-928 fig. 1).—A determination was made of lethal drying conditions for seven species of insects in their natural breeding medium, namely, angoumois grain moth and rice and granary weevils in ear corn and the lesser grain borer, confused flour beetle, flat grain beetle, saw-toothed grain beetle, and rice and granary weevils in wheat. Higher temperatures were found to be more destructive to all insects than lower temperatures, as were higher humidities and longer drying periods. "The rice and granary weevils were killed at lower temperatures, lower humidities, and shorter times of exposure than were the other species. The confused flour beetle and flat grain beetle adults were more resistant to drying than the rice or granary weevil and less resistant than the saw-toothed grain beetle. The adult saw-toothed grain beetle was less resistant than the angoumois grain moth, which in turn was less resistant than the adult lesser grain borer. Insects were more easily killed in ear corn than in shelled corn, wheat, or barley because the large air spaces permitted rapid movement of the air. The tendency for air to seek channels through a mass of grain or ear corn may result in differences of as much as 50° in the temperature within a distance of 2 to 4 in. The commercial drying of hybrid seed corn at dry bulb temperatures of 105° to 110° and wet bulb temperatures of 70° to 80° would not kill the common insects that infest stored grain."

**Insects infesting house plants.—II, Insects and allies of insects infesting the soil**, E. I. McDANIEL (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 2, pp. 242-245, figs. 3).—A continuation of this account (*E. S. R.*, 88, p. 656.)

[Contributions on shade tree insects] (*Natl. Shade Tree Conf. Proc.*, 17 (1941), pp. 108-118, figs. 4).—Among the contributions here presented are: The Outstanding Insects of Shade Trees in Maryland in 1941, by E. N. Cory (pp. 108-109) (*Univ. Md.*); and Control of the Pine Sawfly *Neodiprion sertifer* Geoff. With Concentrated Lead Arsenate Sprays, by C. C. Hamilton (pp. 110-116) (*N. J. Expt. Stas.*).

**Isolation of *Ceratostomella ulmi* from insects attracted to felled elm trees**, T. H. JONES and C. S. MOSES. (*U. S. D. A.*). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 2, pp. 77-85, figs. 2).—Experiments were conducted from 1936 to 1939 to ascertain what species of insects carried the Dutch elm disease fungus (*C. ulmi*) and what percentage of each species was contaminated with the organism. Insects attracted to felled healthy American elms at several locations in New Jersey and New York were collected, identified, and cultured. *C. ulmi* was found most frequently in two species of elm bark beetles which are the most important insect carriers of the disease organism, namely, the smaller European elm bark beetle and the native elm bark beetle. This organism was isolated in a few cases from four other beetles, namely, *Xylobiops basilaris* (Say), *Conotrachelus inaglypticus* (Say), *Xylosandrus germanus* Bldfd., and the red elm bark weevil. *C. ulmi* was isolated from 6.9, 5.8, 7.7, and 5.7 percent of the smaller European elm bark beetles and from 4.3, 2.4, 3.3, and 0.7 percent of the native elm bark

beetles cultured in 1936, 1937, 1938, and 1939, respectively. The percentage of these two elm bark beetles contaminated with *C. ulmi* varied considerably at different locations in the same year and at the same location in different years.

**Current contributions on insect control, II** (*New York State Sta. Bul.* 703 (1943), pp. 64, figs. 9).—Included in this second series (E. S. R., 86, p. 651) are the following: The Control of the Common Red Spider [*Tetranychus bimaculatus* (Harvey)] on Lima Beans, by H. C. Hockett (pp. 5-7); Observations on the Economic Importance and Control of the European Chafer [*Amphimallon majalis* Razoum], by F. L. Gambrell (pp. 8-13); Rotenone for Apple Maggot Control (pp. 13-14) and Tank-Mixed Oil Sprays for European Red Mite Control (pp. 51-55), both by R. W. Dean; Experiments With Milky Disease for the Natural Control of the Japanese Beetle (pp. 14-17) and Insecticides for Peachtree Borer Control (pp. 62-63), both by E. H. Wheeler; An Improvement in the Nonresidue Apple Spray Schedule (pp. 17-18), Spreaders for Codling Moth Sprays on Apple (pp. 36-38), and The Effect of Summer Sprays on San Jose Scale Control on Apple (pp. 63-64), all by S. W. Harman; Substitutes for Mercury Salts in Cabbage Maggot Control, by H. Glasgow (pp. 18-20); A New Apple Leafroller [*Pseudezen-tera mali*], by P. J. Chapman and D. E. **"Natural" control of insects** (*Farm Res.* [New York State Sta.], 9 (1943), No. 1, p. 19).—A practical account.

**Fluorine compounds useful in the control of insects**, S. MARCOVITCH and W. W. STANLEY (*Tennessee Sta. Bul.* 182 (1942), pp. 46, figs. 25).—A review of the experimental work since 1924 with fluorine compounds, especially sodium fluoride, sodium fluosilicate, and cryolite. Sodium fluoride is valuable for the control of cockroaches, chicken lice, silverfish, and ants. Sodium fluosilicate is useful as a mothproofing agent and for the control of grasshoppers, crickets, cutworms, and certain weevils. The author states that "the virtues of cryolite as an insecticide lie in the fact that it will not injure foliage nor result in soil poisoning. In its effect on insects, cryolite is in the same zone of toxicity as lead arsenate. For certain insects, cryolite is specific and more toxic than magnesium arsenate or calcium arsenate." A large quantity of cryolite is used annually for codling moth control in the Pacific Northwest. Cryolite is also used for control of orange worms, the walnut husk fly, Mexican bean beetle, tomato fruitworm, flea beetles, cabbageworms, cranberry insects, blister beetles, and cucumber beetles. The relative toxicities of these three compounds to lower and higher animals are discussed.

**Relative effectiveness of several rotenone-containing insecticides against various insects, F. S. ARANT.** (Ala. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 873-878).—Report is made of laboratory and field tests of commercial samples of derris, timbo, and cube and samples of powdered *Tephrosia* roots against several species of insects. Derris and *Tephrosia* were more effective than *Lonchocarpus* of the same guaranteed rotenone content applied against a number of important vegetable pests.

**Deposits of insecticidal dusts and diluents on charged plates, G. F. MACLEOD and L. M. SMITH.** (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 66 (1943), No. 2, pp. 87-95, figs. 4).—Deposits of materials on positively and negatively charged plates were measured. Powders of plant origin in general gave heavy deposits on the negatively charged plate, while diatomites and clays gave heavy deposits on the positively charged plate. Other materials were variously distributed. The ratio of deposits was influenced by the material of which the outlet tube was constructed. Increasing the length of the outlet tubing increased the major deposit of any given material up to a maximum point beyond which no further increase or decrease was apparent. Adding 1 percent of one powder to another increased the major deposit in four out of eight cases. Deposits resulting from a mixture of two powders could not be predicted from a study of each of the component materials.

**Season nears end for the application of winter sprays, C. LYLE** (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, p. 8).—A practical account.

**Reduced spray concentrations for aphid and bud moth, F. Z. HARTZELL** (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 11, 15).—A practical account as to possible economies.

**Cumulative index to service and regulatory announcements, Nos. 1 to 149, inclusive (1914-41), Bureau of Entomology and Plant Quarantine, M. A. THOMPSON** (*U. S. Dept. Agr., Bur. Ent. and Plant Quar.*, 1942, pp. II+89).

**Effects of infra-red irradiation on the American cockroach, G. F. MACLEOD.** (Univ. Calif.). (*Pests*, 10 (1942), No. 7, pp. 22-23).—Using an incandescent lamp capable of producing and focusing a large amount of infrared radiation, adults of the American cockroach were killed by exposure of the ventral surface to radiation from this lamp at a distance of 18 in. for a period of 2.5 to 4 min. Twice this dosage was required to kill adults when treated on the dorsum. None of the cockroaches was killed when irradiated through a water screen which removed a large part of the infrared rays. All attempts to kill insects on plants have resulted thus far in injury or death of the plants before the insects were killed.

**The activating effect of pyrethrum upon the German cockroach, J. M. HUTZEL.** (Ohio State Univ. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 929-933, figs. 4).—A description is given of four methods employed to record the initial effect of pyrethrum on the German cockroach. The results indicate that pyrethrum is unique in its activating effect upon this insect. No other insecticide tested, including those containing N-butyl carbitol thiocyanate, rotenone, or nicotine, caused similar violent reactions. The activating effect of pyrethrum is of practical value because sublethal doses will impel the roaches to desert their hiding places and become exposed to lethal doses. In applications of pyrethrum dusts the reaction is such that the roaches drag their abdomens and otherwise increase the amount of toxicant adhering to their bodies.

**Action of pyrethrum upon the German cockroach, J. M. HUTZEL.** (Ohio State Univ. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 933-937, fig. 1).—This further contribution (see above) presents the results of an investigation

of the factors influencing the appendicular reactions (excitation, convulsions, and paralysis) of pyrethrum-treated German cockroaches by means of kymograph recordings. The results strongly suggest that excitation and paralysis of the German cockroach depend upon the rate of diffusion of the pyrethrins through integumentary secretions as influenced by the dose, concentration, and viscosity of the solution of the insecticide. The ventral surface of the cockroach is covered by an oily film which is present in sufficient quantity to moisten particles of pyrethrum powder applied to that area. In this manner the pyrethrins are enabled to diffuse from the particles and affect the insect. Pyrethrum affects the nervous system, since its activating effect upon the legs could be blocked by severing the nerve cord between the thorax and the point of application on the abdomen. This evidence is in accord with that of other investigators who were able to demonstrate cellular degeneration in the ganglia and connectives of pyrethrum-treated insects. The initial excitatory effect of pyrethrum upon the German cockroach appears to be the result of the stimulation of successive sensory endings in the integument. The time of onset of final paralysis appears to depend upon the speed with which the pyrethrins are spread to the thorax and their subsequent inactivation of the thoracic ganglia.

**An international termite exposure test**—[eleventh, twelfth, and thirteenth progress reports], G. M. HUNT and T. E. SNYDER. (U. S. D. A. coop. Univ. Wis.). (*Amer. Wood-Preservers' Assoc. Proc.*, 36 (1940), pp. 378-392; 37 (1941), pp. 379-392; 38 (1942), pp. 450-462).—These reports (E. S. R., 82, p. 219) record the results obtained from wood specimens treated with various chemicals and exposed to the activities of termites and decay.

**Effect of the addition of sulfonated oil on the toxicity of cube and derris to plant bugs**, R. A. FULTON and N. F. HOWARD. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 867-870, fig. 1).—Laboratory tests with the harlequin bug and the squash bug in which certain natural and sulfonated vegetable oils were used in combination with derris or cube indicate that the sulfonated oils are equal or superior to their natural counterparts in toxicity to these insects. In tests with the harlequin bug each oil used increased the toxicity of derris very significantly. Sulfonated olive and soybean oils appeared outstanding. In tests with the squash bug the addition of acetone to natural or sulfonated oil-cube sprays significantly increased their toxicity. Without acetone, sulfonated peanut oil-cube spray was superior to cube sprays containing sulfonated soybean or grapefruit seed oils. Injury to cucurbits and crucifers may result from the application of oil, but sulfonated oils are less injurious than emulsified natural oils.

**Insecticidal tests for field control of *Lygus* bugs in seed alfalfa**, C. J. SORENSON. (Utah Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 884-886).—Experiments conducted in 1933 and from 1937 to 1941 with insecticides have shown that other methods than the use of insecticides will have to be employed or developed for the current prevention and control of *Lygus* bugs in alfalfa-seed fields.

**Etude sur la biologie de *Dysdercus supersticiosus* F. (Hemiptera)** [A study of the biology of *Dysdercus supersticiosus* F. (Hemiptera)], J. M. VREYDAGE (*Inst. Natl. Etude Agron. Congo Belge Pubs., Sér. Sci., No. 24* (1941), pp. 19, figs. 3).

**The use of cyanide in controlling the root form of the woolly apple aphid**, C. F. SMITH. (N. C. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 908-910).—The results of tests made on the control of the woolly apple aphid and tree tolerance to sodium cyanide, carbon disulfide, and dichloroethyl

ether in 1940 and 1941 and the injury caused to aphid-free apple seedlings treated with these chemicals are summarized in tables. Injury occurred when more than 1 gm. of sodium cyanide was used per tree or in less than a quart of water. Also, good control was obtained with as little as 0.5 gm. of cyanide per tree in a pint of water in 1940 and 1941, and 0.1 gm. gave good control in 1940. In using cyanide it is believed the quantity of water and cyanide needed will depend on the moisture content of the soil and the degree of infestation, less water and cyanide being needed in moist situations where the infestation is light and more water and cyanide in the dry situations where the infestation extends over all the roots. Enough water and cyanide should be used to carry the cyanide to the lowest aphids on the roots. The results indicate that sodium cyanide will not injure young healthy apple seedlings unless more than 1 gm. is used per tree. Carbon disulfide in water is fairly safe at the concentrations used, but it does not give satisfactory control. Young apple seedlings seem quite susceptible to dichloroethyl ether at the concentrations used. Many more of the root hairs were injured in cases marked "slight injury" than was the case with carbon disulfide or sodium cyanide. Mention is also made of several materials tested that proved unsatisfactory.

**New materials for control of the mealy plum aphid, L. M. SMITH and C. A. FERRETS** (*California Sta. Bul. 671 (1942), pp. 30, figs. 2*).—Dinitro-*o*-cyclohexylphenol and sodium dinitro-*o*-cresolate were studied extensively, and both showed promise as winter sprays for the destruction of mealy plum aphid eggs and some scale insects in certain combinations. Neither compound, however, was effective against the Italian pear scale, and both injured cover crops. Trees were not damaged by dormant applications, but severe injury resulted if these materials were applied to trees which were starting to bloom. In special cases early-fall applications of dinitro phenols and cresols, without oil, showed interesting possibilities.

**A physiological difference in the two races of red scale and its relation to tolerance to HCN, H. J. QUAYLE.** (*Calif. Citrus Expt. Sta.*). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 813–816, figs. 2).—In this further contribution (E. S. R., 79, p. 656) reference is first made to the finding of Hardman and Craig (E. S. R., 86, p. 218) that in the time of closure of the spiracles there is an observable physiological basis for differentiating the resistant and nonresistant scales. However, the facts that the differential in tolerance is noted in a fumigation exposure of 2.5 min. (before there is any closure in either strain), as well as at other exposures up to and including 2 hr., that it occurs independently of stupefaction or differences in temperature, and that there is the possibility of the spiracles not functioning as claimed during at least a part of the molting process do not appear to support the longer period of closure of the spiracles in one strain as accounting for such differential.

**Reaction of resistant and nonresistant strains of California red scale to fumigation with HCN, H. R. YUST, R. L. BUSBEY, and H. D. NELSON.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 816–820).—Report is made of a study of the effect of pretreatment, treatment, and posttreatment temperatures and prefumigation with sublethal dosages on the susceptibility of resistant and nonresistant strains of the California red scale to fumigation with hydrocyanic acid. "When scales were preconditioned and postconditioned for 4 hr. at the treatment temperatures, the kill of the resistant scales in the second molt and in the mature female scale and of the nonresistant scales in the second molt was increased by lowering the temperatures, but the kill of nonresistant mature female scales was not influenced by the treatment temperature. When mature female scales were preconditioned for 18 hr. instead of 4 hr., the kill of the

resistant scales was increased by lowering the temperatures, and the kill of the nonresistant scales was decreased. In fumigations of scales in the second molt at both 59° and 77° F. preconditioning at 59° increased the kill of both strains, but the effect of the pretreatment temperature was produced more quickly in the nonresistant strain than in the resistant strain. In fumigations of mature female scales at 59° short preconditioning periods of 2 or 4 hr. significantly increased the kill of resistant scales but did not influence the kill of nonresistant scales. The kill of resistant scales was influenced more by the temperature after fumigation than was the kill of nonresistant scales. In the second molt the kills of both strains were decreased by prefumigation with sublethal dosages, but the differences were more marked with the resistant strain. In the mature female stage the kill of resistant scales was decreased significantly by prefumigation in treatments at 59°. The kill of the nonresistant scales was not changed by prefumigation 1 hr. before the final fumigation when the preconditioning period was 4 hr., but when the preconditioning period was 18 hr. the kill was significantly increased by prefumigation."

**Factors influencing results of laboratory fumigation of California red scale with HCN.** H. R. YUST and L. B. HOWARD. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 821-824).—Report is made of laboratory fumigation work conducted to determine the cause of variations that have resulted in the use of hydrocyanic acid gas against the California red scale. "The scales were reared on lemon fruits in the laboratory and fumigated at 77° F. and 65 percent relative humidity. Better kills were obtained on lemons that were slightly soft than on those that were firm and turgid. At times the kill on fruits from different groves was markedly different, although the appearance of the fruits was the same. On the same fruits mature female scales that were fused together were a little more difficult to kill than those that were not touching other insects. Frequently, difference in age within the stage affected the kill, probably owing to a difference in degree of development. An increase of 18° in the temperature after fumigation favored increased mortality of scales in the second molt and of mature females, but the two stages reacted differently to a drop of 25° after fumigation. The scales in the second molt developed more slowly after a high kill than after a low kill; therefore the total mortality could not be determined so quickly after a high kill."

**Spray-fumigation experiments on California red scale.** D. L. LINDGREN and R. C. DICKSON. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 827-829).—In laboratory tests in which the California red scale was treated with oil spray and with hydrocyanic acid gas fumigation, used separately and in combination, scales which survived the oil spray treatment did not prove to be more susceptible to fumigation than unsprayed scales. The length of the interval between the spray treatment and the fumigation treatment does not seem to be an important factor. The second-molt and early-gray stages of red scale, which are the most likely to survive the fumigation, are relatively easy to kill by the oil spray. The late-gray and adult insects, which are difficult to kill by oil spray, are comparatively easy to kill by fumigation. From the results of the experiments it appears that the satisfactory control of California red scale by the use of a combination of oil-spray and fumigation treatments is due to the additive effect of the two treatments and to the complementary nature of the kills resulting from the separate treatments. The order in which the treatments are given has no significant effect on the combined results, but the factors of climate and tree tolerance indicate that, in the field, the spray should usually precede the fumigation.

**Fumigation of yellow scale with HCN under laboratory conditions.** H. R. YUST, H. D. NELSON, and R. L. BUSBEY. (U. S. D. A.). (*Jour. Econ. Ent.*, 35

(1942), No. 6, pp. 825-826).—It was found in hydrocyanic acid fumigation with the yellow scale, reared in the laboratory on lemon fruits under controlled conditions, that female scales were considerably less susceptible to fumigation than those in the second molt. Under similar conditions California red scales in the second-molt stage were more difficult to kill than the mature females. In the second-molt stage yellow scales and California red scales of the nonresistant strain were about equally susceptible to hydrocyanic acid, but in the mature stage yellow scales and California red scales of the resistant strain were equally susceptible. As with the California red scale, the mortality of yellow scales decreased as the temperature at the time of fumigation was increased. Prefumigation with sublethal dosages of hydrocyanic acid caused in practically all cases a considerable lowering of the mortality of the yellow scale in both the mature female and second-molt stages exposed immediately thereafter to a lethal concentration. Yellow scales from stocks obtained in southern California were more difficult to kill than those from stocks obtained in central California.

**Biological observations on the citricola scale and its parasites, S. E. FLANDERS.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 830-833).—A study of the host plants and parasites of the citricola scale in California has shown this serious pest of citrus in the more arid regions of the State to be better adapted to hackberry (*Celtis* spp.) than to citrus. It has been found on hackberry only in or near areas of infested citrus. Citricola scale is known to occur outside of California only in Japan, where it is not a pest of consequence. Hackberry occurring in Japan, China, and Australia appears to be free from citricola scale. In Japan citricola scale is parasitized by *Metaphycus orientalis* Comp., *Coccophagus yoshidae* Nakayama, *C. japonicus* Comp., *C. hawaiiensis* Timb., and *Anicetus annulatus* Timb. In California it is attacked by *M. luteolus* Comp., *M. stanleyi* Comp., *M. helvolus* Comp., *C. lycimnia* (Walk.), and *C. scutellaris* (Dal.).

**Life history and habits of the potato flea beetle in western Nebraska, R. E. HILL and H. D. TATE.** (Nebr. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6 pp. 879-884, figs. 4).—In work in the potato-growing section of western Nebraska it was shown that a relatively high percentage of adult potato flea beetles were able to survive the winter of 1940-41 in soil covered with debris or crop residue such as potato vines. The survival ranged from 34.5 percent in soil covered with potato vines to 8.3 in alfalfa stubble. Two complete generations of the potato flea beetle developed during the season in the insectary. On the basis of the life history data presented it is evident that the larvae of the first generation develop largely in early-planted potatoes and the second generation principally in the late plantings. This has led to the conclusion that elimination of the early potato crop, including those plantings up to about June 10 (at present a relatively small proportion of the total acreage in western Nebraska), would materially reduce the likelihood of serious potato flea beetle injury in the area.

**Dichloroethyl ether for control of the sugar-beet wireworm, M. W. STONE.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 860-866).—The findings of Campbell and Stone (*E. S. R.*, 77, p. 65) and of Pepper (*E. S. R.*, 83, p. 377) led to the further investigation of dichloroethyl ether as a soil insecticide for the sugar beet wireworm. In the work here reported upon, conducted at Downey, Calif., in 1937, 1938, and 1939, the treatment of bait rows with concentrations of 0.2 to 1.2 oz. of dichloroethyl ether per 100 gal. of water at rates of 4 to 6 gal. of solution per foot of row resulted in wireworm mortalities of 81 to 100 percent. The addition of small quantities of emulsified dichloroethyl ether directly to tap water resulted in high mortalities of wireworms in cages

placed in trenches at different depths and distances from point of application. Similar results were obtained when potatoes and corn planted in furrows were treated with 3.4 and 5.1 oz. of dichloroethyl ether per 100 gal. of water at rates ranging from 1 to 3 gal. of solution per foot of row. There was no injury or retardation in the growth of these plants or of sugar beets and onions. The root systems of newly set tomato plants were affected by one application of 7- and 10-oz. concentrations of dichloroethyl ether per gallon of water, but after 2 mo. there was no difference in size between the treated root systems and those receiving water only. Wireworms were both repelled and killed by application of a mixture of fertilizer and sawdust treated with dichloroethyl ether to seed pieces at the time of planting. The wireworm population of small plats was reduced 21 to 65 percent by applications of weak concentrations of dichloroethyl ether in irrigation water carried to furrows or on the soil surface.

**Laboratory propagation of two predators of the mountain pine beetle,** G. R. STRUBLE. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 841-844, fig. 1).—In experiments with the green trogositid and the red-bellied clerid beetles (*Tennochila virscens* (F.) and *Enoclerus sphgeus* (F.)), thought to be important predators of the mountain pine beetle, it was shown that they may be reared under artificial conditions from egg to adult in the laboratory.

**Fumigation of small land areas for control of white-fringed beetles,** E. M. LIVINGSTONE and G. R. SWANK. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 919-922, figs. 3).—Experiments conducted in the vicinities of Monroeville, Ala., and Gulfport, Miss., during the period 1939-41 have shown that dosages of 4.7 cc. of methyl bromide would give complete mortality of all stages of the insects at an exposure of 3.75 days when the soil temperature is between 62° and 89° F. and at an exposure of 6 days when the temperature is between 45° and 62°. The results of tests with carbon disulfide indicate that complete mortality may be expected with a 3- to 4-day exposure if the temperature ranges from 80° to 87° F. At lower temperatures none of the exposures tested consistently killed all the insects.

**Biology of *Cylindrocopturus furnissi* Buchanan on Douglas-fir,** R. L. FURNISS. (U. S. D. A. et al.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 853-859, fig. 1).—Report is made of a detailed study, largely from 1938 to 1941 and chiefly at La Grande, Wash., of *C. furnissi*, a minor weevil pest of naturally established Douglas fir reproduction in western Washington and Oregon and northwestern California.

**Effectiveness of derris and cube in pickleworm control,** F. S. ARANT. (Ala. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 870-872).—In previous experiments (E. S. R., 84, p. 648; 86, p. 74) it was shown that derris-talc dusts containing 1 percent rotenone were effective in controlling the pickleworm under favorable conditions. In the present studies it was found that during a period of frequent rainfall 1 percent rotenone mixture of derris, talc, and flour did not give satisfactory control when applied to cantaloups at 10- and 15-day intervals; when applied at 5-day intervals the mixture gave 61-percent control. "This treatment was only two-thirds as effective as in previous years during more favorable weather conditions. Pickleworm infestation was extremely heavy in late cantaloups grown adjacent to plats of earlier melons. Derris and cube dusts containing 1 percent rotenone did not reduce the infestation materially until the dosage was increased to 20 lb. per acre per application. Twelve dustings at the average rate of 17.5 lb. per acre did not give practical control, although worm-free melons were matured at the rate of 750 to 2,080 per acre on the dusted plats as compared with none on the checks. Derris was more effective than cube. Cuproclde incorporated into one of the dust mixtures resulted in healthier

plants and higher yields than were obtained on plats not dusted with Cuprocydide. Ten applications of 1 percent rotenone dust applied at 5-day intervals at the rate of 12.5 lb. per acre gave satisfactory control of the pickle in cucumbers during a period of favorable weather. Derris gave 93 percent control and cube 79 percent."

**Time relationship of spring brood codling moth entry and subsequent worm entry**, R. L. WEBSTER and W. J. O'NEILL (Iowa Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 806-809, figs. 2).—Bait trap records of moth catch during the years 1939, 1940, and 1941 in the Wenatchee Valley of Washington are reported upon. The shortest time interval between the peak of moth catch and that of worm entry was 9 days in 1940, when the mean maximum temperature for this period was 81.7° F. The longest time interval was 29 days in 1939, from the first high peak May 12 to the peak of worm entry June 10. The mean maximum temperature for this period was 75°. Two main peaks occurred in the moth catch in addition to minor peaks. The maximum time difference in days is figured from the earlier peak. Mineral oil at ovicidal concentrations probably was of little value in the second cover spray in 1939 and 1941, but of great value in 1940. Delayed until the third cover spray in 1940, mineral oil would have had little value as an ovicide since the third cover was not applied until some days after the peak of worm entry. On the other hand, oil in the third cover in 1939 and in 1941 would have served well as an ovicide, since these applications were made well before the peak of worm entry.

**Spreaders in codling moth sprays**, L. T. GRAHAM and C. H. RICHARDSON. (Iowa Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 911-914).—The findings reported have shown that under Iowa conditions the effectiveness of codling moth sprays is not improved by the addition of soybean flour or lime-casein spreaders. No advantage was detected from the use of a sodium oleyl sulfate-resin spreader-sticker, although the data suggest that some benefit might be gained from it. Modification of the physical properties of a lead arsenate spray may not be reflected in improved codling moth control. A list of 41 references to the literature cited is included.

**Toxicity of nicotine compounds to newly hatched codling moth larvae**, R. HANSBERRY. (Cornell Univ.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 915-918).—The results of tests of 31 compounds of nicotine against newly hatched codling moth, both with fresh and weathered deposits, are reported in table form. Water-soluble compounds, with the exception of nicotine sulfate, gave poor kills of larvae both before and after weathering. Most insoluble compounds gave high kills with fresh deposits, but the coarser crystalline materials lost much of their effectiveness during weathering. Fine powders which were water resistant lost comparatively less toxicity during weathering. Since these materials were used without supplements, many of them may be improved by fine grinding, controlled precipitation, or the use of supplements. Fixed nictines were always more toxic than soluble materials, indicating that nicotine compounds kill newly hatched larvae primarily by stomach poison action, since it has been shown previously that fixed compounds are not toxic as contact agents. The best material, nicotine cuprocyanide, permitted only 8-percent entries in fruit sprayed with 0.5 lb. to 100 gal. and artificially weathered with 1 in. of rain compared to 44-percent entries in fruit sprayed with 3 lb. lead arsenate per 100 gal. and weathered under the same conditions.

**Survival, weight, and location of European corn borers feeding on resistant and susceptible field corn**, L. H. PATCH. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 66 (1943), No. 1, pp. 7-19, figs. 3).—Different plantings within two seasons of two single-cross hybrids of field corn, borer-resistant Ill. Hy × R4

and borer-susceptible III. A  $\times$  Ind. TR, were made at Toledo, Ohio, and infested by hand at different stages of plant development with equal numbers of egg masses of the European corn borer. The number of mature borers per plant on plants on which the borers hatched within 14 days of pollen shedding showed a pronounced increase over the number on plants in an earlier stage of development. In 1936 the number of mature borers in Hy  $\times$  R4 as a percentage of the number in A  $\times$  TR increased from 38 to 48 percent as the time between borer hatching and pollen shedding decreased from 38 to 14 days and then increased sharply to 86 as the interval decreased to 2 days. Within about 14 days of pollen shedding the relative availability of the tassel buds for feeding accounted for some of the difference in borer population between the two hybrids. In 1937 in A  $\times$  TR, 51 percent of the borers 4 days old were in the tassels 14 to 17 days before the plants shed pollen as compared with 5 percent in Hy  $\times$  R4, whose eclosion of tassels was delayed. Most of the differentiation in the borer population between the two hybrids occurred before the borers were 4 days old. From 18 to 46 days after hatching the borers in Hy  $\times$  R4 weighed 66 percent as much as those in A  $\times$  TR in the early plantings in 1937 and 81 percent as much in the late plantings. When 57 days old the borers in Hy  $\times$  R4 weighed more than 90 percent as much as the borers in A  $\times$  TR. The character of the feeding areas on the leaves and the excrement of the larvae also indicated that borer-resistant Hy  $\times$  R4 is a less suitable food for the borers. The relative locations of the borers in the two hybrids are given for different ages of the borers and the plants.

*Goniozus indicus* Ash., a natural enemy of the sugarcane white moth borer *Scirpophaga rhodoproctalis*, M. C. CHERIAN and P. ISRAEL (*Jour. Bombay Nat. Hist. Soc.*, 43 (1942), No. 3, pp. 488-493).—The biology of a bethylid parasite (*G. indicus*) of *S. rhodoproctalis* is reported upon.

**Hibernation of the corn earworm in the central and northeastern parts of the United States**, R. A. BLANCHARD. (Coop. expt. stas.). (*U. S. Dept. Agr., Tech. Bul.* 838 (1942), pp. 14, fig. 1).—Corn earworm larvae that mature after the middle of October are unable to enter hibernation in the Central and Northern States. The period from the middle of September to early in October is apparently the optimum time for larvae to enter the soil and hibernate successfully. Moth emergence extended from the second week in May to the last week in June, which is approximately the same time as under field conditions. Lack of survival at many of the points of observation might be due to length of exposure. Some mortality in hibernating forms was caused by diseases, earthworms, ants, nematodes, carabid beetle larvae, moles, rodents, and growing plant roots. Factors affecting hibernation indirectly were time of planting, rate of maturity of the corn, and time of the first frost in the fall. Cultural methods for destruction of hibernating earworms are recommended only for abandoned cornfields. Migrations from the South are suggested as the source of infestations found in the northern parts of the United States.

**The biology of *Theobaldia inornata* Williston in captive colony**, W. B. OWEN. (Univ. Wyo.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 903-907).—The author has found that the mosquito *T. inornata* can be easily established as a laboratory colony and appears to be well adapted for captive rearing. Although the larvae may be cultured by feeding them Pabulum, Purina Dog Chow, and other proprietary products, the most satisfactory method of rearing is in a semi-balanced aquarium supporting their natural food. At a temperature range of between 60° and 70° F. a new generation can be obtained in about 30 days. Blood feeding is necessary for normal egg laying. The average number of eggs produced by 14 vigorous females was 700.79. Approximately 98 percent of the eggs

laid by captive females were fertile. The average length of adult life for vigorous females was 95.79 days.

**A method of estimating reduction in yield of wheat caused by hessian fly infestation.** C. C. HILL, E. J. UHNE, and J. S. PINCKNEY (*U. S. Dept. Agr. Cir. 663 (1943), pp. 10, figs. 2*).—From a series of observations a table has been devised as an aid in determining the losses in yield of wheat due to different degrees of infestation by the spring generation of the hessian fly. Intermediate steps required investigations as to the relationship between the percentage of wheat culms infested and the number of purpuria per culm and also the approximate number of productive wheat culms to be found per acre. The results of experiments conducted under controlled conditions were included to substantiate and supplement the original observations. These showed that the hessian fly causes considerably more loss than that due solely to the lessened development of the grain, some of this loss including a stunting of the wheat culm to the point of nonproductivity.

**Factors predisposing animals to screwworm infestation in Texas.** H. E. PARISH. (*U. S. D. A.*). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 899-903).—Forty-three factors predisposing animals to screwworm infestation in eight classes of livestock were found in work conducted during the screwworm seasons of 1936, 1938, 1939, and part of 1940 in connection with a study of the larvicidal and protective action of various materials in Menard and Kimble Counties, Tex. The most frequently infested man-made wounds were shear cuts, which were responsible for 48 percent of the infestations in goats and 73 percent in kids. Of the eight types of wounds that may be eliminated, those from birth are by far the most important, making possible about 63 percent of the screwworm infestations in calves and 8 percent in cattle. Of the six types of wounds that may be eliminated in part, the most outstanding was that from needle grass, which was responsible for about 35 percent of the screwworm infestation in the lambs and about 27 percent in sheep. Four wound types that require the aid of research veterinarians are listed. Pink eye was the most important, it being responsible for about 18 percent of the screwworm attacks on lambs and about 6 percent on sheep. Eighteen types of wounds are listed that cannot be extensively controlled at the present time, but the screwworm flies that might infest these wounds can be reduced in numbers.

**Infestation of mature green papayas by the Mediterranean fruitfly.** C. B. KECK. (*U. S. D. A.*). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 802-805, figs. 2).—Records of the catch of Mediterranean fruitflies in a papaya grove in Hawaii trapped for a period of more than a year have shown that the population is never very high in a well-kept grove. A catch of 47 flies during a week in an avocado tree on the border of the papaya grove as compared with 15 flies in four traps for a month indicates that the papaya tree is not a suitable place for flies to congregate, possibly because of the lack of dense foliage. Of 23 samples of mature but unripe papayas picked from the trees, 6 were infested. It is suggested that papaya trees be planted at least 12 ft. apart so as to reduce the density of foliage where trees might overlap. It appears from observations made that keeping the grove free of ripening fruits prevents the fly population from building up and also forces flies drifting in to oviposit in the less mature fruits. The data indicate that the shipment of untreated mature green papayas to the mainland would result in the transportation also of the immature stages of the Mediterranean fruitfly.

**A laboratory method for evaluating feeding preference of fruitflies.** R. H. MARLOWE. (*U. S. D. A.*). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 799-802).—Description is given of a laboratory technic and a method of analyzing the data

statistically. Both the Mediterranean fruitfly and the melon fly prefer invert sugar sirup, white corn sirup, levulose, dextrose, and sucrose to a solution of Hawaiian cane molasses. The addition of acid lead arsenate or tartar emetic to the molasses spray did not affect feeding. The two insecticides were comparable in respect to feeding preference. Melon flies preferred a 5-percent cane molasses solution containing sucrose to the same spray without the sugar. An increase in the sucrose concentration from 1 to 12.5 lb. caused a corresponding increase in feeding preference. From 12.5 to 25 lb. there was very little increase in preference.

Studies on the toxicity of tartar emetic to the Mexican fruit fly (*Anastrepha ludens* Loew) and the effects of applications of tartar emetic on citrus trees, C. C. PLUMMER (*Ohio State Univ., Abs. Doctoral Diss., No. 35 (1941), pp. 117-122, fig. 1*).

Nectar and pollen plants of Oregon, H. A. SCULLEN and G. H. VANSSELL (Coop. U. S. D. A. et al.). (*Oregon Sta. Bul. 412 (1942), pp. 63, figs. 34*).—This publication contains a discussion of nectar and pollen and their sources, the floral areas of Oregon, plants that might injure bees, and methods for collecting and shipping honey plants for determination. Some 25 figures serve to illustrate some of the honey plants and their distribution in Oregon.

Susceptibility of honeybee larvae to individual inoculations with spores of *Bacillus* larvae, A. W. WOODROW. (U. S. D. A. coop. Ark., Iowa, Tex., Wis., and Wyo. Expt. Stas.). (*Jour. Econ. Ent., 35 (1942), No. 6, pp. 892-895*).—The author has found no evidence of larval resistance to American foulbrood although it is recognized that colonies through the behavior of adult bees do show distinct differences in resistance. A single spore apparently was sufficient to cause infection, although inoculations with large numbers of spores caused disease in a larger percentage of the larvae than did smaller numbers.

Effects of certain biological factors on the longevity of caged bees, L. M. BERTHOLF. (U. S. D. A. et al.). (*Jour. Econ. Ent., 35 (1942), No. 6, pp. 887-891, fig. 1*).—Observations of 23 lots of bees, each consisting of from 25 to 103 individuals taken from the flight board of a hive, age unknown, showed average longevities in captivity ranging from  $9.13 \pm 0.580$  days to  $22.90 \pm 1.065$  days, with a mean longevity of  $16.24 \pm 0.209$  days for the entire group. Bees taken in winter showed a small but statistically significant increase in longevity over those taken in summer, while the longevity of those taken in spring and autumn fell about halfway between. Tests on the longevity in captivity of 17 lots of bees of known age ranging from 0.5 to 80 days at the time of capture showed no clear-cut decrease in longevity until an age of more than 30 days was reached.

The life of Langstroth, F. NALLE (*Ithaca, N. Y.: Cornell Univ. Press, 1942, pp. 215, figs. [5]*).—This work of 12 chapters and an appendix is presented with a foreword and an introduction by E. F. Phillips.

Ants as predators of *Cochliomyia americana* C. & P., A. W. LINQUIST. (U. S. D. A.). (*Jour. Econ. Ent., 35 (1942), No. 6, pp. 850-852*).—Report is made of a study conducted at Uvalde, Tex., of the predators of the larvae and pupae of the screwworm during the warm seasons of the year. Ants were found to be valuable predators of third-stage larvae of this pest in the bodies of animals that die from screwworm infestations. They are abundant and come to a carcass before other blowfly larvae become numerous. An emergence of 4.1 percent of screwworm flies was recorded from exposed carcasses, but where the carcasses were protected 93.1-percent emergence resulted. In 196 field tests under a great variety of conditions, in which from 5 to 200 larvae were dropped so as to simulate the larvae escaping from wounds, a total emergence of 19.8 percent of flies was recorded. Larvae kept in jars and protected from ants yielded

from 70 to 100 percent emergence. It appears that larvae dropping in small numbers from wounds have a better chance of survival than when ensconced in a carcass, probably because it seems that carrion is an attractive medium to many species of ants. In both cases a low emergence is evident, and it is concluded that ants constitute an important natural control of the screwworm. This is in full effect from March to December and probably continues during the rest of the year.

**Abortive development in parasitic Hymenoptera induced by the food-plant of the insect host, S. E. FLANDERS.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 834-835).—Reference is made to recent investigations which indicate that marked physiological differences may exist between individuals of a single host species if such individuals feed on different food plants.

**A race of *Comperiella bifasciata* successfully parasitizes California red scale, H. S. SMITH.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 809-812).—The history of the introduction of the California red scale parasite *C. bifasciata* is briefly reviewed.

The experience with this parasite in California has emphasized the fact that (1) an accurate knowledge of the taxonomic relationships of the host insect is of great importance, even if it is necessary to resort to biological studies for their clarification, (2) recognition must be given to the possibility that the host plant may confer on the host insect a kind of immunity to parasitization, and (3) cognizance must be taken of the fact that there are host-limited races of insect parasites, and that, in any parasite-importation program, this must be given due consideration.

**Parasites of the filbert worm, S. M. DOHANIAN.** (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 6, pp. 836-841).—A discussion of parasites reared during the study of the filbert worm at Eugene, Oreg.

**A second introduced rat mite becomes annoying to man, H. E. EWING.** (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 9 (1942), No. 2, pp. 74-75).—An introduced mite *Allodermanyssus sanguineus* (Hirst), first recorded from the United States in 1923, although it had been collected in the District of Columbia in 1909, is now reported from Arizona, Georgia, New York, and Pennsylvania.

**A contribution to the biology of *Ornithodoros hermsi* Wheeler, Herms, and Meyer, C. M. WHEELER.** (Univ. Calif.). (*Jour. Parasitol.*, 29 (1943), No. 1, pp. 33-41, figs. 2).—A study of the biology of *O. hermsi* in which use was made of a constant temperature and humidity cabinet has shown the development from egg to egg to cover a period of 4 mo. and 16 days, requiring five instars from egg to adult with many of the larvae passing through two instars. The longevity of laboratory-reared ticks, with occasional feedings, was noted to cover a period of over 6.5 yr. from date of hatching to date of death. Infective adult ticks of unknown age taken in nature were observed to live in the laboratory for over 1.5 yr. Female ticks were able to withstand starvation for over 4 yr. This species occurs in the western United States, with records of capture from California, Idaho, and Colorado at elevations above 5,000 ft. and from Oregon at elevations of 3,000 and 3,600 ft. It is apparently a parasite of small mammals, particularly of species of western chipmunks belonging to the genus *Eutamias*.

## ANIMAL PRODUCTION

**Animal production in the post-war world, J. HAMMOND** (*Guernsey Breeders' Jour.*, 63 (1943), No. 1, pp. 22-23).—Needed efforts to increase production of dairy products, beef, mutton, lamb, and eggs after the war are reviewed.

**Our 1943 meat supply program, G. A. BROWN** (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 216-219).—Methods for increased production of meat animals based on better management practices and increased feeding are reviewed.

**[Animal production, poultry, and pasture investigations with livestock in the Southern States]** (*Assoc. South. Agr. Workers Proc.*, 43 (1942), pp. 90-94, 94-96, 97-100).—The following papers were presented at the annual meeting of the Association of Southern Agricultural Workers in continuation in part of investigations previously noted (E. S. R., 86, p. 224): Hybrid Beef Cattle, by A. O. Rhoad (pp. 90-91) (U. S. D. A.); Experiments in Spring Lamb Production, by C. M. Kincaid (p. 92) (Va. Expt. Sta.); Types of Ewes for Spring Lamb Production, by R. C. Miller (pp. 92-93) (Univ. Ky.); Pasture Improvement, by R. H. Lush (pp. 93-94); Forest Grazing With Beef Cattle, by J. E. Foster (pp. 94-95) (N. C. Sta.); Grazing Tests With Napier Grass, by W. G. Kirk, R. E. Blaser, and R. M. Crown (p. 96) (Univ. Fla.); Methods of Feeding Soybeans to Hogs, by E. H. Hostetler (pp. 97-98) (Univ. N. C.); Maintenance and Growth Requirements in the Rations of Fattening Steers, by A. L. Shealy (pp. 98-99) (Fla. Sta.); and General Report of the Committee on Policy of the Animal Husbandry Group, by J. B. Francioni, Jr. (pp. 99-100) (La. State Univ.).

**[Livestock and dairy investigations at the Arkansas Station]** (*Arkansas Sta. Bul.* 428 (1942), pp. 23-29, 47-49).—Brief results are presented of studies on the use for feeder calves of silage from Johnson grass, dough-stage and mature Atlas sorgo, and hegari; skim milk, whey, and pasture for pigs, and manganese, copper, and iron not needed under average conditions, both by S. R. Johnson; effects of nicotine sulfate and kamala on egg production, by R. M. Smith; counts of mold mycelia for quality in cream and butter, by T. J. Claydon; replacement of proteins by soybean products in poultry rations; and prospects and feeds for broiler production.

**[Investigations of livestock production at the Oklahoma Station]** (*Oklahoma Sta. Bien. Rpt.* 1941-42, pt. 1, pp. 26-33, 46-51, 51-53, 85-86, figs. 9).—Results are briefly presented on various grain concentrates and pasture for fat lamb production, molasses for fat lamb rations, ground Love grass hay for wethers, goats for clearing pastures, oats for fattening steers, urea in chick rations, feather picking prevented by fiber, breed variations in feed utilization by capons, laying tests for identifying production strains, satisfactory homemade electric brooders, and grazing and dry roughages for cattle.

**Studies on the chemical composition of pods and seeds of certain species of Medicago, with a note on the apparent digestibility of cluster clover (*Trifolium glomeratum* L.) seed, M. C. FRANKLIN and R. F. POWNING** (*Jour. Council Sci. and Indus. Res. [Austral.]*, 15 (1942), No. 3, pp. 191-200).—Study of seeds of different *Medicago* species showed that cluster clover seed was small and hard. Such seeds were held firmly within the hulls. Although there was considerable variability between species, the digestibility of the dry matter was increased 63 percent by grinding, and the digestibility of the crude protein was raised from 39.7 to 89.3 percent when fed with alfalfa chaff. Chemical analyses of samples of seeds from different species were presented.

**A comparison of acetic acid, fed in the form of triacetin, with glucose as a nutrient in feeds, T. B. McMANUS, C. B. BENDER, and J. F. GARRETT** (N. J. Expt. Stas.). (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 13-23, figs. 4).—A ration containing about 20 percent triacetin to supply acetic acid in the diet was palatable and had no harmful effect on rats. Rats which received 8.18 percent glycerol and 15 percent glucose in their diet made equal growth and showed equal efficiency in utilization of nutrients in 51 days. Growth of the rats was

not as good on a ration containing no glucose or triacetin, thus making the nutritive value of acetic acid evident. Heat production, respiratory quotients, and energy losses were ascertained with 3 lots of male and female rats comprising 48 animals.

**Vitamin A and carotene requirements of livestock, F. B. MORRISON.** (Cornell Univ.). (*Flour and Feed*, 43 (1943), No. 8, pp. 12-13).—A brief review of the vitamin A and carotene in yellow corn, hay, and silage, and the requirements of cattle, sheep, and swine for vitamin A.

**Carotene content of Texas range forages, A. R. KEMMERER, J. F. FUDGE, and G. S. FRAPS.** (Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 9, pp. 851-855).—Analysis of fresh, dried, and dormant grasses for the carotene content of different species showed the green forages to vary from 495 p. p. m. in Dallis grass to 2 p. p. m. in sotol bulb. Dried and dormant forages ranged from 2 p. p. m. in Bermuda grass to 94 p. p. m. in buffalo grass. Practically all of the dried and dormant range grasses would supply enough carotene for the maintenance requirements of 1,500  $\mu$ g. per 100 lb. live weight in beef cattle, discussed by Hart and Gullbert (E. S. R., 70, p. 662), but not enough to produce high milk production, studied by Fraps et al. (E. S. R., 72, p. 244). The  $\beta$ -carotene of the dried forage ranged from 61 to 94 percent of the crude carotene, but in sumac and kafir silage it ranged from 58 to 64 percent.

**Vitamin D content of shark liver oil, L. L. RUSOFF and N. R. MEHRHOF.** (Fla. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 47-48).—Florida shark-liver oil, previously found to be a potent source of vitamin A (E. S. R., 82, p. 378), contained about 35 A. O. A. C. chick units of vitamin D per gram. The experiment was carried out with 6 lots of 24 day-old crossbred (Rhode Island Red  $\delta$   $\times$  Light Sussex  $\eta$ ) chicks of both sexes. The bone ash averaged 31.09 percent for the controls and about 40 percent with 15 or 20 units of cod-liver oil or 0.50 percent of shark-liver oil. Pullets were consistently able to utilize vitamin D more efficiently than cockerels.

**Inspection of commercial feeding stuffs, H. R. KRAYBILL ET AL.** (*Indiana Sta. Cir.* 273 (1942), pp. 27, fig. 1).—The usual summary (E. S. R., 86, p. 664) of 3,931 samples of commercial feeding stuffs inspected in 1941, including the inspection of 63 samples of vitamin D supplements.

**Inspection of commercial feedstuffs, P. H. SMITH** (*Massachusetts Sta. Control Ser. Bul.* 113 (1942), pp. 25).—In the official inspection (E. S. R., 86, p. 817) of 1,518 samples of feeding stuffs in 1941, none sufficiently departed from guarantees to warrant prosecution. Data are included on the carotene content of alfalfa meals, manganese content of commercial mashes, the riboflavin of various products, protein quality of fish and meat meals, and the quality of ground oats found on Massachusetts markets.

**Beef calf production in Mississippi, R. H. MEANS, A. E. CULLISON, E. B. FERRIS, and S. P. CROCKETT** (*Mississippi Sta. Bul.* 371 (1942), pp. 25, figs. 7).—The results of pasture and breeding 340 native south Mississippi cows to registered Hereford and Aberdeen Angus bulls at State College, at the Natchez and Holly Spring Branch Stations, and in several land-use research areas, showed generally favorable results from the practices. Although the soil types of the pastures were decidedly different, the practices in producing and marketing the calves were generally satisfactory.

**The importance of body weight in selection of range ewes, C. E. TERRILL and J. A. STOEHR.** (U. S. D. A.). (*Jour. Anim. Sci.*, 1 (1942), No. 3, pp. 221-228).—The word "inversely" in line 8 of the abstract previously noted (E. S. R., 88, p. 233) should be deleted and the sentence followed by this addition: "There was an inverse relationship between average lifetime body weight and pounds

of lamb weaned per ewe year when considered independently of fall yearling weight."

**"Density" and some related characters of the fleece in the Australian Merino**, H. B. CARTER (*Jour. Council Sci. and Indus. Res. [Austral.]*, 15 (1942), No. 3, pp. 217-220).—Among South African and Australian Merinos there was found great variation in the density of the skin fiber population. Both the fleece yield and fleece quality enter into the density of the fibers. The examination of many samples of Australian Merino fleeces lends support to the suggestion that the Australian Merino is the product of cross-breeding in which there entered the Leicester, Lincoln, Cotswold, Romney Marsh, and, to a slight extent, the Southdown, with some unknown Asiatic breeds.

**Feeding methods and rations for fattening lambs**, P. S. JORDAN and W. H. PETERS (*Minnesota Sta. Bul.* 306, rev. (1942), pp. 16).—In continuation of previous investigations of feeding methods and rations for fattening lambs at Morris, Minn. (E. S. R., 71, p. 823), comparative results were reported for 30 lots of 30 lambs each hand-fed or self-fed on rations containing whole or ground corn or oats fed in different proportions with whole and cut alfalfa hay, with and without different percentages of linseed meal during fattening periods of 65-87 days' duration in 1938-42. Hand-feeding grains proved slightly more economical than self-feeding, but lambs could be successfully self-fed provided adequate hay was furnished. Cut alfalfa hay had no significant advantage over whole hay. While rate of gain was increased with linseed meal, there was no advantage in economy of gains. With mixtures of corn and cut alfalfa hay containing less than 40 percent hay, it was necessary to provide additional whole alfalfa hay. A mixture of 75 parts corn and 25 parts oats proved satisfactory for self-feeding with alfalfa hay. A summary is given of previous experiments with lambs conducted between 1926 and 1938.

**The value of various rations for fattening western lambs**, C. HARPER (*Indiana Sta. Bul.* 470 (1942), pp. 15).—In experiments with lambs the basic grain used in all experiments was shelled corn. There was employed corn silage with clover hay fed every day or on the fifth day only. Cut and whole soybean hay, alfalfa hay, or clover hay were employed for comparison in another experiment. The results given indicate that limestone and steamed bonemeal were of little value when added to rations containing legume hays, but with other rations there were advantages in feeding the minerals. Tankages consisting of meat meal and processed garbage were not as efficiently utilized as cottonseed meal. There was no advantage for chopping the legume hays or cracking the corn from the standpoint of increased gains and market finish, although feeding the cracked corn with cut hay eliminated some of the digestive difficulties in lambs consuming excesses of concentrates. The studies employed 8 lots of 25 lambs each for three comparisons from 1935 to 1937 and three more from 1937 to 1940. Data were recorded on the rates of gains and feed costs on the different rations.

**Sensory neuron degeneration in pigs.—IV, Protection afforded by calcium pantothenate and pyridoxine**, M. M. WINTROBE, M. H. MILLER, R. H. FOLLIS, JR., H. J. STEIN, C. MUSHATT, and S. HUMPHREYS (*Jour. Nutr.*, 24 (1942), No. 4, pp. 345-366, figs. 6).—Continuing these studies (E. S. R. 80, p. 382), abnormal gait and sensory neuron degeneration were observed in pigs failing to receive pyridoxine or calcium pantothenate, alone or in certain combinations with each other and with vitamins of the B complex and A. The basal diet consisting of casein, sugar, lard, a salt mixture, and cod-liver oil with the B vitamins promoted normal growth and no nervous symptoms. Whole liver was found to be an excellent source of both pantothenic acid and pyridoxine. Frac-

tions were shown to differ in their potency for protection from the sensory neuron degeneration. Since there were no signs of nutritional deficiency in pigs given no riboflavin, nicotinic acid, or vitamin A, it was assumed these substances were supplied in sufficient amounts in the basal ration. A subacute inflammation of the colon occurred in animals which did not receive calcium pantothenate. Animals not receiving pyridoxine exhibited epileptiform convulsions and anemia in addition to the abnormal gait. The full symptoms were not generally observed in the absence of one or more of the vitamins. In these experiments with 3-7 pigs on each ration, a total of 118 pigs were fed from 87 to 448 days of age. It was concluded that both pyridoxine and pantothenic acid were necessary to maintain the integrity of the nervous system.

**Confinement system of producing pork, E. L. HANSEN** (*Agr. Engin.*, 24 (1943), No. 1, pp. 9-10, figs. 2).—Losses due either to death or to poor development of animals diseased as a result of contact with infected soil can be greatly reduced by proper methods of sanitation. Many farmers are raising hogs on concrete in order both to control sanitation and to conserve feed. Some farrow their pigs on concrete, take them to pasture for awhile, then fatten them on concrete. Others keep their hogs on concrete from farrowing to market. Faster, cheaper gains are reported by hog farmers who make use of concrete. One farmer obtains the high average of 275 lb. per hog at 6 mo. of age with 300 lb. of feed for each 100 lb. of gain.

Expensive construction is unnecessary. Many farmers are making use of buildings and feeding floors already on the farm. Others need only a concrete feeding floor.

**Home pork production, J. SMEDLEY** (*New York: Orange Judd Pub. Co.*, 1942, pp. 134, figs. [27]).—A popular treatise on breeding, feeding, and management of swine and slaughtering and curing pork.

**Recent developments in the nutrition of horses, I. P. EARLE** (U. S. D. A.). (*North Amer. Vet.*, 23 (1942), No. 10, pp. 641-649).—The needs of horses for roughages and the vitamins are presented.

**Indiana stallion enrollment.**—Report of stallion enrollment board for the year 1941, with lists of stallions and jacks enrolled (*Indiana Sta. Cir.* 272 (1941), pp. 48, fig. 1).—The usual report (E. S. R., 85, p. 804) of stallions and jacks enrolled in Indiana, with discussions of the horse situation.

**The United States Morgan Horse Farm, R. W. PHILLIPS, D. A. SPENCER, S. R. SPEELMAN, W. H. BLACK, J. O. WILLIAMS, and I. P. EARLE** (*U. S. Dept. Agr., Bur. Anim. Indus.*, 1942, A. H. D. No. 52, pp. [1]+12, fig. 1).—Brief accounts are given of the experimental breeding, measures of performance, and fertility in horses, cross-breeding and reproduction studies with sheep, breeding investigations with dual-purpose cattle, and pasture studies at the Morgan Horse Farm at Weybridge, Vt.

**Essential factors in canine nutrition, W. C. RUSSELL** (N. J. Expt. Stas.). (*North Amer. Vet.*, 23 (1942), No. 11, pp. 733-736).—There are listed as essential for the dog five vitamins—A, thiamin, riboflavin, niacin, and B<sub>6</sub>.

**The poultry and egg situation outlook for 1943, C. G. CARD** (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 219-222).—Increased total poultry and egg production are suggested through improved breeding, feeding, and management practices.

**Studies on the amount of animal protein required in poultry rations, L. C. NORRIS and G. F. HEUSER** (Cornell Univ.) (*Flour and Feed*, 43 (1943), No. 8, p. 38).—In replicate experiments it was possible to compensate for a shortage of animal protein by increased amounts of soybean meal in the growth of chicks. Maximum growth was attained in cockerels to 8 weeks of age on

rations containing 3 percent fish meal with 60 percent protein and 25.5 percent soybean meal. A loss of weight occurred in the pullets on soybean meal alone, although as many eggs were produced and the hatchability was as good as when some animal protein was included. The loss in weight was prevented by additions of about 2 percent meat scrap with about 8 percent soybean meal in the ration.

**Effect of the war upon protein needs of poultry**, G. F. HEUSER and L. C. NORRIS (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, pp. 1, 3).—As little as 3 percent fish meal containing 60 percent protein promoted maximum growth in White Leghorn cockerels when the balance of the supplementary protein was obtained from 25.5 percent soybean meal. Although pullets laid normally and the eggs hatched well when soybean meal was given as the sole protein supplement, a loss of weight of the pullets occurred in a 30-week experiment. This loss was prevented when about 2 percent meat scrap was added to the ration.

**Soybean protein as a source of amino acids for the chick**, H. J. ALMQUIST, E. MECCHI, F. H. KRATZER, and C. R. GRAU. (Univ. Calif.). (*Jour. Nutr.*, 24 (1942), No. 4, pp. 385-392).—The principal growth-limiting deficiency of raw soybean protein was found to be methionine. At a 20 percent protein level supplied by raw soybeans, additions of 0.25 to 0.5 percent of methionine in the diet increased the percentage gain in weight of chicks per day from 2-3 percent to 6-7 percent, respectively. Heated soybean protein unsupplemented was able to support gains not far below the standard 7 percent level, but the rate of gain was slightly improved by further supplements of 0.13 percent methionine. No further benefits to the diet followed the inclusion of small amounts of choline, cystine, lysine, tryptophane, arginine, glycine, and gelatin as sources of other amino acids. These results were obtained with 29 lots of 8 chicks each fed from 1 week of age for 10-14 days on the raw and cooked soybean supplements with the different amino acids.

**Feed mixtures for broiler production**, H. D. POLK and C. E. BARNETT (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, pp. 4-6, figs. 2).—In three studies of the efficiency of protein sources for chick rations more economical gains were produced with proteins from animal and vegetable sources than from either alone. In rations with single sources of proteins which also included cottonseed meal, sun-dried shrimp meal, soybean meal, and meat scrap, machine-dried shrimp meal was the most satisfactory single high protein source in rations containing about 21 percent protein. This source of protein produced birds at 9 weeks of age that averaged only 0.65 oz. below those receiving a combination of cottonseed meal and machine-dried shrimp meal as the protein source which did the best of any of the groups. Cottonseed meal alone was the least satisfactory of the protein sources from the standpoint of average weight, slipped tendon, vigor, and condition. However, among 130 chicks fed meat scrap as the sole source of high protein in the three experiments there were 18 with slipped tendons and 10 rejects. The most economical gains were produced by a ration including protein from machine-dried shrimp meal, soybean meal, and cottonseed meal. Because of the high salt content, sun-dried shrimp meal was not as efficient as machine-dried shrimp meal. In the three experiments there were included 80-130 cockerels and 35-71 ♀s per lot.

**A method of measuring pulse rate of domestic fowl**, E. W. HENDERSON and H. E. HATHAWAY. (Mich. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 44-46, figs. 2).—Counts of the pulse rate of several breeds of fowls taken with an adapted amplified microphone-stethoscope and a dual speed recording machine indicated that the average pulse rate of fowls per minute was 370, with a standard deviation of  $\pm 30.86$ .

**Body form in growing chickens.—II, Growth of Cornish Bantams, R. G. JAAP, R. PENQUITE, and R. B. THOMPSON.** (Okla. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 11-19, figs. 4).—Continuing this series (E. S. R., 85, p. 658), the time required to produce averages of 2 lb. by ♂s and 1.5 lb. by ♀s was 8.5 and 7.5 weeks in White Wyandottes and 15 and 14 weeks, respectively, in Dark Cornish Bantams. Maximum shank length was attained at 15 weeks in ♀s of the Bantam and 16 weeks in White Wyandotte ♀s, while ♂s required 17 and 21 weeks, respectively. The shank length of Bantams was proportionally shorter than that of the Wyandottes. During the first 2-3 mo. the shanks in both breeds grew more rapidly than the body as a whole. Following the period of more rapid relative growth rate, the shank was depressed prior to its completion in size, making the relative growth of Bantams more like that of Wyandottes at the same age than at the same size. Similar ratios between the cube root of body weight and shank length remained the best single estimate of body form in chickens differing in size but similar in age. Shank body proportions at maturity appeared to determine their relative proportions at hatching but did not affect the relative changes which occurred with increasing age. The study was based on the growth and changes in proportions of the body weight and shank length of 75 Dark Cornish Bantams and 89 White Wyandottes at weekly intervals and by sexes during the first 20-24 weeks after hatching.

**The effect of diethylstilbestrol on the plasma phospholipids of the cock (*Gallus domesticus*), E. V. FLOCK and J. L. BOLLMAN** (*Jour. Biol. Chem.*, 144 (1942), No. 3, pp. 571-577, fig. 1).—When 1 mg. of diethylstilbestrol per kilogram live weight was administered to 15 mature cocks daily for 5 days, the phospholipids of the plasma increased continuously from a mean of 312 mg. to 1,952 mg. per 100 cc. of plasma 24 hr. after the last injection. They returned to normal within a few days, however. The ratio of choline phospholipids to cephalins was not greatly altered during intense production, since both participated in the normal increase occurring during the recovery period. There was a more rapid decrease in the cephalin fraction.

**Effect of *Lactobacillus casei* ε eluate fraction on reproduction in the domestic fowl, W. W. CRAVENS, E. E. SEBESTA, J. G. HALPIN, and E. B. HART.** (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 106-108, fig. 1).—Continuing these investigations (E. S. R., 86, p. 667), the results of two experiments, although with small numbers of pullets, showed that both solubilized liver extract and a norite eluate of solubilized liver extract contained a factor or factors essential for normal development of the chicken embryo. Deficiency of the eluate fraction caused a more pronounced effect on hatchability than on egg production. With a norite supplement to the basal ration, a pullet came into egg production in 3 weeks and then stopped laying until 4 weeks after 0.2 percent inositol was added. Laying continued with inositol alone, but the eggs failed to hatch until the norite eluate was added.

**Egg-production behavior of hens, W. C. THOMPSON** (*New Jersey Stat. Bul.* 700 (1942), pp. 12, figs. 3).—The annual egg production of Single-Comb White Leghorn and Rhode Island Red hens in the Vineland egg laying contest in the first and succeeding years showed that capacity to continue egg production at reasonably high levels was a characteristic possessed by many fowls in both breeds. Variation existed for egg yield in succeeding years which was not related to the first year's egg production. Minimum standards of 225, 170, 150, and 130 eggs were chosen for the first, second, third, and fourth years' production, respectively, in Single-Comb White Leghorns. Frequent checking of non-trapnested flocks with the percentage of hen days on which eggs were produced is suggested for maintaining laying flocks at high production levels.

**Gastric hydrogen ion concentration and acidity in the domestic fowl**, D. S. FARNER. (Univ. Wis.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 79-82, fig. 1).—In connection with studies of the pH of the digestive tract of fowls (E. S. R., 88, p. 236), the mean pH of the gastric juice in the gizzards of hens on a ration of equal parts of corn, wheat, and oats was 2.05. Some diurnal variation existed, showing a tendency for the pH to be lower in the daytime and higher at night. The gizzard fluid was removed from 30 Rhode Island Red and Barred Plymouth Rock hens with trochar and syringe at various times of day and night.

**Acorns of the willow oak, *Quercus phellos*, a source of vitamin A activity**, T. R. KING and H. W. TITUS. (Va. A. and M. Col. and U. S. D. A.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 56-60).—In feeding experiments with growing Rhode Island Red chicks the inclusion of 1 percent of ground acorn kernels and shells of the willow oak in a deficient vitamin A diet was as effective in maintaining growth and viability as 108  $\mu$ g. of carotene in peanut oil per 100 gm. of feed. Growth was retarded by the inclusion in the diet of 40 percent of acorns but 20 percent and smaller amounts did not produce unfavorable effects. It was calculated that the willow oak acorns contained 180 I. U. of vitamin A per gram. The flesh of all chicks that received 2 percent or more of acorns in the diet was yellow in color, its intensity increasing with the percentage of acorns consumed. The studies were conducted in three experiments with 4 lots of 15-30 chicks each, fed from 45 to 60 days on rations containing 0, 0.5, 1, 2, 2.5, 5, 10, 20, and 40 percent acorns as supplements to a ration deficient in vitamin A (E. S. R., 77, p. 527).

**The absorption and retention of carotene and vitamin A by hens on normal and low fat rations**, W. C. RUSSELL, M. W. TAYLOR, H. A. WALKER, and L. J. POLSKIN. (N. J. Expt. Stas.). (*Jour. Nutr.*, 24 (1942), No. 3, pp. 199-211, fig. 1).—Continuing studies of the role of fat in poultry nutrition (E. S. R., 83, p. 672), the absorption by hens of carotene in the crystalline form was about 60 percent of the consumption on a normal ration containing 3.83 percent fat for about 70 days, as contrasted with about 20 percent absorption of similar amounts of carotene consumed by hens on a ration with the fat extracted to 0.07 percent. On normal rations hens showed an increasing tendency to absorb carotene as increased amounts were supplied, but the increased absorption was not shown on the low fat ration. Absorption of vitamin A was essentially the same with normal and low fat rations, and the percentage of absorption was not changed by increased amounts of vitamin A in the ration. A yellow pigment having the solubility properties of carotene, but according to spectrophotometric determination not carotene, appeared in the excreta of hens on the low fat rations. The amount served for correction of the yellow material on normal rations. There was a much greater retention of vitamin A in the liver when a normal ration was fed than on a low fat ration, as ascertained by liver assays 30 days after the cessation of vitamin A feeding. When amounts of carotene comparable to that in the feed were administered intravenously none was excreted with the low fat ration. In the conduct of the study, hens on normal and low fat rations were supplied with different amounts of crystalline carotene and vitamin A in the ration or intravenously with determinations of the amounts in the excreta. The hens were first depleted for 10 weeks without carotene, and then carried up to 79 days with supplements and finally for 1 mo. without vitamin A for liver analysis.

**Ascorbic acid storage in vitamin A deficient hens**, M. RUBIN and H. R. BIRD. (Md. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 53-55).—The ascorbic acid content of the livers and duodena of 16 hens on deficient vitamin A rations for

at least 11 weeks was as high as or higher than that from hens which received additional vitamin A or normal rations. It thus appeared that vitamin A deficiency did not interfere with ascorbic acid synthesis in the mature chicken as in cattle, as noted by Phillips (E. S. R., 84, p. 508).

**Use of pure riboflavin in poultry mashes and concentrates,** D. R. CLANDININ, C. W. TRAVES, and W. HENDERSON (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 12, pp. 650-651, 661).—No statistical difference was found in the fertility and hatchability of eggs from hens on an all mash ration including 7 percent buttermilk powder, and others which received no buttermilk powder in the mash but were given the amount of riboflavin estimated to be present and further protein at 1, 2, and 4 percent as fish meal, meat meal, and grain, respectively. The studies were conducted with 6 lots of 10 hens each.

**Effect of vitamin B<sub>6</sub> on egg production and hatchability,** W. W. CRAVENS, E. E. SEBESTA, J. G. HALPIN, and E. B. HAET. (Wis. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 94-95).—The need of vitamin B<sub>6</sub> for normal reproduction by laying hens was demonstrated. Groups of three hens each received supplements of 0, 1, 2, 3, and 4 mg. B<sub>6</sub> per kilogram of ration over a 9-week period. Egg production, fertility, and hatchability decreased to practically 0 on the basal ration, but hatchability was nearly 100 percent with the supplement of 4 mg. of B<sub>6</sub> per kilogram of ration.

**Dietary calcium and phosphorus levels and the vitamin D requirement of the chick,** J. S. NOWOTARSKI and H. R. BIRD. (Md. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 72-78).—In two experiments the percentage of bone ash in chicks at 3 weeks of age was increased more by the addition of minerals to the basal mash than by the addition of 20 A. O. A. C. units of vitamin D per 100 gm. of the basal ration, and the bone ash was well within the normal range. Between 3 and 10 weeks the bone ash of chicks on high mineral rations without vitamin D decreased. High mineral levels were less effective than vitamin D supplements in promoting growth and preventing crooked breastbones. Optimum growth and bone ash were obtained without vitamin D with rations having calcium contents up to 4.42 percent to 3 weeks of age. When 5 units of vitamin D were added to a ration containing 3.6 percent calcium and 1.8 percent phosphorus, better growth, feed efficiency, and bone ash were induced to 10 weeks of age than with 10 units of vitamin D and a ration containing 1.7 percent calcium and 0.85 percent phosphorus. Growth, feed efficiency, and feathering were improved, and mortality, crooked breastbones, and perosis reduced by the addition of 0.1 percent choline to mineralized rations. The studies were conducted in two experiments with 10 groups of 36 White Leghorn cockerels in the first and 13 groups of 40 Barred Plymouth Rock × New Hampshire cross-bred chicks in the second. In each case part of the chicks were slaughtered at 3 weeks of age for bone ash determinations. Various supplements, which included deflorinated phosphate, ground oyster shell, K<sub>2</sub>HPO<sub>4</sub>, MnSO<sub>4</sub>, 4H<sub>2</sub>O, choline, and vitamin D, were employed. Records were kept of the weights, mortality, and bone ash at 3 and 10 weeks of age.

**Edema in vitamin E deficient chicks,** H. R. BIRD. (Md. Expt. Sta.). (*Science*, 97 (1943), No. 2508, p. 98).—Confirming the results of Dam and Glavind<sup>1</sup> that increasing concentrations of soluble salts in the ration caused an increased severity of edema in chicks on low vitamin E rations, it appeared that disturbances of the osmotic equilibrium were necessary in addition to vitamin E deficiency to cause generalized edema, since it was not produced on E-deficient rations until a NaCl solution was administered. The vitamin E content

<sup>1</sup> Science, 96 (1942), No. 2488, pp. 235-236.

of poultry mashes was estimated from their edema protective value. The relation of edema to hemorrhage in encephalomalacia, as pointed out by Pappenheimer et al. (E. S. R., 81, p. 696), is noted.

**The origin and structure of the vitelline membrane of the domestic fowl's egg, E. H. McNALLY.** (U. S. D. A.) (*Poultry Sci.*, 22 (1943), No. 1, pp. 40-43, figs. 2).—Histological sections of the ovary, larger follicle walls, and the vitelline membranes from the yolks of hens' eggs that had been laid showed the true vitelline membrane on the freshly ovulated yolk to be formed from the collagenous membrane of the follicle, which becomes swollen by contact with the oviduct secretions. The later thickening and toughening of the collagenous membrane protects the yolk against rupture.

**Some characteristics of the ovomucin gel of egg white, E. H. McNALLY.** (U. S. D. A.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 25-29, figs. 2).—Titration curves of thick and thin egg white from fresh and incubated eggs showed that ovomucin white was practically insoluble in distilled water. It gave reversible physical changes due to pH and salt concentrations, and was in a compact precipitated form when the pH was less than 6-6.4. Between pH 6 to about 8.5 the ovomucin swells to a gel and on increased alkalinity becomes a viscous mucus. The amount of acid neutralizing the material in the white of fresh and incubated eggs was similar.

**Shell treatment of eggs by oiling.—I, Effect of time between production and oiling on interior quality of stored eggs, R. J. EVANS and J. S. CARVER.** (Wash. Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 10, pp. 546-549).—The interior quality of storage eggs was best preserved and the air cell size held to a minimum by oiling on the day the eggs were laid. When longer periods of time elapsed between laying and oiling, or the eggs were not oiled at all, there were greater decreases in the albumen index during short storage periods at higher temperatures or longer storage periods at 26°-34° F. The greatest decrease of firm albumen occurred in unoiled eggs. The studies were conducted in three experiments with groups of 12-24 eggs with four and eight replications of oiling the eggs when gathered, at noon and the evening of the day gathered. Comparisons were also made of oiling on the first, third, and seventh day thereafter, or not oiling at all, with storage at different temperatures.

**Does boiling change the weight of an egg or of the yolk or white? G. D. BUCKNER, W. M. INSKO, Jr., and A. HARMS.** (Ky. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, p. 95).—The weights of whites, yolks, and shells of eggs from 10 Rhode Island Red pullets and hens when fresh and after boiling for 30 min. did not differ significantly. The greater weight of the hens' eggs than pullets' resulted mainly from an increase in the egg white.

**Preservation of eggs, II-IV (Canad. Jour. Res., 20 (1942), No. 10, Sect. D, pp. 291-319, fig. 1).**—Three papers in this series<sup>2</sup> are reported.

**II. Surface contamination on egg-shell in relation to spoilage, F. T. Rosser** (pp. 291-296).—No very close relationship was found between the external mold growth after storage for 6 weeks under adverse conditions of both temperature and humidity and the amount of mold contamination originally present on the shell. Internal spoilage as determined by candling was greatest at the end of the storage period for eggs having high initial shell counts. The spoilage was not reduced by dipping in oil before or after disinfecting the eggs in hydrogen peroxide.

**III. Studies on the effect of oil treatment and egg-case liner bags in the preservation of shell eggs under adverse conditions, E. J. Reedman and J. W. Hopkins** (pp. 297-305).—Oil treatment of eggs and packing in sealed egg-case liner bags

<sup>2</sup> Canad. Jour. Res., 20 (1942), No. 3, Sect. D., pp. 57-70, fig. 1.

retarded the development of internal defects and severe external molds at 32° and 70° F. and about 90 percent humidity. The use of egg-case liner bags on untreated eggs in storage was detrimental. The position of eggs in the case influenced spoilage during the storage period. The importance of humidity was emphasized.

IV. *Storage of oiled and bagged eggs under constant and alternating temperatures and humidities*, N. E. Gibbons, C. O. Fulton, and J. W. Hopkins (pp. 306-319).—Within rather wide limits microbiological development in stored and oiled eggs was dependent primarily upon storage conditions rather than the amount of inoculum on the surface of the egg shells. Oiled and unoled eggs were stored at different temperatures and humidity, ranging from 60° F and 90 percent relative humidity to 80° and 95 percent relative humidity for 6 weeks. Three levels of shell contamination were introduced by dipping the eggs in saline suspensions of molds and bacteria. Oiling and bagging reduced internal mold and rot, and they were in better condition after storage than untreated eggs. The air cells were smaller, yolks freer, and less distinct yolk shadows were produced.

**Storage changes in spray-dried whole egg powder**, L. S. STUART, H. H. HALL, and E. E. DICKS. (U. S. D. A.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 12, pp. 629-633, 658, figs. 2).—Preliminary bacteriological and chemical analyses on spray-dried whole egg powder incubated at 30° C. for 60 days at 13 relative humidities from 20 to 100 percent showed that the most important factor in the preservation of good quality during storage was the control of the moisture content of the product. Practically no bacterial and little mold growth occurred in samples stored at 90 percent relative humidity or less. Such samples contained less than 10 percent moisture concentrations. Chemical changes were noted in egg powder stored at the higher humidities which were associated with microbial activity. The recommendation for practice is the production of egg powder containing 5 percent or less moisture and adequate care in the handling to prevent moisture absorption. In the bacteriological studies determinations were made of the total bacterial counts, lipolytic organisms, molds present, and the coli index. The chemical determinations included the free fatty acids and total crude and free carboxyl groups before and after storage.

**The management of turkey breeders**, I, II, G. C. CRANDALL (*New Jersey Stas. Hints to Poultrymen*, 29 (1942), No. 6, pp. 4; 30 (1942), No. 1, pp. 4, figs. 2).—The general discussion of turkey production (E. S. R., 85, p. 808) is continued in two parts. In part 1 directions are given for caring for breeders, fertility and hatchability, use of artificial lights to stimulate egg production, and the yards and equipment needed for turkeys. Part 2 gives general directions for equipment and feeding, including two suggested breeder rations.

**The relative efficiency of gains in weight made by male and female Bronze turkeys**, E. M. FUNK. (Mo. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 3-10, figs. 4).—Differences between the economy of gains made by ♂ and ♀ Bronze turkeys were highly significant after 16 weeks of age. The ♂ turkeys required less protein per pound of gain from 17 to 30 weeks, utilized carbonaceous material more efficiently, and produced gains at smaller unit costs than ♀s. Males grew more rapidly than ♀s, and the rate of gain was related to the efficiency of feed utilization. Males required less feed per pound of gain, but the ♀s consumed a greater proportion of the less expensive feeds (grain). The study was based on weekly feed consumption and weights of 4 lots of about 25 birds of both sexes raised in complete confinement to 24 weeks of age in 1940, and 4 lots of 8-14 ♂s and ♀s raised in confinement to 30 weeks of age on rations of yellow corn and oats with access to mash of 27, 32, 36, and 40 percent protein.

**Perosis in turkey poults and the choline content of their diets**, R. J. EVANS, M. RHIAN, and C. I. DRAPER. (Wash. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 88-93).—On several rations for poults the highest incidence of perosis with a perosis score of 5.71 (E. S. R., 88, p. 237) was produced on a high protein diet containing 25.6 percent pea meal and 22 percent casein. The occurrence of perosis was almost entirely eliminated by choline additions of 0.14 percent. There was a high negative correlation of  $-0.785$  between the incidence of perosis and the choline content of the ration. Additions of 0.05 percent choline in the casein-protein diet caused a marked decrease in the incidence of perosis, but further additions of choline did not cause a reduction in the amount of perosis. Likewise, in another experiment with casein and extracted fish meal, supplements of choline to 0.15 percent reduced perosis, but above this level perosis was increased. Blood and bone phosphatase values showed no relation of the degree of perosis observed or the choline content of the ration. These studies were conducted in three experiments with groups of 15 day-old poults fed for 4 weeks on a perosis-producing basal ration, or with rations in which the protein was supplied from casein, meat scrap, extracted and unextracted fish meal, soybean meal, and pea meal, with and without choline supplements.

### DAIRY FARMING—DAIRYING

[Papers on dairy production and the manufacture of dairy products by the southern experiment stations] (*Assoc. South. Agr. Workers Proc.*, 43 (1942), pp. 101-109, 111-125).—The results of reports on the following subjects were presented before the annual meeting in Memphis, Tenn., February 4-6, 1942 (E. S. R., 86, p. 373): A Method of Presenting Herd Analyses, by D. M. Seath and R. Lowe (p. 101) (La. Expt. Sta.); The Repeatability of Various Portions of the Lactation of Dairy Cows and Their Relative Value as Indicators of Permanent Productivity, by W. Gifford (pp. 101-102) (Univ. Ark.); The Influence of Rising Feed Prices Upon Our Milk Production Program, by K. M. Antrey (pp. 102-103) (Univ. Ga.); Sweet Potato Meal as a Milk-Producing Ration for Dairy Cattle, by Z. A. Massey (pp. 103-104) (Ga. Sta.); Irrigated Pasture for Dairy Cows, by C. E. Wylie, L. R. Neel, and J. A. Schaller (pp. 104-105) (Univ. Tenn. et al.); Seasonal Variation of the Vitamin A Content of Milk as Related to Pasture and Feeding Practices, by C. J. Koehn (pp. 105-106) (Ala. Sta.); Shark Liver Oil and the Vitamin A Potency of Milk, by L. L. Rusoff, H. E. Skipper, and P. T. D. Arnold (pp. 106-107) (Fla. Sta.); Vitamin "A" Requirements of Dairy Cattle, by A. H. Kuhlman (pp. 107-108) (Okla. A. and M. Col.); Lipolytic Activity of Bovine Mammary Gland Tissue, by P. L. Kelly (pp. 108-109) (Univ. Ark.); The Effect of Type of Cooler and Holding Time on Quality of Milk, by A. J. Gelpi et al. (pp. 111-112) (La. State Univ.); Bitterweed Studies, by F. H. Herzer (pp. 112-113) (Miss. State Col.); The Making of Cottage Cheese From Reconstituted Skim-milk Powder and the Quick Freezing and Storage of Cottage Cheese, by T. B. Harrison and W. Roberts (pp. 113-114) (Univ. Tenn.); A New Method for Manufacturing American Cheddar Cheese, by W. D. Saunders (p. 114) (Va. Sta.); Some of the Factors Affecting the Curing of Cheddar Cheese, by F. E. Hanson (pp. 114-115) (Tex. Sta.); Cheese Making Problems in the South, by L. K. Riggs (p. 115); Quality as Related to the Consumption of Dairy Products, by H. B. Henderson (pp. 115-116) (Univ. Ga.); Preliminary Report on the Storage of Frozen Cream, by T. R. Freeman and L. E. Mull (pp. 116-117) (Fla. Sta.); A Study of Cream Grading at Franklin, Kentucky, by H. B. Morrison and J. O. Barkman (pp. 117-118) (Univ. Ky.); Some Factors Affecting the Mold Content of Cream and the Mycella Count of Butter, by T. J. Claydon (pp. 118-

119) (Univ. Ark.); Some Observations on Mold Mycelia in Cream and Butter, by S. C. Trzcinski and H. C. Olson (p. 119) (Okla. A. and M. Col.); Free Fatty Acids in Cream and Their Effects on Butter Quality, by E. L. Fouts (pp. 119-120) (Fla. Sta.); The Resistance of Fatty Acids to Neutralization, by P. E. Johnson and E. L. Fouts (pp. 120-121), and Comparative Value of Various Methods for Determining the Keeping Quality of Butter, by W. A. Krienke and E. L. Fouts (p. 121) (both Okla. A. and M. Col.); Some Observations on the Treatment of Parchment Wrappers With Sodium and Calcium Propionates for the Inhibition of Mold Growth on the Surface of Butter, by J. C. Olson and H. Macy (p. 122) (Univ. Minn.); The Effect of Feeding Cottonseed Meal as the Sole Concentrate on the Chemical and Physical Properties of Milk, by P. G. Miller (pp. 122-123) (S. C. Sta.); A Student Chapter of the American Dairy Science Association, by P. M. Reaves (p. 123) (Va. A. and M. Col.); Research in Dairy-ling, by E. C. Elting (pp. 123-124) (U. S. D. A.); and Adequate and Economic Housing of the Entire Dairy Herd, by L. A. Higgins (pp. 124-125) (Miss. State Col.).

[Results of experiments on dairy cattle and dairy products at the Oklahoma Station] (*Oklahoma Sta. Bion. Rpt. 1941-42, pt. 1, pp. 34-37, figs. 2*).—Results are briefly reported on the use of prairie hay for dairy cattle, prairie hay as a source of vitamin A, cottonseed meal in place of corn for milk production, rancidity in individual cow's milk, and mold studies in cream and butter.

**Growth studies with Ayrshire cattle.—I, Normal body weights and heights at shoulders for Ayrshire cattle,** G. A. BOWLING and D. N. PUTNAM. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 47-52, figs. 2).—The birth weights, monthly body weights, and monthly height-at-shoulders for 242 Ayrshire females born at the Reymann Memorial farm from January 1927 to 1942 and for 165 Ayrshire males born during the same interval are presented and compared with similar data collected at the Missouri (E. S. R., 43, p. 876) and Iowa (E. S. R., 69, p. 100) Experiment Stations.

**The oscillatory character of the variations in the weights of dairy heifers,** G. A. BAKER and S. W. MEAD. (Univ. Calif.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 967-974, figs. 2).—The daily increases in weights of Holstein heifers receiving a nonroughage ration from 100 days of age were shown to be regular for about 193 days, but at the age of 293 days on April 1 the rate of daily gain increased and the variability of the daily weights markedly increased. Variance from the straight line regression in the first period calculated at 160.21 was significantly less than the variance of 233.09 for the second period. More of the variance was due to oscillatory variation in the first than in the second period. The variations in the weights of the older heifers were similar to those for yearling beef heifers on a normal alfalfa hay ration (E. S. R., 88, p. 515), indicating that the different behavior was a matter of age and not diet. Misleading conclusions could be derived from feeding trials based on weights at certain parts of the natural oscillations. It is, therefore, recommended that for short-time trials several animals be included with uniform environment and frequent weighings. The study was based on three consecutive weights at 10-day intervals on nine heifers from September 13 to March 24 and seven of them to August 21 with nonroughage rations.

**Overcoming some of the dairy problems,** E. WEAVER (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 211-215).—General suggestions for increasing total milk production to meet wartime goals and needs.

**Balance the ration for most efficient milk production,** G. WERNER and G. BOHSTEDT. (Univ. Wis.). (*Guernsey Breeders' Jour.*, 62 (1942), No. 12, pp. 1063-1065).—Practical directions for feeding efficiently with and without pasture and for balancing the rations for dairy cattle.

**Efficiency of dairy rations containing various quantities of grain, K. M. AUBREY, C. Y. CANNON, and D. L. ESPE** (*Iowa Sta. Res. Bul. 305 (1942), pp. 105-139, figs. 3*).—In two series of experiments comparing three planes of nutrition for dairy cattle, roughage alone and limited grain rations supplied insufficient nutrients to meet the requirements of cattle consuming them, judging by weight losses. The loss was not the case with full-fed cattle. Statistical analysis of the relation of fat-corrected milk to digestible nutrients consumed showed highly significant differences in favor of the roughage-alone rations. The efficiency of the roughage rations decreased as the stage of lactation advanced. When calculated without regard to live weight changes, the average pounds of milk produced for each pound of digestible nutrients consumed above maintenance were 5.76 on roughage alone, 4.09 for the limited grain ration, and 3.2 lb. on the full grain ration. The first experiment was conducted with 15 cows divided into 3 groups, 2 of which were fed by the double reversal method for 7 weeks on roughage alone or rations containing 1 lb. of grain to 8 lb. of milk produced. The control group was fed throughout the three periods on rations of 1 lb. of grain for each 4 lb. of milk. The second experiment was conducted with 18 cows divided into 6 outcome groups by the method devised for variance analysis (E. S. R., 86, p. 668) and fed in periods of 6 weeks each. The rations compared were all roughage and 1 lb. of grain to 7 and 3.5 lb. of milk produced. In both experiments the cattle were allowed all the alfalfa hay and silage they would consume with daily records of milk and fat produced.

**The effect of shark liver oil on milk and butter fat production, C. JENSEN, P. D. BOYER, P. H. PHILLIPS, I. W. RUPEL, and N. S. LUNDQUIST.** (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 931-937, fig. 1).—In three experiments with dairy cattle on adequate rations, feeding of high vitamin A potency shark-liver oil containing 15,400 or 26,650 units brought about a distinct rise in the blood plasma vitamin A, but there was a marked decline in the blood plasma and the milk carotene when vitamin A supplements were fed. The production of milk and butterfat and the percentage of butterfat were not influenced by the high vitamin A shark-liver oil feeding. Feeding as much as 90 cc. of the shark-liver oil per day tended to increase the normal rate of decline in production with advancing lactation.

**Producing milk rich in vitamin A, J. H. HILTON, J. W. WILBUR, and S. M. HAUGE.** (*Indiana Sta. Cir. 274 (1942), pp. 8, figs. 4*).—Methods of feeding dairy cattle to insure high vitamin A values in the milk are described.

**The effect of oxytocin on milk and milk fat secretion, J. C. SHAW.** ([Conn.] Storrs Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 12, pp. 1051-1055, figs. 2).—The decrease in milk and fat secretion of four cows following oxytocin injections averaging 1.6 and 13.8 percent, respectively, was thought to be due to the more complete discharge of the mammary gland. Milking at 2-hr. intervals with the aid of oxytocin decreased milk fat secretion 11 percent in 24 hr. by inhibiting passage of blood fat into the glandular tissue. The secretion of milk seemed relatively constant and not influenced by removal of the milk at different intervals.

**The addition of carotenoids as a means of maintaining a uniform color in milk as measured by the Lac-chrom-meter, E. B. WILLIAMS, L. H. BURWALD, and R. G. WASHBURN.** (Ohio Expt Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 12, pp. 1003-1014, fig. 1).—Readings by the Munsell "Lac-chrom-meter" as described by Baumann and Steenbock (E. S. R., 71, p. 94) of milk standardized to 5 percent butterfat showed the Guernsey milk to be consistently higher, followed in order by Jersey, Ayrshire, Brown Swiss, and Holstein. The color was generally lower until the cows were turned on green pasture, when there was

a greater increase in the color of Guernsey milk than in the milk of the other breeds. The peak of color was reached in 3 weeks with a decline until August, yet the carotene content of the milk actually increased. The color content of the milk was increased approximately one unit for each addition of 300  $\mu\text{g}$ . of carotene per quart of milk. Additions of 450  $\mu\text{g}$ . of carotene per quart were needed to make the color of winter milk equivalent to the maximum color of summer milk. The micrograms of carotene per quart of 5 percent milk needed to match Guernsey milk were 600 for Ayrshires, Holsteins, and Brown Swiss, and 450 for mixed herd milk, with 300 sufficient for the same milk after homogenization. The Lac-chrom-meter reading increased as the size of the fat globules was decreased by homogenization. Visual color did not increase in proportion to the Lac-chrom-meter readings. It was noted that these readings increased more as a result of homogenization than visual color, but when carotene was added the increase in visual color was proportionally greater than increases in the Lac-chrom-meter readings.

**Normal variations in the amount of ascorbic acid in the blood of dairy cattle,** A. L. BORTREE, C. F. HUFFMAN, and C. W. DUNCAN. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 983-990).—The average ascorbic acid content of the blood of 19 calves from birth to 12 mo. was 0.32 mg. per 100 cc. of plasma, of 4 heifers from 20 to 34 mo. of age 0.49 mg., and of 24 cows of various ages 0.44 mg. Marked differences in the ascorbic acid of the blood plasma of normal calves and lactating cows were found, but the fluctuations were not correlated with the periods of feeding or the time when the samples were taken. Random ascorbic acid determinations seemed of little value in indicating the blood concentration of this vitamin in dairy animals.

**The heritability of butterfat production in dairy cattle,** J. L. LUSH and F. S. STRAUS. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 975-982).—In continuing further studies of sire indexes (E. S. R., 86, p. 234), the heritability of differences between cows mated to the same sire was found to be 0.174. This indicates that two cows chosen on the basis of one record each will differ in their breeding values about one-sixth as much as their records differ. In selecting cows for high records their breeding values are about one-sixth above the average of the group from which they were chosen. The contributions of like environment caused a reduction from 0.174 to 0.140 for the heritability within a single herd. Breed differences were not found in heritability of differences. The 305-day records of 2,154 daughter-dam comparisons used in proving 283 sires in the Iowa Dairy Herd Improvement Associations served as the basis for the study. The numbers of daughters' records per sire ranged from 5 to more than 20.

**Predicting 305-day yields from short-time records,** C. Y. CANNON, J. B. FRYE, JR., and J. A. SIMS. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 12, pp. 991-999, figs. 2).—Full lactation records could be predicted from a single month's record or from a single day's record each month. Factors are presented for predicting the 10 months' butterfat production from any month's record or a test day's production in any of the months. The data are based on linear regression equations for the butterfat production records of 400 Holstein-Friesian cows in the station herd and 1,289 cows, mostly of the Holstein, Guernsey, and Jersey breeds in the Iowa Dairy Herd Improvement Associations. The different breeds showed similar lactation curves. The persistency index of the station cows was 92.3 and for the Dairy Herd Improvement Association cows 91. The standard error of estimate showed the fifth month to give the most accurate indication of the full lactation yield. The sixth, seventh, and fourth months' records proved next best in that order.

**An artificial insemination schedule**, J. P. LAMASTER (*Guernsey Breeders' Jour.*, 63 (1943), No. 3, p. 173).—The records of artificial insemination in the Clemson, S. C., dairy herd served as the basis for a schedule based on insemination late in oestrus with semen stored for 24 hr. or less.

**War emergency plans for raising calves and heifers**, E. S. SAVAGE, W. E. KBAUSS, and S. W. MEAD (*Holstein-Friesian World*, 39 (1942), No. 25, pp. 9-10, 36-37, 46).—The needs of calves and heifers up to calving are reviewed with recommendations of dry feed systems needed to produce satisfactory development with a minimum of whole milk and skim milk which may be diverted for emergency purposes.

**The A B C of goat dairying**, F. R. COUTANT (*Fairbury, Nebr.: Dairy Goat Jour.*, 1941, pp. 116, [figs. 58]).—General directions for milk goat production.

**A cheap and efficient medium for the plate count of milk**, H. BARKWORTH and J. G. DAVIS (*Jour. Hyg. [London]*, 42 (1942), No. 2, pp. 218-223).—In order to reduce the amount of peptone needed, comparisons of 20 different formulas for media to serve for bacteriological plate counts of milk were made. These were based on milk samples from 274 farms which showed that ease of counting could not be obtained with less than 0.2 percent peptone in the media. There were included in the samples employed varying percentages of peptone, yeastrel, lab-lemco, agar fiber, and dextrose.

**Thermophilic and thermoduric bacteria**, W. B. SARLES. (Univ. Wis.). (*Dairy Indus.*, 7 (1942), No. 11, pp. 279-280, 288).—Methods for the identification and freeing of milk of heat-resistant (thermoduric) and heat-loving (thermophilic) bacteria are presented.

**A comparison of various methods for detecting thermoduric bacteria in milk**, J. B. FISCHER and C. K. JOHNS (*Jour. Milk Technol.*, 5 (1942), No. 5, pp. 269-275, figs. 5).—The tube technic of Myers and Pence (*E. S. R.*, 85, p. 661) in comparative counts of 132 pasteurized milk samples from three plants gave results closer in agreement with plate counts than microscopic counts or their modifications tested. The method was considered more convenient than the plate or microscopic count. Differences in the results of other workers are explained by differences in the flora encountered. Thermoduric organisms interfered with the advantages of the resazurin test of Johns and Howson (*E. S. R.*, 83, p. 537) in pasteurized milk.

**New tests on refrigerated milk: Bacteriological analyses in different strata in 10-gallon milk cans as a function of temperature**, J. E. NICHOLAS and T. G. ANDERSON. (Pa. Expt. Sta.). (*Refrig. Engin.*, 44 (1942), No. 1, pp. 23-26, 50, figs. 6).—This paper reports the results of an investigation in which bacteriological analyses were made upon milk cooled (1) with a large amount of initially available refrigeration and the water bath in motion, (2) with a large amount of initially available refrigeration but no motion of the water bath, and (3) with both the milk can and water bath in motion simultaneously. Rates of cooling under each of these sets of conditions are shown, with some other refrigeration data.

When fresh milk was cooled to low average temperatures ranging from 34.5° to 38.1° F. the maximum increase in bacteria was found to be 7,340 and the maximum decrease 4,500. The ratio between the number of organisms in the fresh milk and the cream layer of the cooled milk was found to vary from as low as 5.5 : 1 to as high as 173 : 1. This difference in bacterial numbers results primarily from the filtration and subsequent concentration in the formation of the cream layer. Homogenized milk after cooling exhibited an apparent constant butterfat and bacterial content at all levels in the can.

**The visual mold test under Kansas conditions**, W. J. CAULFIELD, F. E. NELSON, and W. H. MARTIN. (Kans. Expt. Sta.). (*Natl. Butter and Cheese Jour.*, 33 (1942), Nos. 9, pp. 28, 30; 10, pp. 36, 38-40).—Examination of 870 samples of cream collected at random from deliveries at eight Kansas creameries in different seasons showed that excessive amounts of mold as measured by the visual mold test were not a serious problem. This test alone was not a reliable criterion of cream quality. Organoleptic grade showed a pronounced drop in May as contrasted with July, due principally to weed and feed flavors. Of the total samples 26 percent were classified as second grade cream on the basis of organoleptic grade, while 9 percent contained doubtful or excessive amounts of mold, and 4.5 percent showed an excess of 0.80 percent and 21.6 less than 0.41 percent acid. Correlation of the visual mold test with the mold plate counts on these samples showed the visual mold test to be a reasonably accurate indicator of the mold content, and therefore a satisfactory criterion of the cream quality. However, there was little relationship between the development of molds and yeasts and the acidity of the product.

**The role of oxidase-producing bacteria in the development of oxidized flavor in milk**, J. F. CONE and C. J. BARCOCK. (U. S. D. A.). (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 1-6).—There was a complete lack of evidence that oxidase-producing bacteria differ with respect to the cause of oxidized flavor in milk from other bacteria. When nine strains of oxidase-producing organisms were used for inoculation of sterilized milk known to be susceptible to the production of oxidized flavor it was found that no inoculated sample developed a greater intensity of flavor than uninoculated controls. The development of oxidized flavor was markedly or completely inhibited by very heavy inoculations. Studies were made of the oxidized flavor developed at 4°-6° C. in 2 to 4 days' storage of samples with and without 1 p. p. m. of copper. The samples varied from no inoculation or less than 100 to several million organisms per cubic centimeter.

**The prevention of oxidized flavor in milk and ice cream by the use of concentrated milk products**, O. M. RUSSELL and C. D. DAILE. (Pa. Expt. Sta.). (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 25-35).—In confirmation of the findings of Corbett and Tracy (E. S. R., 83, p. 393) and others, certain concentrated milks were found to retard oxidized flavors. High temperature after condensing was more effective in improving the antioxidant properties than similar temperatures before forewarming. Concentrated whole milk had a greater antioxidant effect than concentrated skim milk. When added to fluid milk before pasteurization the concentrated milk was more effective in retarding oxidation than when added after pasteurizing. Small amounts of condensed milk showed antioxidant effects on ice cream when it added only 8.75 percent milk solids-not-fat without contributing any deleterious effect on flavor. The studies were conducted on the influence of dry skim milk and condensed whole and skim milk on the development of oxidized flavors in pasteurized milk, skim milk powder, ice cream mixes, and reconstituted milk after storage up to 17 days and with and without additions of copper.

**Effect of different pasteurization temperatures on keeping quality of butter made from cream containing naturally active lipase**, E. L. JACK, N. P. TARASSUK, and E. L. SCARAMELLA. (Univ. Calif.). (*Natl. Butter and Cheese Jour.*, 33 (1942), No. 12, pp. 16-18, 20).—Lipase activity in butter developed more especially as the period of storage at higher temperatures was prolonged and pasteurization of the cream was delayed. The lipolytic activity was ascertained by changes in surface tension, as indicated by Tarassuk and Smith (E. S. R., 84, p. 665). Special study was made of cream, milk, and butter samples after holding, with and without previous pasteurization.

**Cheese making, J. L. SAMMIS** (*Madison, Wis.: Cheese Maker Book Co., 1942, 10. ed., rev. and ent., pp. 322, [figs. 114]*).—A revision of the book previously noted (*E. S. R.*, 83, p. 104), presenting the modern methods of making different kinds of cheese and descriptions of them, with special consideration of cheese factory operators.

**What can be learned from cheese grading clinics, W. V. PRICE** (*Univ. Wis.*). (*Natl. Butter and Cheese Jour.*, 33 (1942), No. 12, pp. 12-13, 36).—Analyses of cheese scoring in cheese clinics showed that with 181 graders about 3 of their ratings in every 10 samples did not agree with the opinion of the majority. Attention is called to the value of cheese grading clinics, especially for educational purposes.

**Factors affecting Swiss cheese starter activity: Effect of heat treatment and source of milk, M. E. TYLER and H. H. WEISER** (*Ohio State Univ.*). (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 939-948, figs. 5).—Several factors seemed to be involved in the variations which occur in the activity of Swiss cheese starters. There seemed to be justification for the use of heating periods of the mother culture of 2-4 hr. or the use of higher temperatures, since they produced a decreased competitive microbial activity and a decrease in oxidation-reduction potentials. In the conduct of the study milk from different sources was heated at 80° C. for 1, 2, 3, and 4 hr., at 100° for 1, 2, 4, and 5 hr., and at 120° for 15, 30, 45, and 60 min. The milk was then inoculated with 1 cc. of different starter cultures per 100 cc. with incubation at 37°. Heat treatment of the milk at 80° did not affect the biological activity of the bacteria, but there was greater acid development following the longer heating period by most of the Swiss cheese starter cultures. The composition of the milk from different sources had a greater effect on the activity of the starter than heat treatment. In the investigations 18 pure and combined cultures were tested on milk from a single source.

**The effect of copper on lipase activity in Cheddar cheese, I. HLYNKA, E. G. HOON, and C. A. GIBSON** (*Jour. Dairy Sci.*, 25 (1942), No. 11, pp. 923-924).—Copper in amounts of 2 and 5 p. p. m. was not an inactivator of lipase in Cheddar cheese manufacture in 10 comparisons in duplicate with the pancreatic lipase ranging from 0 to 2.5 gm. per 1,000 lb. The copper tended to suppress rancid flavor development in the curd stage, and there was less rancidity of the curd cheese containing copper than when no copper had been added.

**The preparation of crystalline rennin, C. L. HANKINSON** (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 53-62, figs. 2).—As a result of 25 comprehensive fractionation experiments a crystalline rennin was prepared by dialysis and centrifuging which had from 6 to 7 times the activity of commercial rennet extract on a dialyzed-salt-free-dry-weight basis and from 18 to 21 times on a total nitrogen basis. Attention was called to the high sulfur content, the absence of iron, and the questionable contents of phosphorus and copper.

**Study of short-time high-temperature pasteurization of ice cream mix, L. R. DOWD and E. O. ANDERSON** (*Univ. Conn.*). (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 37-46).—In these studies pasteurization of the ice cream mix at 180° F. for 19 sec., before or after homogenization, proved effective in reducing the bacterial colonies and did not cause the development of objectionable flavor. It did not appear to cause significant differences in the viscosity of the mix, bacterial counts, or quality of the ice cream whether pasteurization was conducted before or after homogenization. The body and texture of the finished ice cream was more dependent on the method of freezing than on the method of pasteurizing or length of aging. Mixes were pasteurized by the short-time and holding methods before and after homogenization, and determination was

made of bacterial colonies, phenol value, viscosity, freezing and whipping quality, and body and texture of the ice cream when frozen by the continuous and batch methods.

**Sweeteners for ice cream**, A. H. WHITE (*Canad. Dairy and Ice Cream Jour.*, 21 (1942), No. 10, pp. 44, 46, 48).—Up to 25 percent of the sucrose in ice cream mixes may be replaced by dextrose, other corn products, and by honey without impairing the food value or the quality of the finished product. Some changes in the hardening and holding temperatures may be necessary.

**Comparative standardization of butter, cheese, milk, and ice cream flavor scoring**, G. M. TROUT, P. A. DOWNS, M. J. MACK, E. L. FOUTS, and C. J. BABCOCK (*Jour. Dairy Sci.*, 26 (1943), No. 1, pp. 63-68, figs. 4).—Comparison with the scores of the official judges of the Students' National Contest in the Judging of Dairy Products showed that a selected panel of trained judges could evaluate designated flavor defects comparatively close to those of official judges for the different products. Establishing a standard for flavor defects with a numerical score showed the range of scoring of flavor defects found in butter and ice cream to be more standardized than those for milk and cheese.

### VETERINARY MEDICINE

[Contributions on veterinary medicine] (*U. S. Livestock Sanit. Assoc. Rpt.*, 45 (1941), pp. 8-58, 63-110, 118-141, 150-191, 193-194, figs. 7).—Contributions presented at the annual meeting of the association in 1941 (E. S. R., 85, p. 664) include: Personal Survey of Wartime Animal-Disease Control in Great Britain, by A. Eichhorn (pp. 8-13) (U. S. D. A.); Bovine Tuberculosis Eradication in the United States and Its Resulting Beneficial Effects on Human Health, by J. A. Myers (pp. 14-21) (Univ. Minn. et al.); Equine Encephalomyelitis and Its Control, by R. A. Kelsner (pp. 22-27); Swine Influenza Experiments, by J. P. Scott (pp. 28-37) (U. S. D. A. et al.); Immunological Studies With Hog Cholera Tissue Vaccine (pp. 38-43) and Cell Changes in the Gall Bladder as an Aid in the Diagnosis of Hog Cholera (pp. 44-47), both by W. H. Boynton, G. M. Woods, F. W. Wood, and N. H. Casselberry (Univ. Calif. et al.); Equine Breeding Hygiene, by W. W. Dimock (pp. 51-58) (Ky. Expt. Sta.); Factors Affecting the Viability of Strain 19 *Brucella* Vaccine, by E. L. Love and C. K. Mingle (pp. 65-72) (U. S. D. A.); Bang's Vaccination—a Public Health Problem, by M. M. Rabstein (pp. 73-75); Undulant Fever, by H. M. Guilford (pp. 76-79); Report on Bovine Brucellosis Work, Including Calfhood Vaccination, by J. R. Mohler and A. E. Wight (pp. 80-86) (U. S. D. A.); Forum on Bang's Disease by W. Giltner et al. (pp. 89-110); Chemotherapy in the Control of Avian Coccidiosis, by P. P. Levine (pp. 118-120); A Plan to Combat Avian Tuberculosis Infection as Followed in Michigan, by C. H. Clark (pp. 121-126); The Reasons for Failures in Immunization Against Laryngotracheitis and Pox, by F. R. Beaudette (pp. 127-141) (N. J. Stas.); The Value of Blood Examinations in the Diagnosis of Bovine Tuberculosis, by R. A. Hendershott and C. B. Johnston (pp. 157-169); Time Has Proved the Efficiency and Value of Bovine Tuberculosis Eradication Work, by A. E. Wight (pp. 170-173) (U. S. D. A.); The No-Visible-Lesion Case Problem in Tuberculosis Eradication, by W. A. Hagan (pp. 174-179) (Cornell Univ.); and Studies on the Treatment of Wounds in Experimental Rabies, by H. J. Shaughnessy and J. Zichis (pp. 182-185).

Among the reports of committees presented are those on transmissible diseases of swine (pp. 48-50), meat and milk hygiene (pp. 63-64), Bang's disease (brucellosis) (pp. 87-88), transmissible diseases of poultry (pp. 150-154), parasitic diseases (pp. 155-156), tuberculosis (pp. 180-181), rabies (pp. 186-188), miscellaneous transmissible diseases (pp. 188-191), and biologics (pp. 193-194).

**Microbiology and man**, J. BIRKELAND (*New York: F. S. Crofts & Co., 1942, pp. X+478, figs. 35*).—The fundamentals of microbiology (pp. 1–130), infection and resistance (pp. 131–179), common infectious diseases (pp. 180–364), and the microbiology of food, milk, water, sewage, and soils (pp. 365–441) are considered in this textbook. The class schizomycetes (pp. 443–454), glossary (pp. 455–461), and a four-page list of references are included in an appendix.

**Demonstration of serological types within the nonhemolytic *Pasteurella***, P. A. LITTLE and B. M. LYON (*Amer. Jour. Vet. Res., 4 (1943), No. 10, pp. 110–112*).—It was demonstrated in serological studies of 30 strains of nonhemolytic *Pasteurella* that these organisms could be definitely classified into 3 distinct types. The type specificity, virulence, and host origin of these strains were found to be unrelated. The protective property of therapeutic anti-*Pasteurella* serums was found to be correlated with the type specificity of the strains included in the immunizing mixtures. Anti-*Pasteurella* serums representing 3 serological types were the only serums which would consistently protect mice against all of the virulent, nonhemolytic *Pasteurella* studied.

**Studies on the eggs of *Ascaridia galli* and *Heterakis gallinae***, R. O. CHRISTENSON, H. H. EARLE, JR., R. L. BUTLER, JR., and H. H. CREEL. (Ala. Expt. Sta.). (*Amer. Micros. Soc. Trans., 61 (1942), No. 2, pp. 191–205, figs. 10*).—Report is made of studies of the morphology, intracapsular development, thermal death points, effects of certain chemicals, and the longevity of the eggs of these nematodes in vitro.

**In vitro and in vivo studies of gramicidin, tyrothricin, and tyrocidine**, H. J. ROBINSON and O. E. GRAESSLE (*Jour. Pharmacol. and Expt. Ther., 76 (1942), No. 4, pp. 316–325*).—"Tyrocidine and tyrothricin appear to exert a marked bactericidal action on aerobic and anaerobic gram-positive bacteria in the absence of blood or serum. Under similar conditions gramicidin appears to be primarily bacteriostatic. In the presence of blood or serum, tyrocidine and tyrothricin lose their bactericidal properties whereas gramicidin retains its bacteriostatic properties. Under these conditions tyrothricin becomes primarily bacteriostatic, apparently by virtue of its gramicidin content. In vivo results indicate that when mice are infected and treated by intraperitoneal injection gramicidin and tyrothricin are active whereas tyrocidine is not. Gramicidin or tyrothricin are only effective when given in direct contact with the infecting bacteria. No protection was afforded to mice infected by intraperitoneal injection when treatment was given by oral, subcutaneous, or intravenous administration. Likewise, mice infected by vein were not protected by intraperitoneal treatment."

**Anthrax: A review of sixty cases, with a report on the therapeutic use of sulfonamide compounds**, H. GOLD (*Arch. Int. Med., 70 (1942), No. 5, pp. 785–821, figs. 13*).—A review is given of 60 cases of anthrax, and the sources of infection, yearly occurrence, distribution, clinical course, and methods of treatment are considered. In 21 cases treated with antianthrax serum 1 death occurred. To secure recovery large amounts of serum (200 to 2,200 cc.) were administered intravenously, an optimum dose sufficient to control the edema having been required in each case. Neoarsphenamine given in addition to serum was found to be of little or no benefit. In 42 cases of anthrax, treatment was with sulfonamide compounds, with excellent results in 39 cases. Sulfapyridine was found to be the most effective sulfonamide compound, followed by sulfathiazole and sulfadiazine, respectively. Because of complications arising from the use of sulfapyridine, sulfathiazole is considered the drug of choice, of which large doses should be given until edema is controlled. It is concluded that sulfonamide compounds are a safe and reliable substitute for antianthrax serum. They are easy to administer; their use materially shortens the period of hospitalization and disability; and they are economical.

**Prophylactic effect of sulfaguanidine against ulcerative cecitis in rats,** A. L. BLOOMFIELD and W. LEW (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 363-368, fig. 1).—The addition of 0.5 percent of sulfaguanidine to the diet of a rat colony, in which the majority of the animals developed lesions of cecitis, produced no deleterious clinical effect nor visible gross lesions and even in the small doses used had a striking prophylactic effect against the development of ulcerative cecitis.

**Prevention by succinyl sulfathiazole of ulcerative cecitis in rats,** A. L. BLOOMFIELD and W. LEW (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 28-29).—In continuation of the work with sulfaguanidine above noted, succinyl sulfathiazole incorporated in the stock ration was shown to prevent completely the development of ulcerative cecitis in rats.

**Culex tarsalis Coq. a proven vector of St. Louis encephalitis,** W. M. HAMMON and W. C. REEVES. (Univ. Calif. et al.) (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 142-143).—In continuation of the work in the Yakima Valley, Wash., in 1941 (E. S. R., 87, p. 717; 88, p. 385) in which *C. tarsalis* was thrice found infected with the virus of St. Louis encephalitis, experiments are reported which have led to the conclusion that this species is a natural vector. This is said to be the first instance in which a mosquito has fulfilled the three criteria for incrimination as a vector in respect to St. Louis encephalitis virus. It is pointed out that the northern house mosquito has been shown to be capable of transmitting this virus in the laboratory, and that *C. coronator* Beyer has now been demonstrated to do so. In addition, these experiments have demonstrated that the chicken may serve as a satisfactory reservoir of virus. "This is undoubtedly shared by other birds, for we have previously shown that virus may be isolated from the blood of a dove following the bite of *C. pipiens*<sup>3</sup> and unpublished work indicates that ducks may serve as reservoirs."

**Encephalitis: Eastern and western equine and St. Louis types, as observed in 1941 in Washington, Arizona, New Mexico, and Texas,** W. M. HAMMON. (Univ. Calif.). (*Jour. Amer. Med. Assoc.*, 121 (1943), No. 8, pp. 560-564).—In reporting further (see above) it is suggested that eastern and western equine and St. Louis encephalitis be classed as members of a group to be called the arthropod-borne virus encephalitides. The data presented are based upon a study made of outbreaks occurring in 1941 in Washington, Arizona, New Mexico, and Texas. Evidence was obtained indicating the presence of three and possibly four encephalitic viruses in Texas and of at least two in each of the other areas (two isolated from the Yakima Valley).

**Complement fixation with the neurotropic viruses,** W. P. HAVENS, JR., D. W. WATSON, R. H. GREEN, G. I. LAVIN, and J. E. SMADEL (*Jour. Expt. Med.*, 77 (1943), No. 2, pp. 139-153, fig. 1).—"Antigens capable of fixing complement specifically with the appropriate antibodies have been prepared from brain tissue of hamsters and mice infected with the viruses of St. Louis, Japanese, western, and eastern encephalitis and with the West Nile virus. The antigens were freed of the material which reacts with normal serum by means of centrifugation at relatively high speed. In addition, the infectivity of the preparation was destroyed by irradiation with ultraviolet light. Cross reactions were demonstrated by means of the complement-fixation technic with materials from animals infected with the viruses of eastern and western equine encephalitis. No relationship was detectable by this procedure between St. Louis, Japanese, and West Nile viruses. These findings emphasize the need for further investigation and correlation of the immunological reactions of the groups of neurotropic viruses, since the

<sup>3</sup> Soc. Expt. Biol. and Med. Proc., 50 (1942), No. 1, pp. 125-128.

equine agents are apparently unrelated when studied by neutralization and cross-immunity tests while these methods provide evidence of the presence of common antigenic structures in the St. Louis, Japanese, and West Nile agents."

**Studies on John's disease: Reactions to Johnin in sensitized guinea pigs,** H. KONST and E. A. WATSON (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 34-44, figs. 8).—The relative effect of various routes and vehicles in the sensitization of guinea pigs to Johnin by the injection of John's bacilli was examined in approximately 1,900 intradermal tests with Johnins prepared in the Animal Diseases Research Institute in Quebec. The intraperitoneal application of a comparatively small dose of John's bacilli in animals treated 48 hr. previously with a suspension of Ca-phosphate introduced by the same route gave the most favorable results. Guinea pigs sensitized by this method were used with success for potency-determinations of Johnin purified protein derivative in intradermal tests carried out along the lines followed in the standardization of tuberculin.

**Serological identification of Salmonella cultures,** P. R. EDWARDS and D. W. BRUNER (*Kentucky Sta. Cir.* 54 (1942), pp. 35).—Variational phenomena which affect *Salmonella*, antigenic analysis, biochemical reactions, and standard strains of *Salmonella* cultures, of which there are 164 available for distribution, are reported upon.

**Can larvae of Cochliomyia americana C. and P. mature in carcasses?** A. L. BRODY and E. F. KNIPLING. (U. S. D. A.). (*Jour. Parasitol.*, 29 (1943), No. 1, pp. 59-60).—Observations on the development of screwworm larvae of various ages in carcasses screened and unscreened from attack by carrion-feeding insects are recorded in table form. It was found that larvae would continue to develop in carcasses even outdoors, but unless they were mature by the third day after death of the host they had little chance of continuing development, owing to competition with the many carrion-feeding larvae. Larvae 24 hr. old and in the early second stage were observed to molt to the third stage by the third day after death of the host, but even if recovered these young third-stage larvae never developed to adults. Under outdoor conditions carrion-feeding larvae usually overran the carcass by the third day after death of the animal, and screwworm larvae could no longer be observed even though they had been seen as vigorously active 2 days after death of the host.

**Studies on the hemorrhagic sweet clover disease, IV-VII.** (Wis. Expt. Sta. coop. U. S. D. A.). (*Jour. Biol. Chem.*, 138 (1941), Nos. 1, pp. 21-33, figs. 3; 2, pp. 513-527, fig. 1; pp. 529-534, fig. 1; 142 (1942), No. 2, pp. 941-955, figs. 5).—A continuation of these studies (E. S. R., 86, p. 249), part 3 of which has not been published, is presented as follows:

IV. *The isolation and crystallization of the hemorrhagic agent,* H. A. Campbell and K. P. Link (pp. 21-33).—"The hemorrhagic agent in spoiled sweetclover hay (*Melilotus alba*) has been isolated in a pure state, m. p. 288°-289°, from experimentally produced spoiled hays as well as from hays that killed cattle in agricultural practice. The substance has the empirical formula  $C_{15}H_{12}O_6$ . It is optically inactive. There are two acidic hydroxyls in the molecule. The acidity of the pure substance falls between that of the phenols and the carboxylic acids. A crystalline dimethyl ether  $C_{15}H_{14}O_4(OCH_3)_2$  with a melting point of 168°-170° (physiologically inactive) has been prepared by methylation with diazomethane. In the pure state the substance has a low solubility in the ordinary organic solvents. It is insoluble in acid media. Basic solvents and dilute alkali effect solution readily (salt formation). The substance could not be characterized or identified on the basis of its behavior toward the usual identification reagents. Its occurrence in nature has not previously been reported. One and five-tenths mg. of the crystalline hemorrhagic agent cause

approximately the same reduction in the prothrombin level or activity of the plasma of standardized susceptible rabbits in 40 hr. as 50 gm. of the standard spoiled hay sample. Spoiled sweetclover hays produced experimentally from *M. alba* and those realized in agricultural practice contain approximately 0.003 percent of the hemorrhagic agent on the dry substance basis. The over-all yield of the substance in a fractionation scheme involving 16 steps approximates 66 percent of the quantity present."

V. *Identification and synthesis of the hemorrhagic agent*, M. A. Stahmann, C. F. Huebner, and K. P. Link (pp. 513-527).—Reporting further, proof is presented through degradation reactions and by synthesis that the hemorrhagic agent,  $C_{10}H_{12}O_4$ , m. p.  $288^{\circ}$ – $289^{\circ}$ , present in improperly cured hay made from the common sweetclovers (*M. alba* and *M. officinalis*) is the dicoumarin, 3,3'-methylenebis(4-hydroxycoumarin). The chemical and physical properties of the naturally occurring and the synthetic products have been shown to be identical. The synthetic product has been shown to parallel the naturally occurring product in its capacity to reduce the prothrombin level (or activity) of standardized susceptible rabbits. The hemorrhagic condition characteristic of the sweetclover disease has been produced in various species of experimental animals by continued feeding of the synthetic 3,3'-methylenebis(4-hydroxycoumarin). The bearing of this study on the objectives of the plant geneticist to breed a low coumarin line of sweetclover and the possible value of the hemorrhagic agent to the physiologist and hematologist are discussed.

VI. *The synthesis of the  $\delta$ -diketone derived from the hemorrhagic agent through alkaline degradation*, C. F. Huebner and K. P. Link (pp. 529-534).—It has been found that the " $\delta$ -diketone,  $C_{17}H_{16}O_4$ , formed in the degradation of the hemorrhagic agent from spoiled sweetclover hay, 3,3'-methylenebis(4-hydroxycoumarin), with 10 percent sodium hydroxide is 1,3-disalicylpropene. The  $\delta$ -diketone was synthesized from phenyl glutarate via the Fries rearrangement. Its dimethyl ether,  $C_{17}H_{16}O_2(OCH_3)_2$ , was prepared by condensing *o*-methoxybenzoylacetate ester with methylene iodide and subjecting the intermediate dicarboxylic ester to hydrolysis and decarboxylation."

VII. *The effect of 3,3'-methylenebis (4-hydroxycoumarin) on the prothrombin time of the plasma of various animals*, R. S. Overman, M. A. Stahmann, W. R. Sullivan, C. F. Huebner, H. A. Campbell, and K. P. Link (pp. 941-955).

*Mechanism of bradycardia in rats with thiamine deficiency*, D. McEachern and D. Brophy (*Soc. Expt. Biol. and Med. Proc.*, 51 (1942), No. 1, pp. 75-76).—The bradycardia of thiamine-deficient rats disappears when the auricles are isolated in vitro, this condition probably being of neurogenic origin.

*The effect of sulfonamides on the urinary tract in small animals*, E. C. Kuehn (*North Amer. Vet.*, 24 (1943), No. 1, pp. 30-33).—While sulfathiazole is the drug of choice in combating urinary tract infections, sulfanilamide even in relatively low concentration is effective in curing most of them.

*Infection of newborn Syrian hamsters with the virus of mare abortion (Dimock and Edwards)*, K. Anderson and E. W. Goodpasture (*Amer. Jour. Pathol.*, 18 (1942), No. 4, pp. 555-561, pl. 1).—Record is made of morphological evidence of the experimental transmission of infection by mare-abortion virus (*Brucella abortus equi*) through three serial passages in newborn hamsters. It was found in the course of the investigation that this virus is infectious likewise for human amniotic epithelium, in view of which it must be considered a potential agent of disease in human beings.

*The effect of Brucella abortus on the bovine udder and its secretion*, A. C. Emminger and O. W. Schalm. (Univ. Calif. coop. U. S. D. A.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 100-109, figs. 7).—The authors have found

that the quality of milk from *B. abortus*-infected quarters is not significantly different from that of the normal product. Visible particles were not observed in the foremilk, and the pH, chloride content, leucocyte count, and saprophytic bacterial count were well within normal limits. A careful examination of the entire parenchyma of each infected quarter failed to reveal gross lesions. Histopathological changes were observed, however, in 17 of 19 quarters that had harbored *B. abortus* for periods varying from 16 to 324 days. These consisted of an exudation of neutrophils into the alveolar lumen, associated with fatty degeneration of the alveolar epithelium with a tendency toward desquamation of epithelial cells. More commonly, however, the microscopic pathology was characterized by a dense accumulation of lymphocytes and plasma cells in the inter-alveolar tissues. Epithelioid cells and giant cells were found in some instances. In the larger inflammatory foci, proliferation of the connective tissue elements occurred. In some instances the supramammary lymph nodes also contained histopathological changes.

**Sulfaguanidine therapy in experimental bovine coccidiosis, D. C. BUGHTON.** (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 66-72, figs. 2).—The results of the experimental treatment of experimental infections of bovine coccidiosis with sulfaguanidine are reported. "Favorable results were obtained in the case of *Eimeria bovis* infections when the drug was given daily (1) at the rate of 0.1 gm. per kilogram of body weight for a 3-week period beginning 2 days after inoculation and (2) in 5-gm. doses for an 8-day period beginning 13 days after inoculation. Treatment of *E. bovis* infections for 8-day periods begun 3 days before and 5 days after inoculation was not effective. Marked differences between treated and control infections were not obtained in the case of *E. alabamensis*." The relation between successful treatment and size of coccidial population is discussed. Distinctive features of the asexual stages of *E. alabamensis* and *E. bovis* are pointed out, and their possible significance in the present work suggested. It is concluded that sulfaguanidine gives promise of being useful against certain types of bovine coccidiosis.

**Eimeria wyomingensis, a new coccidium from cattle, H. HUIZINGA and R. N. WINGER.** (Wyo. Expt. Sta.). (*Amer. Micros. Soc. Trans.*, 61 (1942), No. 2, pp. 131-133, figs. 2).—Description is given of a new species of coccidium, from the alimentary tract of a calf, which has been found to be widely distributed in the area surrounding Laramie, Wyo.

**Infectious bovine mastitis.—VIII, The control of Streptococcus agalactiae mastitis by a segregation program based on periodic laboratory tests, W. N. PLASTRIDGE, E. O. ANDERSON, and F. J. WEIRETHER [(Connecticut) Storrs Sta. Bul. 240 (1942), pp. 54, fig. 1].**—This further contribution (E. S. R., 82, p. 103), presented with a list of 31 references to the literature, describes a procedure for the routine laboratory testing of milk samples for mastitis and the identification of mastitis organisms. Observations of five experimental herds employed in developing a control program based in segregation are reported under headings of laboratory procedures (pp. 6-20), establishment and maintenance of herds free from *S. agalactiae* (pp. 20-36), and *S. agalactiae* infection in first calf heifers (pp. 36-39). Practical information on the segregation program for bovine mastitis control appears as an appendix.

It is concluded that "with proper segregation, sanitation, herd management, and laboratory tests made at intervals of 3 to 4 months, the annual spread of *S. agalactiae* infection may be kept below 10 percent, and that if this is done the disease can eventually be eliminated from the average herd."

**The preparation and use of sulfanilamide in iodized mineral oil for mastitis, D. A. SANDERS.** (Fla. Expt. Sta.). (*North Amer. Vet.*, 24 (1943), No. 1,

pp. 40-42).—A description is given of the process of suspending powdered sulfanilamide in iodized mineral oil, which results in a preparation suitable for introduction into the udder by way of the teat canal. At the Florida Station this preparation has proved to be a valuable chemotherapeutic agent in the treatment of udder infections. See also earlier notes (E. S. R., 86, p. 531; 88, pp. 101, 681).

**The value of udder infusion in the treatment of streptococcal mastitis in cows,** S. J. EDWARDS (Vet. Rec., 54 (1952), No. 48, pp. 499-500).

**Effect of injections of Novoxil on the bovine udder infected with mastitis streptococci,** G. R. SPENCER and B. A. BEACH. (Wis. Expt. Sta.). (Amer. Jour. Vet. Res., 4 (1943), No. 10, pp. 45-49, 50, figs. 4).—The treatment of 3 quarters of the udders of 2 cows infected with *Streptococcus agalactiae* with Novoxil produced an acute clinical inflammation, with secretions containing abnormally large amounts of catalase and chlorides. The number of streptococci eliminated was reduced markedly, but a few were found in the secretion of all 3 quarters 16 days later, just before the cows were slaughtered. Post-mortem gross and histopathologic examinations disclosed acute inflammatory changes which were more severe in the 2 quarters clinically abnormal before treatment than in the quarter which was giving normal milk prior to the injections. Injection of 21 dry quarters of 6 infected cows resulted in the elimination of the infection in 11 quarters, with very little or no inflammation produced.

**Infection of the bovine udder by Pasteurella septica,** I. W. BURTON and J. W. Emslie (Vet. Rec., 54 (1942), No. 39, pp. 387, 388).—A bipolar organism isolated from the mammary secretion of a cow which produced indole, fermented sorbitol, was not hemolytic, but was highly virulent for the rabbit is described under the name *P. septica*.

**Establishment of infection with Trichomonas foetus in bulls by experimental exposure,** D. M. HAMMOND and D. E. BARTLETT. (U. S. D. A.). (Amer. Jour. Vet. Res., 4 (1943), No. 10, pp. 61-65, fig. 1).—In the experimental work reported 5 bulls were exposed to *T. foetus* by introducing into the prepuce cotton pledgets soaked in vaginal washings from experimentally infected heifers and cows. Two became infected; 3 remained negative after a number of exposures by this and other methods. Thirteen bulls were exposed a total of 154 times by various methods not involving the use of pledgets. None became infected. No obvious clinical symptoms associated with trichomoniasis were observed in the experimentally infected bulls. Each bull was able to transmit infection to susceptible cows by service. The results indicate that there are distinct individual differences in natural resistance of bulls to infection with *T. foetus*.

**The eradication of bovine tuberculosis,** E. G. HASTINGS. (Wis. Expt. Sta.). (Jour. Dairy Sci., 25 (1942), No. 12, pp. 1057-1065).—A review of the first 25 years of work with bovine tuberculosis eradication.

**A preliminary report on a treatment for fleece-worm infestations in sheep,** E. F. KNIPLING. (U. S. D. A.). (Jour. Econ. Ent., 35 (1942), No. 6, pp. 896-898).—In work aimed at the development of a combination treatment that would kill the larvae and at the same time provide protection against reinfection, a high degree of protection was obtained with all the materials. Only one reinfestation occurred among 33 animals treated with the diphenylamine solution, and none occurred among animals treated with other combinations. When mixtures of benzene and diphenylamine or diphenylene oxide solutions containing turkey-red oil or Wetsit Concentrated were used, no reinfestations occurred. In addition to tests on artificially induced infestations, 14 natural infestations were treated with the combinations of benzene and diphenylamine or diphenylene oxide. No reinfestations occurred. The results indicate that benzene containing

approximately 15 percent of diphenylamine is an effective and convenient treatment for fleece worm infestations in sheep. Diphenylene oxide and *p*-nitrophenetole are indicated to be equal or superior to diphenylamine in preventing reinfestations, but since diphenylamine is used in the treatment of screwworm infestations this chemical would be most practical.

**The worm burden of sheep on improved and unimproved hill pastures,** G. REES (*Jour. Anim. Ecol.*, 11 (1942), No. 2, pp. 198-204, pl. 1, figs. 2).

**Identification of eggs of nematodes parasitic in domestic sheep,** K. C. KATES and D. A. SHORB. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 54-60, figs. 14).—The authors present photomicrographs of eggs of 14 common species of nematodes, together with descriptions of eggs of 15 species, and make suggestions which may assist in the accurate identification of these eggs.

**Preliminary studies on the use of phenothiazine in the control of lung worms in sheep and goat,** D. F. and M. W. EVELETH and R. GIFFORD. (Ark. Expt. Sta.). (*Vet. Med.*, 38 (1943), No. 2, pp. 63-66, figs. 4).—Preliminary studies of Arkansas sheep flocks indicate that lungworms are serious parasites in that State. The intratracheal injection of phenothiazine in glycerol and alcohol has been found to kill lungworms in vivo with a minimum of damage to the host. It is not advised to use intratracheal injections in sheep or goats suffering from advanced pneumonia or caseous lymphadenitis with or without pneumonic symptoms. Where reinfestation is taking place constantly it will probably be necessary to treat at frequent intervals.

**Some procedures that affect the bacteriological quality of goat milk,** C. S. BRYAN. (Mich. Expt. Sta.). (*Dairy Goat Jour.*, 20 (1942), No. 9, pp. 1, 3-7, figs. 13).—In annual examinations for 3 yr. of the milk and udders of the lactating goats in 27 herds containing 619 animals 1.6 percent were found to be affected with streptococcic mastitis. Two of the animals were eliminated from the herd. One recovered after treatment by infusing each half of the udder with a water solution containing 150 mg. of tyrothricin. Six recovered without treatment, and only 1 remained permanently infected. Staphylococcic mastitis was found present in 5 of the goats, 3 of which were eliminated from the herd, and the remaining animals made uneventful recoveries. An additional 10 were found to have noninfectious mastitis. In determinations made of the physical condition of the udder of each goat 92 percent of those without mastitis had udders that were considered normal on physical examination, an additional 4 percent had atrophied portions of the udder, and 4 percent more had indurated udders. Of the goats with staphylococcic infection of the udders, only 20 percent had normal udders, and only 7 percent of those with streptococcic mastitis had udders that were normal on physical examination. It was found that only 4 percent of the goats with no mastitis produced milk with a count of more than 1,000, while 12 percent of those with staphylococcic mastitis and 50 percent of those with streptococcic mastitis yielded milk with a count of more than 1,000. The data obtained are reported in detail in seven tables.

**Sulfaguanidine in the treatment of infectious enteritis in swine,** H. C. H. KERKAMP and M. H. ROEPKE. (Minn. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 3-14).—The experimental work conducted with swine is divided into four parts, the first of which deals with a series of controlled experiments on the use and value of sulfaguanidine from the standpoint of the therapy of enteric infections. Part 2 concerns a series of cases treated under field conditions; part 3 pertains to a study of the blood, fecal, and urine concentrations of the drug when administered at different dose levels for various lengths of time; and part 4 to matters of drug tolerance and toxicity. The studies have indicated that sulfaguanidine possesses considerable merit as a therapeutic agent in the

treatment of the infectious enteric complex in swine commonly grouped under such terms as infectious enteritis, necrotic enteritis, etc. Sulfaguanidine when administered morning and evening as a suspension in a small amount of mash or thick swill at the rate of 0.75 to 1.5 gm. per 10 lb. of body weight per day gave favorable results. Those animals which would not eat were given the drug by capsule until they consumed sufficient food to permit the administration of the drug in a portion of the feed. In order to obtain high fecal levels of the drug as early as possible, particularly in the acute cases, the first dose given was always twice the usual dose of the drug. As a rule, the physical condition of the animals began to show improvement by the third to fifth day and the character of the feces returned to normal by the fourth to sixth day. Usually the drug was administered for a period of 6 to 8 days, which generally included a few days after the stools had returned to a normal consistency. A few animals treated with sulfaguanidine have shown remissions. It was not determined whether these remissions were due to reinfections or to the failure of the drug to eliminate the causative organisms of the original disease.

**Isolation of western equine encephalomyelitis and hog-cholera viruses from supposedly hog-cholera immune swine.** S. H. McNUTT and A. PACKER (Iowa State Col.). (*Vet. Med.*, 38 (1943), No. 1, pp. 22-25).—Report is made of the isolation of these viruses during the examination of 2 pigs, both from a herd of 56. That hogs are resistant to western equine encephalitis is indicated by failure to produce apparent symptoms in artificially exposed hogs, except in 1 baby pig, and by failure, except in one instance, to isolate the virus from the tissues of exposed individuals. That hogs may be infected under certain circumstances with western equine encephalomyelitis is shown by the isolation of the virus from a pig, death, and reisolation of the virus from 1 artificially exposed baby pig and an increased neutralizing effect of the serums of pigs which had been exposed to the virus.

**The swine lungworm as a reservoir and intermediate host for swine influenza virus, III, IV.** R. E. SHOPE (*Jour. Expt. Med.*, 77 (1943), No. 2, pp. 111-138).—Two further contributions are presented (*E. S. R.*, 85, p. 823).

III. *Factors influencing transmission of the virus and the provocation of influenza* (pp. 111-126).—Report is made of the results of a 3-yr. study of the lungworm as intermediate host for the swine influenza virus in which 98 transmission experiments, using 216 swine, were conducted. Negative results were obtained in 50, while in the remaining 48 transmission of swine influenza virus by way of the lungworm was demonstrated in 1 or more animals of each experiment. Irregularities in the results appear to be due not so much to lack of transmission of masked virus by the lungworm as to failure to evoke its pathogenic capabilities.

"The stimulus of choice that was most successful in the provocation of swine influenza consisted of multiple intramuscular injections of *H[emophilus] influenzae suis*. In several experiments pigs developed swine influenza virus infections 9 to 17 days after infestation with infected lungworms in the absence of any known provocative stress. In these instances an immune response of the swine to the lungworms themselves is suspected of having furnished the provocation. During May, June, July, and August swine prepared by the ingestion of lungworms carrying virus were absolutely refractory to the provocation of influenza, and they were relatively refractory in September and October. The masked virus was activated most readily during the first 4 mo. of the year. In a single experiment we succeeded in demonstrating by direct means the presence of swine influenza virus in the neighborhood of lungworms at the base of the lung at a time when the virus was not demonstrable anywhere else in the respiratory tract. Masked swine influenza virus was found to be present in lungworm ova

obtained either from the respiratory tracts or the feces of infected swine. In a number of instances masked swine influenza virus has been found to persist for over a year in lungworm larvae within the earthworm intermediate hosts, and in one case its presence was demonstrated after 32 mo. Two varieties of a single species of earthworm, namely, *Allolobophora caliginosa* f. *typica* (Savigny) and *A. caliginosa* f. *trapezoides* (Dugès), have been found separately capable of serving as intermediate hosts for virus-infected lungworms. Lungworm ova obtained from convalescent swine which are no longer carrying swine influenza virus in infectious form in their respiratory tracts contain masked virus."

IV. *The demonstration of masked swine influenza virus in lungworm larvae and swine under natural conditions* (pp. 127-138).—The presence of masked swine influenza virus was demonstrated in lungworm larvae from earthworms dug on midwestern farms. Swine influenza virus infections were provoked in 2 of 3 swine obtained from an Iowa farm during an interepizootic period. The evidence presented has been interpreted as indicating that the swine lungworm is the reservoir and intermediate host for swine influenza virus in the field. A concept of the epidemiology of swine influenza in which the causative virus is represented as being maintained and disseminated in a masked form by its lungworm intermediate host is presented.

**The pathology of equine influenza**, T. C. JONES and F. D. MAURER (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 15-31, figs. 25).—Report is made of a study based upon 150 post-mortem examinations selected from more than 4,000 cases of equine influenza available for clinical observation at a remount depot.

**Gastralgia in a horse due to bot infestation**, P. C. UNDERWOOD and G. DIKMANS. (U. S. D. A.). (*Vet. Med.*, 38 (1943), No. 1, pp. 12-13, figs. 2).—Report is made of a case of gastralgia in a horse, subsequently terminating in a ruptured stomach and death of the animal, due to heavy infestation of botfly larvae.

**Histologic adaptation of the virus of fox encephalitis**, J. C. BARTON and R. G. GREEN. (Univ. Minn. et al.). (*Amer. Jour. Hyg.*, 37 (1943), No. 1, pp. 21-36).

**Coccidioidomycosis in wild rodents—a method of determining the extent of endemic areas**, C. W. EMMONS (*Pub. Health Rpts. [U. S.]*, 58 (1943), No. 1, pp. 1-5).

**The life cycle of four intestinal coccidia of the domestic rabbit**, R. L. RUTHERFORD (*Jour. Parasitol.*, 29 (1943), No. 1, pp. 10-32, figs. 113).—Studies made of the endogenous cycles of the four species of intestinal *Eimeria* found in the domestic rabbit, namely, *E. irresidua*, *E. magna*, *E. media*, and *E. perforans*, show each to produce two types of merozoites. The completion of their endogenous cycles requires from 9 to 10 days for *E. irresidua*, 7 for *E. magna*, 6 for *E. media*, and 5 for *E. perforans*.

**A bioassay technique for anthelmintics**, J. H. WHITLOCK and C. I. BLISS. (Kans. Expt. Sta.). (*Jour. Parasitol.*, 29 (1943), No. 1, pp. 48-58, figs. 3).

**Dosage-mortality curves** were determined experimentally for the toxicity of carbon tetrachloride to artificial inoculations of *Nippostrongylus muris* in albino rats. When percentage kills were transformed to probits, the observations could be plotted linearly against the dose or log-dose, a relation similar to that observed for anthelmintics on parasitic nemas in vitro and for lethal drugs on other multicellular organisms. Since the percentage mortality was estimated from parallel untreated control groups, the standard calculation required certain modifications, which are described. The toxicity of the drug to albino rats was determined with a similar dosage-mortality curve, so that the dose of carbon tetrachloride killing predetermined percentages of both parasite and host could

be computed with a measurable precision. Based on these curves, two methods for evaluating anthelmintics are proposed.

**Characteristics of the population available for bioassay of anthelmintics in *Nippostrongylus muris* infection in albino rats,** J. H. WHITLOCK. (Kans. Expt. Sta.). (*Jour. Parasitol.*, 29 (1943), No. 1, pp. 42-47).—A standard technic for inoculating rats with uniform doses of *N. muris* is described and its error determined. Analysis of data from 110 rats divided into 11 groups and infected with uniform doses of infective larvae of *N. muris* revealed two types of variation in numbers of worms establishing themselves: (1) A within-test variation which was larger than the binomial but uniform and approximating the normal curve and (2) a between-test variation which was many times larger than the above and which was unpredictable. The results of these experiments show that under adequate statistical and biological control it is possible to predict with workable accuracy the number of worms in rats of a treated group expected in the absence of treatment from the number of worms in a parallel control group. Although part of the variation between and within separate tests was due to variation in the numbers of infective larvae injected into the rats, this did not explain the wide variation observed. More probably it was largely due to an interaction between host and parasite which has yet to be explained.

**Diseases of chickens,** J. R. BEACH and M. A. STEWART (*California Sta. Bul.* 674 (1942), pp. 151, figs. 56).—This practical contribution, which supersedes the publication previously noted (E. S. R., 75, p. 546), brings together the present knowledge of diseases of the domestic fowl and means for their control.

**Control of respiratory diseases in poultry,** H. VAN ROEKEL. (Mass. Expt. Sta.). (*Northeast. Poultryman*, 35 (1942), No. 6, pp. 14-15).

**A superior medium for the hemophilic fowl coryza bacillus,** D. W. GREGORY. (N. C. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 32-33).—The poor growth of the fowl coryza bacillus obtained in and on the commonly used media led to the search for a more satisfactory medium. Of those tested, the blood broth and liver filtrate gave good results, and the chicken infusion plus raw potato gave excellent results.

**Sulfathiazole for colds in chickens,** V. HELMAN (*Vet. Med.*, 38 (1943), No. 1, pp. 26-28, figs. 3).

**Avian pneumo-encephalitis,** J. R. BEACH. (Univ. Calif.). (*Vet. Med.*, 38 (1943), No. 2, p. 46).—This is a partial summary of the results of an investigation of the widely distributed avian pneumoencephalitis in poultry which has been found to be due to a newly identified virus and is not related to the western equine or the St. Louis types of infectious encephalomyelitis. In hens affected with the disease the production of eggs practically ceased and had not returned after several months. Recovered chicks may be virus carriers. The mortality of the disease ranges from none to 21 percent.

**Synergistic action of *Hemophilus influenzae suis* and the swine influenza virus on the chick embryo,** F. B. BANG (*Jour. Expt. Med.*, 77 (1943), No. 1, pp. 7-20, pls. 2).—It was found that the synergistic effect of *H. influenzae suis* and swine influenza virus in the pig can be reproduced by the inoculation of these agents on the choriocallantoic membrane of 9- to 10-day-old chick embryos. "Two strains of human influenza virus that were studied failed to substitute for the swine virus in the synergistic reaction. No loss of synergistic effect was noted when the swine influenza virus was put through 11 chick embryo passages. Recently isolated and old stock strains of *Hemophilus* were equally able to enhance the effect of the virus. Heat-killed cultures of *H. influenzae suis* can be substituted for the bacterial component of the reaction. Infection of the embryo with swine influenza virus predisposes to infection with *H. influenzae suis*. The

combination of *H. influenzae suis* and swine influenza virus causes a selective destruction of the embryo lungs not produced by the individual components. The pneumonia exhibits the essential features of the natural disease."

**Fowl-pox in domestic poultry**, E. M. DICKINSON (*Oregon Sta. Bul.* 411 (1942), pp. 27, figs. 6).—This practical account includes the results of field tests of baby chick vaccination, the details of which are given in a series of tabulated data. In the field trials on 28 poultry farms highly successful results were obtained. Emphasis is placed on the fact that only fowl pox vaccine and methods of application that have proved successful should be employed. Baby chick vaccination is not recommended to replace successful programs of vaccination of older chickens. It may be helpful on poultry farms where trouble is encountered when the birds are vaccinated at an older age. From 500 to 800 baby chicks can be vaccinated in an hour with a crew of two or three persons including the vaccinator. They are usually vaccinated when moved from the brooder house to the range (8-12 weeks of age) or at about a month before egg production is expected (3.5-4.5 mo. of age). Turkeys are usually vaccinated when they are moved from the brooder to range at about 8 to 12 weeks of age. Turkeys to be kept for breeders should be revaccinated.

**Experiments with greenmilk in chicken leukemia**, E. L. STUBBS and R. O. BUTZ (*Poultry Sci.*, 22 (1943), No. 1, pp. 49-52).—Greenmilk, which is a commercial product containing a combination of succulent cereal grasses and buttermilk (vitamins, proteins, and minerals) which is reputed when used as a supplement to grain and concentrates to be useful in conditions leading to anemia, was tested in transmissible chicken leukemia. Five experiments including 54 chickens were used in greenmilk feeding and injected with transmissible leukemia. Thirty-eight of the chickens developed typical leukemia while 16 did not. Since this is about the usual number of takes in routine transfers of leukemia, the greenmilk had no effect in prevention or cure.

**Serological studies on the avian leukosis complex.**—**Preliminary report on complement fixation**, M. POLLARD, W. J. HALL, and A. EICHORN (*Poultry Sci.*, 22 (1943), No. 1, pp. 20-24).—The anticomplementary character of chicken serum led to an investigation in which it was found that the whole blood and tissues of strain A leucotic chicks, chick embryos, and turkey embryos when inoculated into adult turkeys will induce specific complement-fixing bodies for strain A leucosis antigen. Strain A leucotic chick and chick embryo blood also induced similar antibodies in guinea fowls. "Strain B leucosis, morphologically similar to strain A leucosis and originating from a case of neurolymphomatosis, induced complement-fixing antibodies which were indistinguishable from those induced by strain A leucosis, and vice versa. While whole blood from a case of uncomplicated neurolymphomatosis induced complement-fixing bodies in turkeys for both strains A and B leucosis, the inoculations of whole blood and liver-spleen emulsions from cases of spontaneous visceral lymphomatosis into turkeys failed to induce such antibodies against either A or B antigen. Pending verification of these findings it appears that some serological relationship exists between strain A leucosis, strain B leucosis, and neurolymphomatosis distinct from that exhibited by spontaneous, nontransmissible visceral lymphomatosis. All of the complement-fixing antibodies which were induced in turkeys and guinea fowls by the leucosis agents exhibited a relative thermolability, the critical temperature being 56° C. after 6 min." A method of differentiating some of the manifestations of the avian leukosis complex by serological procedure is suggested.

**Directions for drawing blood samples for pullorum disease serum agglutination test**, E. M. DICKINSON (*Oregon Sta. Cir.* 144 (1942), pp. [4], fig. 1).—A description of the procedure to be followed in the drawing of blood samples for use in the serum agglutination test for pullorum disease.

**The practical application of the rapid whole blood agglutination test for pullorum disease,** R. F. GORDON (*Vet. Rec.*, 54 (1942), No. 48, pp. 495-497, figs. 3).

**The fowl tick (*Argas persicus*), a new vector of anaplasmosis,** D. E. HOWELL, G. W. STILES, and L. H. MOE. (Okla. Expt. Sta. coop. U. S. D. A.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 73-75).—In one of three experiments it was possible to transmit anaplasmosis of the cow by means of the fowl tick. Attempts to transmit the disease experimentally by means of the ear tick were unsuccessful.

**Sulfaguanidine as a prophylactic during the period of acquirement of resistance by chickens to cecal coccidiosis,** R. W. ALLEN and M. M. FARR. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 50-53).—In the experimental work reported sulfaguanidine administered in mash at a concentration of 0.5 percent for 3 days before and 14 days after young chickens were exposed to infection by means of inoculation and exposure to contaminated litter or by exposure to contaminated litter alone reduced markedly the mortality from cecal coccidiosis. Chickens so treated with sulfaguanidine and held on infective litter for 21 days after the cessation of treatment were fully as resistant to subsequent infection as the surviving untreated controls. The weight gains of chickens so treated and held on infective litter for 21 days after the cessation of treatment were not significantly different from those of surviving untreated controls.

**The disinfection of baby chick shipping boxes with sodium silicate solutions,** E. C. MCCULLOCH, S. A. FULLER, and L. M. KOGER. (Wash. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 4 (1943), No. 10, pp. 95-99).—Commercial water glass solutions (mixtures of  $\text{Na}_2\text{SiO}_3$  with more alkaline sodium silicates) containing from 8.9 percent  $\text{Na}_2\text{O}$  and 28.3 percent  $\text{SiO}_2$  to 14.5 percent  $\text{Na}_2\text{O}$  and 29 percent  $\text{SiO}_2$  were found to be effective germicides against gram-negative organisms. The phenol coefficient of these solutions is between 0.1 and 0.2, the more alkaline mixtures being more actively germicidal. Painting baby chick shipping boxes, between each reuse and after rough scraping to remove most of the accumulated feces, with equal parts of commercial water glass solution and water is recommended where the boxes must be reused because of present shortages. When carefully done this treatment will kill the more common poultry pathogens except *Mycobacterium tuberculosis*, does not weaken cardboard boxes, and is not injurious to baby chicks shipped in treated boxes.

**Perosis in turkey poults and the choline content of their diets,** R. J. EVANS, M. RHIAN, and C. I. DRAPER. (Wash. Expt. Sta.). (*Poultry Sci.*, 22 (1943), No. 1, pp. 88-93).—Experiments with perosis in turkey poults, an affection known to be due to a deficiency of either manganese or choline, are reported upon. A high incidence of perosis occurred in both of two choline diets prepared by modifying the commercial turkey-starting diet. This perosis was not completely prevented by adding sufficient choline to raise the level to 0.2 percent in the diet. The need for another factor or factors for the prevention of perosis when these diets are fed is indicated. There appeared to be a high negative correlation between the incidence of perosis in turkey poults and the choline content of their diets for all of the groups fed diets not containing added choline. A very high incidence of perosis occurred on a 32 percent protein diet with casein and pea meal furnishing the supplementary protein. This perosis was largely prevented by the addition of choline to the diet. Blood and bone phosphatase values appeared to be in no way related to the degree of perosis in the poults or to the choline content of the diets fed.

**Respiratory-nervous disorder in adult turkeys,** H. A. HOFFMAN (*Calif. Dept. Agr. Bul.*, 31 (1942), No. 3, pp. 130-133).—Report is made of the study of

a disease of adult turkeys characterized by respiratory and nervous symptoms, which was reproduced in young turkeys and chicks by using unfiltered and filtered inoculum. A few tests indicate the possibility that the virus is not filtrable through a Seitz filter. Six cockerels were immunized by repeated doses of formalized tissue vaccine followed by repeated doses of virus. Pooled serums from these cockerels in doses of 1, 2, and 3 cc., respectively, provided temporary protection against lethal doses of homologous virus. The same serums protected against the virus of respiratory nervous disorder of chickens. Attempts to immunize chicks through the use of mixtures of serums and virus failed. The reasons for these failures were not investigated. Preliminary trials on the use of tissue vaccines inactivated by formalin and chloroform were not encouraging. The development of a highly potent serum indicates the advisability of further investigations of this as an immunizing agent. Also, trials in the use of serum and virus as immunizing agents are indicated. Details of the inoculum trials are presented in table form.

## AGRICULTURAL ENGINEERING

**Agricultural engineers on the food front**, H. B. WALKER. (Univ. Calif.). (*Agr. Engin.*, 24 (1943) No. 1, pp. 5-7, 10, figs. 2).—This is a presidential address concerned largely with the viewpoint that while we have been building up the arsenal side of our war effort at an amazing rate, we have been quite indifferent to the true situation regarding our farm production units. "Agricultural surpluses from past years and a bountiful nature in 1942 have not helped to arouse public consciousness to the true situation. Yet a view of the food stocks on the shelves of our local grocery stores should be a reminder of the diminishing supplies of foods for local consumption." However, "regardless of the difficulties we may be called upon to face in our battle on the food front, we must keep on fighting, using our technical knowledge to the fullest in keeping farm machines rolling in the fields to produce every pound of food possible . . ."

**Agricultural engineering suggestions for 1943**, E. G. MCKIBBEN (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 223-229, figs. 3).—Since some definitely needed new equipment cannot be obtained, every effort should be made to keep all equipment in working order and arrangements attempted for increased exchange of equipment between farmers. The author holds that, in general, any new equipment or materials which will reduce labor or aid in production should be purchased if available. In discussing buildings, fences, the use of electricity, field equipment, tractors, land development, etc., he emphasizes primarily time and labor saving and care in conserving equipment now in hand. A final section on conservation of life, products, and equipment stresses fire prevention and precautions against personal injury.

**[Agricultural engineering investigations of the Bureau of Agricultural Chemistry and Engineering]** (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin. Rpt.*, 1942, pp. 36-43).—The main topics for which data are reported are farm structures for storing crops, equipment for fighting plant pests, machinery for conserving fertilizer, machines to increase production or reduce cost of crops, special equipment for mulch culture and for low-income farmers, ginning cotton for best fiber quality, making cotton bales better at gins, flax-pulling and flax-processing machines, equipment for cooling eggs on farms, and hemp-processing machines.

**Western ground waters and food production**, J. A. BIRD (*U. S. Dept. Agr., Misc. Pub.* 504 (1942), pp. 40, figs. 22).—This is a condensed, more or less popularized statement of the nature, use, control, and conservation of ground water, with reference especially to areas of arid or semiarid surface. The main captions

under which the present treatment is arranged are where water rules, ground water—what it is, ground-water law, ground water—how it has been used, and planning for better water-land use.

**Surface water supply of the United States, 1939.—Part 3, Ohio River Basin, C. G. PAULSEN ET AL.** (*U. S. Geol. Survey, Water-Supply Paper 873 (1941), pp. XI+578, pl. 1*).—This paper records measurements of stream flow for the year ended September 30, 1939.

**Water supply of the Dakota sandstone in the Ellendale-Jamestown area, North Dakota, with reference to changes between 1923 and 1938, L. K. WENZEL and H. H. SAND** (*U. S. Geol. Survey, Water-Supply Paper 889-A (1942), pp. IV+81, pls. 3, figs. 3*).—The Dakota sandstone underlies most of North Dakota and South Dakota and considerable parts of nearby States. Where the topography is favorable, as in the Ellendale-Jamestown area in southeastern North Dakota, wells that tap the sandstone flow at the surface. The history of the development of the use of artesian wells in this area is traced from the time of the first well drilled (1886) through a period of excessive draft and the introduction of control measures (restriction to beneficial use), and to present conditions in the area. The quality of the water is described as poor, the dissolved solids amounting to 2,200 p. p. m. or more, with a fluoride content sufficient to cause mottling of the teeth. Present use appears to be approaching a balance between the withdrawal of water from the basin and the perennial recharge to it.

**Ground-water resources of the Willamette Valley, Oregon, A. M. PIPER.** (*Coop. Oreg. Expt. Sta.*). (*U. S. Geol. Survey, Water-Supply Paper 890 (1942), pp. V+194, pls. 10, figs. 3*).—The northern segment of the main plain has both unconfined water, semiperched at shallow depth beneath the "prairies," and confined water in extensive pervious zones, which in one typical well are about 70, 120, and 220 ft. beneath the surface. The semiperched water bodies will not sustain large withdrawals for irrigation. The confined water, presumably derived from a catchment area to the south and east, supplies wells that yield as much as 1,000 gal. a minute, with maximum pumping lifts of about 60 ft. It would probably supply several or many times its present draft. The southern segment contains many lentils and tongues of clean gravel and sand that supply as much as 500 gal. of water a minute to wells of shallow or moderate depth and of the simplest construction. Efficiently constructed wells penetrating the full thickness of the deposit very probably would yield much more copiously. Beneath the flood plains of the Willamette River and its principal tributaries, the younger alluvium is highly pervious at most places. It supplies as much as 1,000 gal. of water a minute to wells of simple construction and would, doubtless, sustain a much larger aggregate withdrawal.

In chemical character the water from all the unconsolidated deposits of the Willamette Valley is satisfactory for most uses. Some waters contain an excessive amount of iron. At many places the bedrocks, especially the sedimentary rocks of marine origin, yield water of excessive hardness or so concentrated in dissolved mineral constituents as to be unsatisfactory for ordinary uses.

**A method for determining the velocity of runoff water, A. W. COOPER and J. H. NEAL** (*Ala. Expt. Sta. and U. S. D. A.*). (*Agr. Engin., 23 (1942), No. 12, pp. 385-387, 389, figs. 6*).—Equipment now available, including two 15- by 50-ft. tilting plats, artificial rainfall set-up, etc., is described in some detail, together with the calibration of rainfall apparatus by a method developed by D. A. Parsons of the Soil Conservation Service and the method of determining velocity. Data enough to permit drawing definite conclusions have not been obtained, but the results show probable trends. In general, velocity of sheet or overland flow of water increased with degree and with length of slope. After rills had formed

in the Decatur clay loam, however, the velocity of flow became erratic and increased or decreased, depending on whether the water was flowing in rills or had spread out. No attempt has yet been made to correlate velocity of flow of the run-off water with the soil losses, because the soil losses decreased with length of rainfall application.

**The use of current meters in measuring pipe discharges, C. ROHWER.** (Coop. U. S. D. A.). (*Colorado Sta. Tech. Bul.* 29 (1942), pp. 40, figs. 18).—For current meter pipe discharge measurement the area-velocity product was too large, probably because the current meter did not measure the low velocities near the walls of the pipe, but the correction factor was constant under standard conditions for each size of pipe unless the velocity was sufficient to affect the registration of the current meter. The velocity became too great for accurate measurement at about 10 ft. per second in 12-in. pipe and at about 9 ft. per second in small pipes. The general law showing the relation between velocity of the water as measured by the meter and discharge for all sizes of pipe is given as  $Q = (419A - 5)V$  in terms of area of the pipe and  $Q = 1.815D^2 V$  in terms of the diameter of the pipe. The discharges computed by the formula  $Q = (419A - 5)V$  were, in general, slightly closer to the actual discharges. A comparison of the observed and computed discharges for all tests regardless of conditions, except those with spiral flow, showed that 79 percent of the computed results were not more than 3 percent in error and 92 percent were not more than 5 percent in error. Of two equally satisfactory methods of integrating the flow with the current meter, the combination of horizontal, vertical, and circular integration is recommended because the discharge formulas are based on measurements by this method. Both Ott and Hoff rubber-propeller meters of the type tested were equally satisfactory in measuring pipe discharges.

A statistical analysis of the effect of length of pipe on the accuracy of the current meter measurements showed that the differences were not significant. Outlet pipes at least 6 ft. long are recommended, however, because an obstruction in the pipe or other disturbing factor has less influence in long pipes. Adding an elbow at the pipe inlet to simulate the condition found in pump discharge pipes did not affect the accuracy of registration of the current meters for pipe lengths greater than six diameters. A right-angle inlet in a horizontal plane materially affected the registration of the meter if the outlet pipe was 2.5 ft. long, but had little effect if the outlet pipe was 6 ft. long. Measurements of the Fort Collins laboratory pump discharge with the Hoff current meter when the discharge pipe was 6 ft. long checked the Venturi meter measurements if the gate valve was not more than half closed. Measurements of spiral flow with a current meter were found to be unsatisfactory. Straightener vanes in the pipe were effective in straightening the lines of flow in the pipe and in reducing the error in the current meter measurements to less than 3 percent. A slight slope in the discharge pipe did not affect the accuracy of the current meter measurements; neither did such roughness as would be caused by pitting due to rusting.

**Movement of soil during tillage operations, S. J. MECH and G. R. FREE.** ([N. Y.] Cornell Expt. Sta. and U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 12, pp. 379-382, figs. 6).—Movement of soil by tillage implements moving up or down the slope was measured in boxes having removable ends to permit entrance of the implement at operating depth. For the up or down slope movement in tillage across the slope, soil boxes 4 ft. square and filled with soil to about 6 in. in depth were supported at one side by a chain hoist for slope adjustment and at the other by a platform scale, permitting up or down slope soil movement to be calculated in foot-pounds per foot of implement travel by the moment principle from the change in reading of the scale.

Soil movement downhill during harrowing and cultivating operations increased as the slope was increased. A duckfoot cultivator shovel operated on the contour produced soil movement downhill approximately equal to that when it was operated up and downhill. A reversible cultivator shovel operated on the contour produced greater soil movement downhill than when it was operated up and downhill. In contour plowing under field conditions there was very little actual difference in the amount of the soil movement on different slopes. Soil movement uphill on a slope of 16.9 percent when contour plowing and throwing the furrows uphill was 51 percent less than soil movement downhill when throwing the furrows downhill, but the width of cut was 20 percent less. No difficulty in turning furrows uphill when contour plowing a 16.9-percent slope was experienced. However, the angle of the furrow slices indicated that the upper limit of slope for turning furrows uphill was nearly reached. On a 20- by 100-ft. plat, turning the furrows downhill in contour plowing would produce soil movement 38 times as great as that represented by an erosion soil loss of 1 ton per acre from the plat when the unmeasured movement on the plat during the latter process is not considered. The bottom furrow on this plat, if turned downhill and off the plat into the catchment equipment, would weigh 892 lb., amounting nearly to 10 times the weight of soil equivalent to an erosion loss of 1 ton per acre. Turning furrows uphill during contour plowing was the only feasible form of operation that moved soil uphill to compensate to some extent for the unavoidable downhill movement during cultivating, harrowing, and erosion processes.

**Lumber requirements on the farm, F. J. HALLAUER** (*U. S. Dept. Agr., Forest Serv., 1942, pp. III+75, figs. 26*).—This publication is one of a series of progress reports on a Nation-wide Forest Service survey authorized by the McSweeney-McNary Forest Research Act of May 22, 1928. It analyzes and discusses the estimated farm lumber requirements for repairs and replacements of buildings, for miscellaneous purposes, and for new construction. The future need is discussed in sections on appraising the backlog of deferred farm building improvements, and higher building standards would require more lumber.

**Report of the Administrator of the Rural Electrification Administration, 1942, H. SLATTERY** (*U. S. Dept. Agr., Rural Electrification Admin. Rpt., 1942, pp. 19*).—This report takes up operations during fiscal year 1942, war research, rural electrification and the law, and the fiscal status of R. E. A. borrowers.

**Production rating of farmers under wartime conditions, F. J. ZINK** (*Agr. Engin., 24 (1943), No. 1, pp. 19-21*).—The author notes the need for a scale or measure of some sort, by means of which the farmer himself, and others, may state efficiency in definite terms, citing as an example of such a score sheet the New Hampshire extension economist's "yardstick for farm and labor efficiency," in which one work unit is equal to a 10-hr. day and a full-time work year would be from 275 to 325 work units. This New Hampshire score card offers the farmer a means of self-checking the crops and livestock produced, multiplying the numbers of each by a conversion factor to determine the total units of output in relation to the work units of input. The operator calculates the total work units required for his operation, which merely shows whether "a farm really needs more workers than it now has on the job," also, it will show if "a farm has more manpower than it needs." The author also includes and briefly discusses a farm production rating form suggested for use by selection boards as applying to individual farmers for 1-yr. periods.

**Wartime allocation of farm machines, A. W. TURNER** (*Agr. Engin., 24 (1943), No. 1, pp. 22-24*).—A farm production rating form basically similar to those proposed in the preceding article is suggested for use in connection with applications for machines. The form is designed to provide a complete production picture.

Its structure is briefly discussed, and its use is illustrated. The paper is a report of the American Society of Agricultural Engineers Committee on Wartime Allocation of Farm Machines.

**Nation-wide farm equipment conservation program, S. P. LYLE.** (U. S. D. A.). (*Agr. Engin.*, 24 (1943), No. 1, pp. 13-14, 16).—This is a general résumé of the current labor machinery situation created by induction of farm workers into the armed forces, absorption of many others by war industries, and the reduction of new machinery production to 20 percent of the 1940-41 average. An uneven distribution of productiveness among farms, of which one-third produce 84 percent of the total, one-third turn out 13 percent, and the remaining third contribute only 3 percent of the marketed surplus, is another phase of the agricultural war production problem here outlined. Some increase in production on the small, low-production farms may be expected, but most of the load of the required increase must rest upon the 2,000,000 farms now producing 84 percent, and some of their necessary increase in experienced personnel must come from the smaller, less efficient farms.

With reference to the farm machinery problem it is noted that a vigorous machinery conservation program is required, but a number of favorable factors influence the situation, the following being among those enumerated: The inventory of machines on farms is probably greater than at any previous year; there are more tractors on farms than at any previous time; a very large percentage of the machines on farms has been in use less than 3 yr.; a large percentage of farm machines have been kept in good condition in 1942; excellent repair shop and garage facilities are available throughout the country for servicing tractors and doing welding and other difficult repairs; most repair shops can deal effectively with the repair jobs during winter if orders are placed promptly and the work is spread over the dormant season; at the farm level of analysis each farm is fairly well equipped for most operations in its schedule of production, and most farm managers can make certain that their machines are ready for the 1943 work; etc. Other favorable possibilities noted are that of the sharing of labor and equipment resources, custom work, and the development of home-made equipment. The probability of an adjustment of farm product prices and wages is also included.

**The rationing of farm machinery, L. L. NEEDLER.** (U. S. D. A.) (*Agr. Engin.*, 24 (1943), No. 1, pp. 17-18).—The author, director of the U. S. D. A. Division of War Board Services, briefly sets forth progress thus far made in the planning of the distribution of the available supply, "much less than was purchased during the depths of the depression when manpower was abundant and the price of farm machinery was high in relation to the value of farm commodities." State quotas on nearly all the rationed items have been established after taking into account such factors as the historical purchase and use of equipment; to what extent the planting, cultivating, and harvesting of farm crops has been mechanized in the various States; the food goals, with special emphasis on the war crops; climatic conditions; recent trends of use; availability of farm labor; and other factors. The State war boards have been asked to break their State quotas down into county quotas. Some other details of the tentative plan of distribution are outlined. Custom operation is indicated as an important factor in the accomplishment of increased production with lowered equipment supply.

**Rental rates for farm machinery, C. B. RICHEY ET AL.** (*Agr. Engin.*, 24 (1943), No. 1, pp. 15-16).—The essential finding of this committee report is that a rental schedule should meet the following requirements: (1) Provide an incentive to the average farmer to rent out his machines when they have extra capacity which is needed in the neighborhood. To this end a reasonable margin of profit above the total cost of service at average usage must be provided. (2) Be concise,

easily calculated, leave little room for disputes, and be easily understood. (3) Compensate for differences in delivered prices in different sections of the country. (4) Compensate for differences in cost of use due to differences in amount of annual use in different areas. (5) Compensate for differences in rates of wear due to variations in operating conditions. (6) Be adapted to use by farm machinery dealers operating a rental business as well as by farmers.

The method used in arriving at such a schedule and a tabulation of the committee's results in terms of basic rental rates per hour per \$100 of original value, both for the first 5 hr. and for further periods, accompany the report, together with a table of basic assumptions and cost estimates.

**Farm machinery in Britain's food production effort, J. A. S. WATSON** (*Agr. Engin.*, 24 (1943), No. 1, pp. 11-12).—The author presents a brief outline of the British system of intensified agricultural production, outstanding features of which are the county war agricultural executive committees and the special sub-committees for the handling of machinery problems, the annual estimation of new machinery requirements, and the management of the machinery pool, the last-named consisting of equipment owned by government and under the complete control of the committee. Of this government-owned equipment he notes that in a typical county containing some 200,000 acres the pool might contain 100 tractors with appropriate numbers of plows, cultivators, disks, seeders, binders, separators, etc. The number of government-owned tractors is about 7 percent of the total in the country, but in counties of small farms, or of farms with small areas of cultivated crops (i. e., in mainly pastoral districts), the size of the pool will be proportionately large. By contrast, in counties of large farms which can provide full employment for one or more tractors the bulk of the necessary equipment will be owned by farmers themselves and the county pool will be relatively small. In a majority of cases the whole of the pool equipment is actually operated by the committee's own employees and carries out custom work for farmers at fixed rates. Obtainment of a new machine by an individual purchaser is by application to the county committee, of which the "machinery officer" ascertains either (1) that there is full work for the implement in question on the applicant's own farm or (2) that the applicant is willing to register as a contractor, and that there is full work for the implement on his own farm and those of his neighbors, and gives the application an "A" priority rating; or is not satisfied as to these conditions and rates the application "B" or "C". It is, however, "very rare for a B priority to produce any response." Some control measures applied in the farm machinery industries to insure concentration of effort upon the types of machines most needed at the moment are also briefly noted.

**The effect of the jacket water temperature on crankcase dilution and fuel economy of a tractor engine, A. H. THOMPSON.** (*Univ. Ark.*). (*Agr. Engin.*, 23 (1942), No. 12, pp. 383-384, 389, figs. 5).—By arranging two radiators in series and providing radiator curtains, temperatures at the outlet from the engine jacket to the first radiator could be controlled within 2° F. at temperatures as low as 100°. Tests were run with 73 octane gasoline burned with 5.9:1 compression ratio and cold manifold, with 33.5 octane distillate burned with 4.75:1 compression ratio and hot distillate manifold, and 73 octane gasoline burned with 4.75:1 compression ratio and distillate manifold with cold setting. An S. A. E. No. 30 oil was used. Tests for the determination of crankcase dilution were run 5 hr. with a load of 18 hp. and an engine speed of 1,700 r. p. m., and the jacket water temperature was varied from 100° to 200°.

When distillate was burned, the lubricating oil was diluted as much as 14.4 percent in 5 hr. at 100° jacket water temperature. At 200° the lubricating oil was diluted only 5.6 percent in 5 hr. The rate of dilution was increased 1.9 times

by changing the jacket water temperature from 200° to 175°. When gasoline was burned, dilution of the lubricating oil by the fuel was considerably less than when distillate was burned. However, gasoline dilution in 5 hr. was doubled when the jacket water temperature was changed from 200° to 100°. There was less dilution when gasoline was burned with a 5.90:1 compression ratio and cold manifold than when it was burned with a 4.75:1 compression ratio and distillate manifold. The oil dilution was 40 percent more at the end of 5 hr. when distillate was burned with the jacket water temperature at 200° than when gasoline was burned with the jacket water temperature at 100°.

In the fuel consumption tests it was found that when distillate was burned the engine detonated rather severely when a load of more than 18 hp. was applied. No detonation occurred at any time when gasoline was burned. In almost every test decreasing the jacket water temperature resulted in increasing the specific fuel consumption. The jacket water temperature was varied from 100° to 200° in 25° steps, but the increase in fuel consumption was small for each temperature change and there was no consistency in the change in fuel consumption for each 25°-temperature step made. When distillate was burned, a change from 200° to 100° in the jacket water temperature increased the specific fuel consumption only 6.6 percent when the engine was developing 14.5 hp., but when the engine was developing 3.6 hp. the same change in jacket water temperature increased the specific fuel consumption 12 percent. When gasoline was burned with a 4.75:1 compression ratio there was a considerable increase in the specific fuel consumption when the jacket temperature was changed from 200° to 100° for all the different engine loads. When gasoline was burned with 5.90:1 compression ratio a change in jacket temperature seemed to have a greater effect on the specific fuel consumption as the load on the engine decreased. At maximum load changing the jacket water temperature had practically no effect on the specific fuel consumption, but when the load was decreased to about 6 hp. the specific fuel consumption was increased 10 percent when the jacket water temperature was decreased from 200° to 100°.

**How to make a thresher for castor beans, J. B. KELLEY** (*Kentucky Sta. Cir. 53 (1942), pp. 4, figs. 2*).—In the machine here described the pods pass between a revolving wooden cylinder (11.5 in. in diameter, 18 in. long, and covered with corrugated rubber floor matting, of which the corrugations are laid parallel with the axis of the cylinder) and a floor matting apron of which one end is tacked to the top edge of an adjustable board in the bottom of the hopper and in front of the cylinder. The other end of the apron passes over a 3- by 18-in. wooden roller and extends down into a removable drawer. The apron should be so cut that the corrugations will be at a slight angle with those on the cylinder. The wooden roller is mounted off center and is provided with a crank to turn it to adjust the space between the cylinder and the apron. At each end of the roller the bearing blocks are mounted between guides with one end of each resting against a ¾- by 3-in. compression spring. A ¼ hp. electric motor is used. An average rate of 183 lb. of cleaned beans per hour was obtained.

**Develop a farm-sized rice drier** (*Arkansas Sta. Bul. 428 (1942), pp. 17-18*).—Rice must be cut at a moisture content not much below 20 percent but cannot be stored safely at more than a 14-percent moisture content. E. L. Barger, K. Engler, and A. H. Thompson have built an experimental drier of a continuous-flow, tower type, of which a brief, partial description, without drawings, is here given. Air, heated by an oil-burning, domestic-type furnace, is delivered to the drier chamber by an electrically driven blower.

**Baling straw left by combine, A. L. YOUNG.** (Univ. Ill. coop. U. S. D. A. et al.) (*Agr. Engin., 23 (1942), No. 12, pp. 377-378, 389, figs. 2*).—Tests to com-

pare three methods of combining and saving the straw were made. (1) The 6-ft. combine was operated to cut with a low (5-in.) stubble, the straw was left in a windrow, and this windrow was baled with the pick-up baler. (2) The combining was kept as nearly as possible as in (1), but an attachment whereby two windrows of straw were thrown together was used. The baler had to travel much more slowly while picking up this double windrow, and occasionally the tractor pulling the baler had to be stopped momentarily until the pick-up baler and feed mechanism cleared. (3) The combine was operated to leave a stubble of normal height (from 11 to 14 in.), and the straw was left in a single windrow. The tractor pulling the baler (a tractor larger than that used in the other tests) was equipped with an 8-ft. mower having a curved bar windrowing attachment. The stubble left by the combine was mowed, and it, as well as the straw left by the combine, was delivered by the windrower to the pick-up of the baler. The total loss of grain was less when cutting with a 5-in. stubble than when the stubble was from 11 to 14 in. In this case the reduction of the cutter bar loss, due to lower cutting, more than offset the slight increase in the loss in the straw and chaff caused by the greater amount of straw. This would not always be so, however. If operating to secure a low stubble were to cause much green material to pass through the combine and to result in high grain losses and high moisture in the threshed grain, it would probably be more satisfactory to cut a high stubble, and mow the stubble as was done in test (3). The cost per acre should be slightly less for test (3) than for the other two because of the higher rate of travel and increased acres per hour harvested. It is considered doubtful if the saving in cost of combining when cutting the grain high as compared with cutting low would offset much of the increase in cost of saving the straw. Combining with a high stubble could not be justified when, as here, the total grain losses were more than when cutting low.

**Plans for saving and straightening bale ties**, F. E. PRICE and D. E. KIRK (*Oregon Sta. Cir. 145 (1942)*, pp. 8, figs. 3).—Detailed and fully dimensioned working drawings for an effective but simple and inexpensive bale tie straightener are reproduced in this circular and are accompanied by a bill of materials and brief discussion of the construction and operation of the device. The estimated cost of all required materials is \$1.

**Sorting chutes, panels, hay self-feeders will make lamb feedlot operations easier**, A. L. ESPIN (*Colo. Farm Bul. [Colorado Sta.], 5 (1943), No. 1, pp. 6-7, figs. 3*).—The plan of a chute, a dimensioned elevation drawing of a self-feeder for ground hay, and a drawing of a light fence panel for sheep feed lots, with brief descriptive legends, constitute the entire presentation of this topic.

**Self-feeder, movable automatic waterer suggested as labor savers in hog growing**, R. WILKES and H. C. DICKEY (*Colo. Farm Bul. [Colorado Sta.], 5 (1943), No. 1, p. 11, fig. 1*).—A tight barrel with both heads in good condition is placed on a watertight platform surrounded by a 4-in. ledge, the whole being mounted on two 4- by 6-in. runners 4 ft. long. The outlet at the bottom of the barrel is put at a height such as will place the top of the hole 1 in. below the top of the ledge. The barrel is filled through a stoppered opening at the top. The self-feeder here mentioned is not described, but its value and use are briefly discussed.

**A program for postwar farm building**, R. CROW (*Agr. Engin., 23 (1942), No. 12, pp. 373-376, figs. 2*).—"However important such a program would have been in the past, its successful prosecution during the immediate post-war period will be doubly so as a post-war economic measure." The raising of the farmer's efficiency and operational scope, with concomitant raising of living standard

and purchasing power, and the absorption of an appreciable part of the labor and material to be thrown on the market with the ending of war work are considered possible aids against the post-war depression anticipated by many economists.

**Farm structures prefabrication, J. D. LONG** (*Agr. Engin.*, 24 (1943), No. 1, pp. 8, 10).—The author defines precutting (of individual pieces to fit directly into the structure), prefabrication (of panels and structural parts), and pre-assembly (full completion of small units to be shipped as a whole), pointing out as advantages common to all three systems that they encourage better selection of materials for specific uses in the building; permit use of accurate, labor-saving shop equipment; permit shop fabrication under more comfortable and more effective working conditions than are usual in conventional construction; stop haulage of unnecessary and waste materials; by displays maintained by fabricator or his salesman permit the farmer to select the structure which most exactly meets his requirements, wishes, or pocketbook; permit the design to be controlled by the fabricator, presumably with qualified reasons, rather than left to the whim or tradition of the country carpenter; and allow economies in selection and utilization of materials and in labor which result in lowered costs to the purchaser, or superior quality at the same cost.

The author holds that prefabrication of farm structures has permanently established itself, and that, although it will not supplant conventional construction, it will prove "a worthy competitor" in some items of farm construction because it renders a distinct service to the farmer.

**Emergency storage for soybeans, J. C. WOOLEY** (*Missouri Sta. Cir.* 240 (1942), pp. 4).—Temporary structures for the storage of soybeans are not recommended. Conversion of cornerbills and already existing bins is preferred to the putting up of temporary buildings. Because of the weight (48 lb. per cubic foot) and the mobility of the stored beans the side wall pressure is such that cribs should not be more than half filled. One-fourth-inch mesh wire cloth nailed inside the studding is recommended to provide air circulation. In buildings made for the purpose, side wall strength should be equivalent to that of 2- by 6-in. studding spaced 16 in. on center for storage of beans to a depth of 8 ft. Suitable joist sizes and spacing for various spans are also specified.

Beans having a moisture content of from 10 to 12 percent could be handled as are other grains, but a moisture content above 13 percent is considered not safe in storage. Arrangements necessary for obtaining materials and loans for storage construction are briefly discussed.

## AGRICULTURAL ECONOMICS

**Report of the Chief of the Bureau of Agricultural Economics, 1942, H. R. TOLLEY** (*U. S. Dept. Agr., Bur. Agr. Econ. Rpt.*, 1942, pp. 15).—The work of the Bureau during the year is set forth, including work on production goals in 1942 and aid in establishing 1943 production goals. A discussion follows of critical commodities in the war effort, program analysis, problems of technology, production costs and returns, low-income farming, basic data for price-control measures, financial problems in wartime, production estimates and reports, participation of farmers in group discussions, keeping track of population and labor movements, and land values through periodic surveys.

**Farming efficiently under war conditions, M. J. PETERSON** (*South Carolina Sta. Cir.* 63 (1942), pp. 8, fig. 1).—Items discussed include labor efficiency and

income and ways of improving them, which consist of increasing the size of the farm business, better distribution and management of labor, efficient use of machinery, and changes in the farm lay-out and building arrangement. It is suggested also that debts be paid, new indebtedness avoided, and savings made through the purchase of war bonds.

**Forecast of changes in California agricultural production in 1943 (as of January 5, 1943),** R. L. ADAMS (*California Sta.*, [1943], pp. 32).—This report on forecasted changes in acreages of California crops, numbers of livestock, and production outlook of both crops and livestock is based largely on 149 replies to questionnaires sent to 194 persons on December 1, 1942. Opinions were obtained for 52 crop and 10 livestock enterprises.

**Factors affecting farming returns in Jackson County, Florida,** M. E. BRUNK (*Florida Sta. Bul.* 377 (1942), pp. 36, figs. 7).—The agricultural development of the county—population growth, number and size of farms, crop and livestock trends, number of farm conveniences, etc.—is described. The analyses of factors affecting farming returns are based chiefly on a farm management study of 490 farms in 1925, supplemented by data obtained in 1941. Some data from less extensive farm management studies in 1928, 1934, and 1935 were also used. The effects on returns of soils (by J. R. Henderson), location of markets, size of business, labor efficiency, crop yields, tenure, education of operators, prices, and cropping practices are analyzed and discussed. Real estate taxation in 1941 is discussed briefly.

**Farm adjustment opportunities in Greene County, Georgia,** M. C. CONNER, W. E. HENDRIX, C. R. SAYRE, and W. T. FULLILOVE. (Coop. U. S. D. A.). (*Georgia Sta. Bul.* 221 (1942), pp. 74, figs. 8).—"Using price and cost relationships at 1936-39 levels the bulletin outlines adjustment opportunities for representative farms for each major size-type group within the present land base available on such farms. In addition, it outlines family-sized units and the number of families which the county could support on such units if the restabilization and development of agriculture in the post-war time is to be on a family-sized farm basis." Data on land use, yields, and tenure were tabulated from 1938 A. A. A. work sheets for 1,026 operating units. Supplementary information regarding livestock was obtained through questionnaires. Visits were made to 185 farms selected at random to ascertain farm prices, costs, labor requirements, etc., and to 49 additional farms to obtain information on enterprises and practices found infrequently in the area. Detailed studies were made of representative farm organizations in each size-type group of farms. The area, its historical development, the present agriculture, etc., are described, as are also the production practices for crops, pastures, livestock, and woodlands. The organization and incomes of representative small, medium-sized, and large farms of different types and the reorganization of such farms with present acreages and to secure family-sized units are analyzed and discussed.

As regards adjustments with present land acreages, the authors state: "These adjustments, if made on all farms in the county, would result in about four times as large an acreage of non-soil-depleting crops and approximately twice as great an acreage of small grains. Such adjustments would contribute much toward the conservation of the county's land resources. At the same time they would provide an increase of \$118,000 in the total farm income. Such increase would make a substantial addition to the county's capacity for building and maintaining roads, schools, churches, and other service institutions. The welfare of both farm and nonfarm families would be benefited. With these adjustments enough surplus labor still remains during slack farming seasons

to perform 562,000 days of work, of which 284,000 days are suitable for field work. Utilization of such surplus labor in productive work is a major rural problem in the area."

As to adjustments to secure family-sized farms, they state: "Adjustments to secure a family-sized unit for all farm families in the county would increase the acreage of cropland from about 46,000 acres to 84,000 acres. This could be accomplished if most of the Class III land were brought into production. Total cash receipts would be increased from \$501,000 to \$953,000 and farm income increased from \$220,000 to \$461,000. This income, both because of the amount and the desirable distribution, would pay for many essentials now lacking for the well-being of farm people."

**The management of farms in the limestone area of south-central Indiana, with special reference to the provision and utilization of pasture,** F. V. SMITH (*Indiana Sta. Bul. 473 (1942), pp. 51, figs. 6*).—Farm management and land utilization studies in the limestone area have shown some of the more important farm management problems to be: (1) A large percentage of the land in the area is not adapted for efficient crop production; (2) a large percentage of the farms in the area are too small for economical units of the predominating types of farming followed; (3) the use of land not well adapted to the production of rotation crops coupled with intensive farming, made necessary because the farm units were too small, have caused a marked reduction in soil productivity, and a considerable acreage has been abandoned because of the loss of fertility and damage from erosion; (4) since a large percentage of the land in the area is better adapted to the production of grasses and legumes than to the production of corn and small grain, how does pasture fit into the more important types of farm organization in the area? (5) what pasture management practices, with reference to the establishment, maintenance, and utilization of pastures are practical?

This bulletin makes a detailed analysis of a successfully operated farm representative of each of five types of organization in the area. Special attention is given to the place of pasture on these farms. The analysis includes the management of a large, extensively operated farm, a large diversified farm, a 200-acre dairy-hog farm, a 160-acre diversified farm, and an 80-acre diversified farm. Soil types and land use, crop yields, livestock enterprises and pasture utilization, pasture costs, and pasture management practices are discussed, and tables are included giving a financial summary and the farm business factors by years 1932-36, inclusive. The procedure used in calculating pasture costs is briefly described.

**Sizes and types of farms in relation to farm income in Quay County, New Mexico.** P. M. McMANS and P. W. COCKERILL. (Coop. U. S. D. A.). (*New Mexico Sta. Bul. 296 (1942), pp. 41, figs. 5*).—The gradual adjustment in size of farm and ranch units in Quay County since early settlement is noted. The number of units has decreased, and the size has increased. The need is pointed out for a further reduction in the number of substandard farms and ranches in the interest of rural welfare and conservation of resources. Income is increased by the production of livestock in addition to row crops. Conservative grazing is recommended to obviate the hazards of forced sales of livestock in drought years.

**Size of farm units as affected by the farming of additional land,** R. C. HEADINGTON and J. I. FALCONER. (Coop. U. S. D. A. and Ohio State Univ.) (*Ohio Sta. Bul. 637 (1942), pp. [1]+19, figs. 4*).—A study of 300 farming units in 3 sample areas of Darke County for the period 1937-40 showed that the average farm unit had increased in size from 89.5 to 90.5 acres, while the number

of owners who were renting some additional land to farm increased 30 percent and the number of tenants who were doing likewise increased 44 percent. About 75 percent of the additional land was obtained by renting. The reasons given by 63 operators for renting additional land reflected the desire for more feed, pasture, cropland, and/or income. Ninety-three percent of the additional tracts were rented on a crop-share basis, 6 percent for cash, and the remainder by a combination of both methods.

**Milk and egg production on farms, D. DICKINS** (*Miss. Farm Res. [Mississippi Sta.]*, 6 (1943), No. 1, p. 8).—Data on milk and egg production of 832 farms in two counties in Mississippi showed that the production per family was less for 2-, 3-, and 4-family farms than for 1-family farms where an average of 883 gal. of milk and 199 doz. eggs per family were produced. It is recommended that milk and egg production per family be increased, especially on the large-scale farms.

**Economic aspects of onion production in northern Indiana, L. ROBERTSON** (*Indiana Sta. Bul.* 475 (1942), pp. 23, figs. 11).—Information regarding the methods used in producing onions and the costs and returns obtained were gathered from 35 to 65 representative farmers in the years 1934, 1935, 1938, and 1941. The production practices, labor requirements, seasonal distribution of labor, power requirements, costs and returns, and variations between years are described and discussed. The effects of prices, yields, and different production methods on returns are analyzed and discussed. Onion rental methods and cost methods used in the State are described.

**The economics of the poultry enterprise on Kansas farms, R. W. HOECKER** (*Kansas Sta. Bul.* 308 (1942), pp. 48, figs. 19).—In 1940, poultry on 87 percent of Kansas farms accounted for about 8 percent of the farm cash income. In 1941, receipts from 38 general-purpose flocks averaged \$4.17 per hen, while receipts from 33 egg-breed enterprises averaged \$3.98 per hen. Total operating expenses of the general-purpose flocks were \$2.35 per hen and in the egg flocks \$2.22 per hen. To care for 100 hens took an average of 1 hr. 22 min. a day, 150 hr. being spent in rearing replacements and 348 hr. on the laying flock. The average income from general-purpose breeds was \$1.83 per bird, while that from egg-breed flocks was \$1.56. More universal buying and selling of eggs and poultry on a graded basis is recommended as helpful in obtaining higher returns to Kansas farmers.

**Trends in Kentucky agriculture, 1929-1940, D. L. MACFARLANE and M. M. THARP** (*Kentucky Sta. Bul.* 429 (1942), pp. 51, figs. 10).—"To trace the trends in Kentucky agriculture from 1929 to 1940, particularly with respect to use of land, numbers and kinds of livestock, incomes, and attitudes toward and participation in the program of the Agricultural Adjustment Administration, data were gathered from census reports, from the State and Federal crop and livestock reporting service, from the Agricultural Adjustment Administration, and direct from some 500 farmers in 4 representative areas of the State." The trends in land use and number of livestock in the State as a whole and in each of the 8 type-of-farming areas and the changes in cash farm income during the period are discussed. Special analyses are made of the trends in land use and in farm organizations in Graves, Christian (southern part), Trimble, and Casey (upland and ridge portions) Counties. In a section on the trends in Kentucky agriculture in relation to the A. A. A. program, the aspects of farm practice, organization, and income on which the programs bear most directly are analyzed. These include "(1) measures of conservation achieved, (2) cover crop practices, (3) farm organization, tenure, and labor supply, (4) farmers' attitudes toward A. A. A., and (5) payments made to farmers under the A. A. A. program for 1939."

**Farming in 1943**, E. B. HILL and C. O. MAY (*Michigan Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 189-199).—The essentials of a good farm-management program for 1943 are discussed in sections on subsistence and commercial farms under present conditions, size of business to handle, the soils and crops program, the livestock program, and farm expenses in 1943.

**A study of the newer hay harvesting methods on Ohio farms**, F. L. MORISON (*Ohio Sta. Bul.* 636 (1942), pp. [1]+16).—This study covered 167 north-western and east north central Ohio farms on which one or more of the newer hay harvesting methods were used in 1941. Eighty-four operators used auto buck rakes and 53 had buck rakes mounted on tractors. Pick-up balers were used on 23 farms, stationary hay choppers on 10 farms, and forage harvesters on 3 farms. Twenty-six operators used hay loaders. The buck rake was the cheapest way of getting hay from the windrow to mow. The large field choppers put chopped hay into the mow at approximately a 30 percent increase in the cost over the stationary chopper-buck rake method. Gathering and storing the bales took almost as much man labor per ton as the baling itself. The economies of the different methods employed in the cutting, baling, and storing of hay are otherwise compared.

**Cost of operating power equipment on Oregon farms**, C. D. MUMFORD, V. D. KENNEDY, and G. B. DAVIS. (Coop. U. S. D. A.). (*Oregon. Sta. Bul.* 409 (1942), pp. 32, figs. 4).—Data were obtained on the operation of 358 tractors, 155 combines, 150 trucks, and 370 automobiles and pick-ups in studies made in the Willamette Valley in 1938 and 1940 and in a wheat farm operation study in two counties in the Columbia Basin in 1941. The studies were made by the survey method. The farms in the Willamette Valley in 1938 were selected at random, but those in 1940 were limited to farms where Austrian Winter peas or vetches were grown. The farms in the Columbia Basin were selected as typical farms by the county agents. Analyses were made of the costs and factors affecting the costs of wheel and track types of tractors of different sizes, of combines of different sizes, of trucks and pick-ups, and of farm automobiles.

The largest tractors were the more expensive to operate on the basis of cost per hour but the cheapest on the basis of cost per horsepower hour. Use during the season and age were the most important items explaining the differences in cost per hour of operating tractors, season's use being the more important. In the Willamette Valley the "5-ft." power take-off combines were the cheapest to operate per acre and the "8-ft." combines with engines the most expensive. In the Columbia Basin the "20-ft." machines cost the least per acre and the "14-ft." machines the most. The cost of operating trucks and automobiles was affected materially by number of miles driven and age of machines. The older machines driven the most miles were generally the cheapest to operate if such factors as speed, efficiency, and dependability are not considered.

**A history of livestock raising in the United States, 1607-1860**, J. W. THOMPSON (*U. S. Dept. Agr., Agr. Hist. Ser.* 5 (1942), pp. VIII+182).—This history of animal husbandry in the United States includes chapters on the European background of American livestock; stock raising in Colonial New England, the Middle Colonies, the Southern Colonies, and in the United States, 1775-1830; the opening of the New West; the Spanish Southwest and California; the beginnings of stock raising in Oregon Territory and Utah, and stock raising in the United States during the middle era, 1830-60. Included are an extensive bibliography of the literature cited and selected references published since the author's manuscript was completed.

**Foreign Agriculture, [January 1943]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.* 7 (1943), No. 1, pp. 24, figs. 2).—An article, Australia's

**Agricultural Resources**, by W. I. Ladejinsky (pp. 3-21) describes the land and the people, topography, soils, climate, population, land use and tenure, etc.; the pastoral industry; and the production of wheat and other grains, hay, green forage, sugar, orchards and vineyards, tobacco and cotton, etc. The article attempts to reflect the real magnitude of the agricultural resources and to point out the factors limiting their expansion. It does not discuss the wartime agricultural problems. A second article, **Australian Agriculture and the War Effort** (pp. 22-24), discusses the pooling of agricultural reserves, the control of agricultural production and distribution, the conversion of production to meet war needs, and the reciprocal lend-lease aid being provided to the United States.

**The agriculture of Colombia**, K. H. WYLIE (*U. S. Dept. Agr., Foreign Agr. Bul. 1* (1942), pp. 160, figs. 45).—This is a comprehensive description and analysis of the present status and possibilities of agriculture in Colombia. It is based on many published works and many typewritten reports of the United States consuls in Colombia. The physical and economic background and the history, development, and general status of agriculture, including land policies, organization of the agricultural industry, self-sufficiency, and aids to agriculture, are described. The present status and possibilities for increasing the production of (1) export crops, especially coffee and bananas; (2) food crops—corn, beans, rice, potatoes, sugar, wheat, cacao, etc.; (3) raw-material crops—cotton, tobacco, fique, etc.; and (4) livestock are discussed. The section on foreign trade discusses the commercial policy, trade balances, exports and imports, the importance of the trade with the United States, the trade agreement with the United States, and the possibilities of expanding exports.

**1942 summary of outstanding Federal and State legislation affecting rural land use**, E. P. KILPATRICK and A. B. JEBENS (*U. S. Dept. Agr., Bur. Agr. Econ., L. E. Bul. 69* (1942), pp. [3]+44, fig. 1).—This summary includes the laws passed from January 1 to November 1, 1942. The Federal laws are grouped under the headings: Credit and insurance, grazing, marketing, services to agriculture, and water utilization. The State laws are grouped under the headings: Conservation, cooperatives, credit and insurance, forestry, Governmental cooperation, Governmental structure and administration, land tenure, marketing, public finance, public land administration, rural facilities, services to agriculture, taxation, water utilization, and zoning—planning. A State index is included.

**Land ownership and operating tenure in Imperial Valley, California**, A. POLI (*U. S. Dept. Agr., Bur. Agr. Econ., 1942*, pp. [2]+68, figs. 17).—The topography, soils, climate, population, irrigation development, and agriculture of the valley are briefly described. Land acquisition and settlement, types of land-ownership, size of ownership, instability of landownership pattern, types of farm operators, size of operating units, farm tenancy and related problems, and ownership-operating tenure relationships are analyzed and discussed. The labor situation is treated only in a general way in connection with phases of land tenure.

**Interstate migration and county finance in California**, T. V. JOHNSON and F. ARPKE (*U. S. Dept. Agr., Bur. Agr. Econ., Migration and Settlement Pacific Coast Rpt. 10* (1942), pp. [2]+50, figs. 6).—Total disbursements of county governments in California increased approximately 30 percent from 1930 to 1940, varying between individual categories from 13 percent for health and sanitation to 300 percent for charities and corrections. Growth of public expenditures is related to the increase in the number of people served and the type and quality of services extended. In Yuba County, interstate migration since 1930 accounted for 25 percent of the total 1940 population of 17,034, and was respon-

sible for public services costing \$257,513, or nearly 21 percent of a total expenditure in 1940 of \$1,244,036. In Kern County, property taxes increased \$3,029,088 between 1930 and 1940, and it is estimated that interstate migration was responsible for \$1,629,577 of this rise. In Yuba County, property taxes were actually \$17,849 less in 1940 than in 1930.

**Property tax burden of Tennessee farmers**, C. E. ALLRED and B. J. LUEBKE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 143 (1942), pp. IV+36, figs. 22*).—The types of taxes paid by farmers are described. The tax burden on different classes of property in the State and the equality of the property tax assessment ratios between counties, land classes, value classes, size of farm, etc., are discussed.

The percentage that taxes were of the value of farm real estate in 1939 ranged from 0.66 in Sullivan to 1.93 in Morgan County. Taxes actually paid per \$100 of real estate ranged from \$0.50 to \$4.33 for a group of 92 farms in a sample county.

**Meeting wartime marketing problems** (*Arkansas Sta. Bul. 428 (1942), pp. 42-45*).—Wartime marketing problems are discussed, including the marketing of fresh fruits and vegetables, peaches, canned tomatoes, and meat animals.

**Efficiency of the transportation of eggs to Connecticut cooperative associations**, W. J. HANSEN and R. G. BRESSLER, JR. ([*Connecticut*] *Storrs Sta. Bul. 241 (1942), pp. 35, figs. 10*).—In recent years, cooperatives have handled more than half of the eggs that go through wholesale channels in Connecticut, nearly a quarter of a million cases annually. Recommendations are made whereby, by pooling loads and in other ways it would be possible to reduce the miles traveled in transporting eggs by more than 80 percent.

**Marketing and pricing chickens in Kentucky**, J. B. ROBERTS (*Kentucky Sta. Bul. 433 (1942), pp. 47, figs. 19*).—This bulletin discusses the types and numbers of poultry marketed, how the prices for chickens are established and the effects of seasonal marketing on prices, the organization of marketing in country districts, the changes that have taken place in marketing methods, the relationship between volume of poultry and choice of market outlet, how dealer prices and farm prices are established, and the relationship between prices paid by different types of buyers.

**Report of the Administrator of the Agricultural Marketing Administration, 1942**, R. F. HENDRICKSON (*U. S. Dept. Agr., Agr. Market Admin. Rpt. 1942, pp. 83*).—The Administrator discusses the wartime marketing of farm products, lend-lease operations, domestic distribution, transportation, storage, marketing reports and statistics, standardization, inspection, marketing studies, and regulation.

**Report of the President of the Commodity Credit Corporation, 1942**, J. B. HUTSON (*U. S. Dept. Agr., Commod. Credit Corp. Rpt., 1942, pp. 24*).—Items discussed include Food for Freedom, Ever-Normal Granary, price supports, price ceilings, and foreign purchase programs.

**Seasonal variations of Indiana farm prices**, E. L. BUTZ (*Indiana Sta. Bul. 469 (1942), pp. 35, figs. 34*).—Tables and charts are presented and discussed showing for the more important Indiana farm products (1) the index of average seasonal variations in prices—"the price in any given month as a percentage of the annual average price," (2) the index of irregularity—"a measure of the amount of variation from the average for a given month that may be expected in a particular year," (3) times high or low—"the number of times for each month in the period being studied that prices were high or low for the year," (4) monthly movement—"the directional movement of prices from month to month," and (5) monthly marketings—"the percentage of total annual marketings of each commodity that moved from Indiana farms and from United States farms in each

month." The prices used are those reported as of the fifteenth of each month by the U. S. D. A. Agricultural Marketing Service. The percentages of products marketed were calculated from data from the office of the State agricultural statistician of Indiana. "The 10-yr. period, 1930-39, was used wherever possible in this study. In a few cases other periods were used for comparative purposes, and in the case of cattle the period 1926-39 was used in order to cover one complete cattle cycle." The products covered by the bulletin are hogs, cattle, calves, lambs, wool, eggs, chickens, butterfat and milk, wheat, corn, soybeans, oats, hay, potatoes, and apples. The methods used in calculating the general indexes are described.

**Consumption of milk and some other dairy products in metropolitan New Jersey, E. H. RINEAR** (*New Jersey Stat. Bul.* 702 (1942), pp. 15, fig. 1).—A total of 1,013 usable family records were obtained in a survey in the spring of 1941 in Highland Park, New Brunswick, Newark, and the Oranges. The data are analyzed by income ranges of \$500.

It was found that the consumption of fresh milk and other dairy products is directly related to family income. The consumption of fresh milk tended to increase as income increased from \$500 to \$2,500. The proportion of evaporated milk decreased as income increased. The consumption of fresh and evaporated milk combined approached the same level in low-income families as in higher income families. The consumption of butter and cream both increased with income level. The average adult in families without children consumed more fresh milk than adults in families with children. In general, growing children in the low-income families did not consume enough milk to maintain satisfactory standards of nutrition. "When the consumers were questioned regarding the desirability of quantity discounts and larger store differentials, a large proportion of those who were in favor of these methods had incomes below \$1,500. Also, they estimated that they would increase their consumption of fresh milk more than any of the other groups." There has been a steady increase in the consumption of evaporated milk during the past 20 yr., and unless new ways of distributing fresh milk are developed that will reduce cost to consumers, dairymen supplying fresh milk for immediate consumption may find a continued decreasing demand for their product.

**Maintaining quality of Oregon late-crop potatoes in retail markets, D. B. DeLoach** (*Oregon Sta. Bul.* 410 (1942), pp. 7).—In cooperation with the State Department of Agriculture, a survey and sampling of 1941 crop year potatoes was made in 200 retail stores selected at random in Portland, Oreg., and the cities of the San Francisco Bay area of California. An attempt was made to determine the cause or causes for the deterioration in the quality of the potato sample below the grade established at the shipping point.

This bulletin briefly states the findings of the 1941 survey and makes comparisons with those in the first survey made in 1940 (E. S. R., 88, p. 121). Findings are discussed under the headings of deterioration caused by improper handling and merchandising, short-weight containers, size of consumer purchase as influenced by prices, and uniform sizes of potatoes in demand. Points to be considered in an educational program and rules for the care of potatoes are presented.

**Trends in demand for tobaccos of the Southern States, R. S. WHITE, JR.** (*Kentucky Sta. Bul.* 431 (1942), pp. 82, figs. 18).—This is a comprehensive study and description of the important factors affecting the consumption and demand for various tobaccos produced in the Southern States. World production, kinds of tobacco, and the place of tobacco in the economy of the United States are described briefly. Statistical and other data are analyzed and discussed in sections

on production, disappearance, and prices; domestic demand and consumption; tobacco exports by types and major areas of destination; some general factors affecting exports of United States tobaccos; Government policies affecting tobacco industries of foreign countries; factors affecting the foreign demand for American flue-cured tobacco, for fire-cured and dark air-cured tobacco, and for Burley and Maryland tobaccos; and tobacco exports and the present war.

## RURAL SOCIOLOGY

**Wartime migration from the rural Spanish-speaking villages of New Mexico, C. P. LOOMIS** (*Rural Sociol.*, 7 (1942), No. 4, pp. 384-395, figs. 5; *Span. abs.*, p. 384).—Between 1939 and September 1942 there has been a decrease of almost half in the number of men and boys 15 to 65 yr. of age in 24 Spanish-speaking villages in four New Mexico counties. Some villages have lost 70 percent of their male population in these age groups. Altogether, between one-half and two-thirds of these migrants are in the armed forces, working on wartime defense projects, or engaged in reopened mines and other new work. Farmers and ranchers who customarily depend upon these people as a source of labor supply must now seek other means of getting much of their work done.

**In quest of free land, A. SCHOCK** (*Rural Sociol.*, 7 (1942), No. 4, pp. 431-443; *Span. abs.*, pp. 431-432).—Compulsory military service in Russia and free land in America induced many Russian-Germans to settle in the Dakota Territory. Within a few decades they had turned prairies into wheatfields and farms. The early sod huts were soon replaced by frame houses and huge barns. Their community life had all the characteristics of a pioneering group. They were a hardy folk. The church and saloon were rival institutions. Some of the early trading posts and country stores grew into small towns and villages. In their highly homogeneous life the solidarity of the family constituted the basic social unit. The home and the church played dominant roles in social control. They retained the mores of the Old World and remained unassimilated until the World War of 1914 when cultural fusion began.

**A comparative analysis of the people on new ground farms, plantations, and old family farms in the upper Mississippi Delta of Louisiana, H. L. HIRT** (*La. Expt. Sta. and U. S. D. A.*). (*Rural Sociol.*, 7 (1942), No. 4, pp. 404-414, fig. 1; *Span. abs.*, p. 404).—The aim of this analysis, which is based on a sample of 660 schedules obtained in 1939, is to point out some of the similarities and differences between the recently settled new-ground families and their neighbors residing on plantations and on the long-cultivated family-size farms of the upper Mississippi Delta of Louisiana. White farmers are in a decided majority on the cut-over new ground, but in a minority on both the plantations and old family-size farms. The resultant increase of whites may exert a significant influence on local government. New-ground farms as compared with plantations attract young farmers in disproportionately large numbers. The families of these young farmers are relatively large and decidedly more often include husband, wife, and children, with and without others. The housing on the new ground as compared with that on plantations and the old family farms is most inadequate for both racial groups. The inferior material level of living of the white new-ground families is also suggested by their less frequent possession of certain material goods.

**Some aspects of cultural conflict and acculturation in southern rural Brazil, E. WILLEMS** (*Rural Sociol.*, 7 (1942), No. 4, pp. 375-384; *Span. abs.*, p. 375).—In Brazil there is a deep gap between the urban centers with their dependent rural areas, and the other rather self-sustaining part of the rural

population which early developed a peculiar folk culture under the impact of special environmental conditions. Besides industrialization it is chiefly foreign immigration which produces cultural clashes between highly organized immigrant groups and Brazilian rural folk. The two areas studied are the Ribeira Valley in the State of São Paulo settled by Japanese, and the Itajahi-Mirim Valley in the State of Santa Catharina settled by German immigrants. Contacts with the native rural population lead to cultural conflicts, since social values and social organization are strongly opposed in many of their major spheres. The growing industrialization process increases the social disorganization of the native workers, but disorganizes also the rural communities established by German immigrants.

At present, the Japanese community is in transition to more individualistic patterns of economic organization. Culture conflicts occur chiefly in the educational sphere. As a result, traditional controls are breaking down and the Japanese patriarchal family is giving place to a more individualized family organization.

**Mistakes to be avoided in meeting labor crisis in coming year revealed by study,** R. W. ROSKELLEY (*Colo. Farm Bul.* [*Colorado Sta.*], 5 (1943), No. 1, pp. 4-5).—The major fields in which improvements can be made are (1) more effective use of present labor supply and (2) development and perfection of ways of locating, recruiting, training, and using potential reserve labor supply.

**Standard of living: An empirical test of a definition,** H. R. COTTAM and A. R. MANGUS. (Pa. State Col. and Ohio Expt. Sta.). (*Rural Sociol.*, 7 (1942), No. 4, pp. 395-403; *Span. abs.*, p. 396).—This article describes an empirical test of the hypothesis that level of living, social participation, and social adjustment are components of a broader concept, standard of living.

**Local leadership in rural communities of Cumberland County, Tennessee,** H. J. BONSER, R. G. MILK, and C. E. ALBRED (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog.* 144 (1942), pp. V+79, figs. 6).—The authors conclude that in Cumberland County personalities are very often as important as issues in deciding the immediate course of an organization. In some groups the strongest leaders at times hold no office. Leaders tended to be older than the average of all people and are somewhat better educated than the adult population as a whole.

Personal influences of individuals were reported most frequently as factors helpful to these leaders in their work. Other factors prominently mentioned were literature, home training, church and Sunday school, occupational experience, special courses in school, and experience in other organizations. Of the general traits mentioned as desirable in leaders, conformity to the established modes of conduct was considered by far the most important. Other traits mentioned were identification with the group interested; honestly, faithfulness, and sincerity; and aggressiveness. Desirable traits less frequently mentioned were ability of expression, education, tact, experience, strength, good judgment, and the motive for service. Leaders who had at some time taught school offered more suggestions for developing leaders and coping with community problems than did leaders from other occupational groups. The consensus of opinion among leaders studied was that leadership has improved somewhat in this area in the last 10 years. The main reasons given for improved leadership were higher caliber school teachers and the influence of agricultural and home economics representatives in the county.

There was a positive relationship between leadership improvement in neighborhoods and such factors as number of organizations in which leaders held membership, occupational experience of leaders, education of leaders above the high

school level, attendance at conferences, type of organizations found in the neighborhood, and youthfulness of leaders.

**Community organization and adult education**, E. DES. BRUNNER (*Chapel Hill: Univ. N. C. Press, 1942, pp. IX+124*).—This is a report of a 5-yr. experiment in community organization and development on a county-wide scale in Greenville County, S. C.

**The community church as a sociological form in New York**, W. A. ANDERSON and R. WILLIAMSON. (Cornell Univ.). (*Rural Sociol.*, 7 (1942), No. 4, pp. 415-423; *Spann. abs.*, p. 415).—The nondenominational community church arises as a sociological form in new areas of population concentration, in areas of insufficient population to support a denominational church, or where negligence of denominational churches occurs. The pattern of organization, though not uniform, is of the congregational type. The religious program of such a church is practically identical with those of denominational churches, and for leadership and membership these churches are dependent upon denominational sources. As denominational churches develop interdenominational cooperation through federated churches, exchange of church fields, and larger parishes, this type of church may cease to arise as a distinct form.

**The challenge to democracy.—VIII, The machine and democracy**, C. H. NORBY (*Iowa Sta. Bul. P28, n. ser. (1942), pp. 733-748*).—This is the final article of the series (E. S. R., 87, p. 445). The author discusses industrialism and world politics and calls attention to (1) the rise of England as the workshop of the world and (2) the opportunities and dangers of our part in international politics.

## FOODS—HUMAN NUTRITION

**Outlines of food technology**, H. W. VON LOESECKE (*New York: Reinhold Pub. Corp., 1942, pp. 505, figs. 84*).—This book describes briefly the more important processes used in the modern food industry. As a guide to more detailed and specific information pertaining to any particular field, a list of suggested readings is appended to each chapter. Consideration is given to the tin can and the glass container, and the processes outlined pertain to the following: Fruits and their products; canning of vegetables; dairy products; meat, meat products, and poultry; fish and shellfish; grains and their products; edible fats and oils; sugars and starches; nuts; spices, relishes, essential oils, and extracts; beverages; confectionery, jams, jellies, preserves, and certified dyes; storage and marketing of fruits and vegetables; and preservation of foods by freezing.

[**Food and nutrition investigations at the Arkansas Station**] (*Arkansas Sta. Bul. 428 (1942), pp. 19-22*).—This progress report summarizes briefly the findings of studies, some of which have been noted previously, of the carotene content of peaches, by H. Reynolds and J. R. Cooper; the effect of processing on the ascorbic acid content of tomato juice, by Reynolds; the digestibility and the biological and supplemental values of rice proteins, and the thiamin content of rice and rice milling products, by M. C. Kik; and the relationship of thiamin and riboflavin deficiencies, by B. Sure.

**Classification of foods, and factors for conversion of their packaging units to pounds**, P. E. HOWE, C. S. PRITCHETT, and G. H. BERRYMAN (*Jour. Amer. Dietet. Assoc.*, 18 (1942), No. 7, pp. 435-448).—Tables designed for use in connection with rapid evaluation of diets are presented to show the common units in which foods are purchased, the weight of such units (converted also to the uniform basis of pounds), and certain conversion factors. In the tables the foods are arranged by classes or groups on the basis of similar nutritive content or unique contribution to the diet. The classes are as follows: Meats,

eggs, milk and milk products, fats (butter), other fats, cereals and grain products, beans and other legumes (dry), sugars and sirups, leafy green or yellow vegetables, tomatoes, citrus fruits, potatoes (Irish), other vegetables, fruits (other than citrus), dried fruits, beverages, and miscellaneous.

"It is therefore possible to obtain a rapid estimate of any diet by determining the amounts in pounds per man or 100 men per day of the various classes of foods, and then comparing these quantities with an acceptable standard. By applying weighted group averages for nutrients to these figures, an approximate quantitative estimation of the various nutrients will be obtained. Comparison and evaluation will be facilitated if stock records and lists of foods accompanying menus are classified in accordance with this plan."

**Chemical composition of twenty-two common foods and comparison of analytical with calculated values of diets**, F. C. HUMMEL, M. L. SHEPHERD, H. GALBRAITH, H. H. WILLIAMS, and I. G. MACY (*Jour. Nutr.*, 24 (1942), No. 1, pp. 41-56).—Average values, based on analyses of 5 (or fewer) to as many as 27 samples of each of 22 commonly used foods, are reported for the content of energy, fat, C, N, Ca, Mg, Na, K, P, Cl, S, and Fe per 100 gm. of edible portion. The determinations showed that individual samples of a given food varied from the values reported in standard tables. Na and Cl, components of extracellular fluid, varied the most widely from the values in standard tables, while K, which is an intracellular constituent, differed less from previously reported values than any other mineral constituent determined. Milk was found to be the most constant in mineral composition, but fruits and vegetables varied widely. The composition of 11 diets composited from the various foods analyzed in this study was estimated from data on the composition of these foods and was also determined by actual analysis of the composite. The composite diets as analyzed showed a more constant composition than the components, thereby emphasizing the increased accuracy which may be obtained when a large amount of a given constituent is contained in the material available for analysis. When the analyses of composite diets were compared with the dietary figures calculated from the literature there was found to be good agreement in the content of Mg, K, P, S, calories, and fat, while calculated Ca intakes were significantly higher than the determined values and Na and Cl intakes were decidedly lower. It is pointed out that for highest accuracy in dietary studies individual foods or the composite diet involved should be analyzed under the conditions of the experiment.

**The food value of mushrooms (*Agaricus campestris*)**, E. E. ANDERSON and C. R. FELLERS. (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 301-304).—Mushrooms of the commercially cultivated species *A. campestris*, examined for vitamin content by methods noted, were found to contain the following amounts per 100 gm.: Vitamin A none, thiamin 0.12 mg., riboflavin 0.52, ascorbic acid 8.60 mg., vitamin D none, vitamin E none, vitamin K + +, nicotinic acid 5.85 mg., and pantothenic acid 2.38 mg. K and P salts are reported to have been the chief constituents of the ash, with no significant amounts of Ca but with Cu and Fe present in relatively appreciable amounts. When rats received mushrooms as a sole source of protein in their diet, they survived a 6-week test period and made a gain in weight equivalent to 30 percent of that obtained by rats on a casein positive control diet.

**What enriched white bread means to America**, J. L. K. SNYDER (*Bakers Digest*, 16 (1942), No. 10, pp. 226-228).—This address stresses the importance of enriched bread to the consumer and the benefits accruing to the baker.

**Microbiology of meats**, L. B. JENSEN (*Champaign, Ill.: Garrard Press, 1942*, pp. XI+252, [pl. 1], figs. [7]).—This book deals with the industrial micro-

biology of meat foods, the academic features of bacteriology being introduced as they fit into the practical picture. The terminology is that familiar to operating men, and the presentation of data is that of practical meat operations, i. e., the flow-sheet method of times, temperatures, substrates, and number of species of organisms. The scope of the work is indicated by the chapter headings as follows: Introduction and history; some effects of sodium nitrate on bacteria in meat; gaseous fermentation in meat products by the genus *Bacillus*; bacteriology of green discolorations in meats; action of micro-organisms on fats; a study of ham souring—ante mortem and post mortem studies on the bacteriology of normal tissues of swine; microbiology of beef; bacteriology of sausage; microbiology of bacon; control of micro-organisms; bacteriology of spices, salt, sugar, paper, and wood; and a summary of food poisoning of bacterial origin. The numerous literature citations are given by footnote.

**The relation of ultra-violet light and temperature during aging to quality of beef,** I, J. A. McINTOSH, J. SOTOLA, M. BOGGS, J. ROBERTS, C. C. PROUTY, and M. E. ENSMINGER (*Washington Sta. Bul.* 422 (1942), pp. 26).—The effect of ultraviolet lamps on the microflora of beef was observed in tests endeavoring to speed up the aging of beef by the use of higher temperatures and humidity, these conditions being more economical and resulting in less discoloration and dehydration than the low temperatures and humidities generally used. Short loins of beef were irradiated at distances of 46 cm. for periods of 7 and 14 days, with daily rotation, at temperatures of 34°–50° F. and relative humidities of 65 and 90 percent. The irradiated loins were compared with nonirradiated loins by cutting them into steaks and subjecting them to cooking tests in which they were scored on various points. It was found that the use of ultraviolet rays of 2,537 a. u. reduced the surface microflora. Under the conditions of the experiment, however, excessive bacterial development did not occur even in the absence of ultraviolet light. Exposure of beef short loins to Sterilamps at 34°–50° for 7 and 14 days at about 90 percent r. h. darkened the color, imparted a greasy appearance to the tallow, and caused greater shrinkage (3.02–5.99 percent) than occurred in loins not exposed to the light (1.71–4.90 percent). Light treatment did not affect total cooking losses (drip and evaporation), which varied from 14.4 to 15.0 percent for steaks aged 7 and 14 days and stored 6 mo. at 0° before cooking. Aging for 7 and 14 days at 34° increased the intensity of flavor in both the light-treated and untreated series and reduced the desirability of both cover and kidney fats.

Increase in rancidity of the fats, as judged by palatability tests, occurred upon storage of the loins and steaks at 0° for 6 mo.; flavor of the lean and quantity and desirability of the juice were relatively unaffected. The ultraviolet light had no significant effect on tenderness, whereas frozen storage for 6 mo. at 0° had a slight tendering effect on good-quality beef. Vitamin D assays by the U. S. P. rat technic indicated that the beef tallow contained some vitamin D, and that the concentration was not appreciably affected by exposure of the tallow to ultraviolet light for either 10 sec. or 7 days at a distance of 46 cm.

**Effect of various cooking methods upon subjective qualities and nutritive values of vegetables,** E. V. S. BRINKMAN, E. G. HALLDAY, W. F. HINMAN, and R. J. HAMNER (*Food. Res.*, 7 (1942), No. 4, pp. 300–305).—The cooking utensils chosen included (1) an enamelware open kettle in which vegetables were boiled in a comparatively large quantity of water, (2) two types of aluminum "waterless" cookers permitting the cooking of vegetables in their own juices or in a very small quantity of water, and (3) a small aluminum pressure saucepan in which vegetables were cooked in steam at 15 lb. pressure.

Vegetables, including carrots, green beans, peas, asparagus, spinach, green cabbage, broccoli, cauliflower, and turnips, were cooked according to standard procedures or directions accompanying the cookers, after which they were scored and analyzed to determine the relative effectiveness of the various cooking procedures in retaining color, flavor, texture, odor, and nutritive constituents (Ca, P, and ascorbic acid) of the vegetables. The quality scores indicated that no general conclusion could be drawn that would apply to all vegetables cooked in any one type of utensil. The small pressure saucepan appeared to be as satisfactory as the open kettle for cooking carrots, turnips, and all green vegetables except asparagus, which was inferior in color and flavor when cooked in the pressure saucepan; peas thus cooked were superior in color. The pressure saucepan, however, seemed to be less desirable for cabbage, broccoli, and cauliflower. The waterless cookers produced satisfactory products only with carrots and green beans cut in strips. Calcium retentions in all methods for all vegetables ranged from 87 to 121 percent, with no one method highest in all cases; the increases in Ca occurred in beans and peas because of their absorption of Ca from the cooking water, which contained as much as 30 p. p. m. Phosphorus retentions by all methods of cooking varied from 60 to 92 percent and ascorbic acid retentions from 40 to 70 percent. Again no one method was superior for all vegetables, but on an average the pressure saucepan had a slight advantage over the other methods.

**Preservation of fruits and vegetables by freezing,** G. A. FILINGER. (Kans. Expt. Sta.). (*Kans. State Hort. Soc. Bion. Rpt.*, 46 (1940-41), pp. 27-30).—This paper, based on unpublished data from the department of horticulture and published work from many sources, presents information on problems connected with the preservation of foods by freezing. Factors considered are suitable kinds and varieties of fruits and vegetables, containers, suitable packing methods, freezing temperatures, storage facilities, and uses of frozen products.

**Chemical, histological, and palatability changes in pork during freezing and storage in the frozen state,** C. L. SHREWSBURY, L. W. HORNE, W. Q. BRAUN, R. JORDAN, O. MILLIGAN, C. M. VESTAL, and N. E. WEITKAMP (*Indiana Sta. Bul.* 472 (1942), pp. 36, figs. 6).—Pork loin roasts and chops from firm and soft carcasses were frozen in a Birdseye multiple froster at  $-26^{\circ}$  F. and were stored at  $-6.3^{\circ}$ ,  $-8.4^{\circ}$ , and  $-8.2^{\circ}$  for three experiments, respectively. Findings concerning the changes in the pork during freezing and during storage for periods up to 16 mo. are discussed and are summarized as follows:

"Ammonia nitrogen of the lean tissue increased to a maximum at 6 months' storage and then decreased but did not reach a value indicative of spoilage. The pH values of the lean tissue probably did not change significantly during the period of observation. Desiccation of the lean tissue due to loss of moisture was slight. Peroxides, free acidity development, refractive index, iodine values, saponification numbers, and titer values of the fatty tissue showed no important changes within the intervals studied that would indicate rancidity development or chemical decomposition of the fat during freezing and subsequent storage. Antioxidants of the fat decreased during the term of the experiments. The intensity of the factors of palatability were not affected to any important degree by freezing, or storage after freezing up to 12 or 16 mo. Desirability of flavor of fat scores showed a trend toward less desirability for storage periods of the frozen samples of 8 mo. or longer. Desirability of flavor of lean scores showed a slight downward trend with increased length of storage period.

"A highly significant correlation was found between the palatability committee scores for tenderness and the tensile strength values of the roasts as determined by the shear machine. There was no definite effect on tenderness

of roasts or chops that could be related to freezing or storage. Freezing and storage after freezing had no marked effect upon the cooking losses of the roasts and chops used in this study. Fresh muscle tissue appeared relatively normal in structure, although shrinkage in various degrees was noted and was manifest by a separation of the sarcoplasm from the endomysium. Under the conditions of freezing ( $-26^{\circ}$ ) both intra- and extracellular freezing damage of the tissue was observed. Tissue stored frozen for periods of 4, 8, 12, and 16 mo. appeared similar to frozen unstored tissue with respect to damage from intracellular freezing. Damage of the tissue during storage was of a progressive nature. Adipose tissue gave no evidence of damage during freezing or subsequent storage in the frozen state. The chemical, palatability, and histological studies showed that pork from firm and soft carcasses had similar keeping qualities. The combined studies demonstrate that pork frozen and stored under the conditions of these experiments was in a very satisfactory condition at the end of 1 yr. and was edible at the end of 16 mo."

**Effect of fast-freezing upon bacterial flora of mackerel**, J. S. KISER and T. D. BECKWITH. (Univ. Calif. et al.). (*Food Res.*, 7 (1942), No. 4, pp. 255-259).—"The bacterial flora of the muscle and intestinal contents of mackerel is reduced sharply by freezing and storage at  $-28^{\circ}$  C. for 10 days. Freezing and storage for 48 hr. at  $-28^{\circ}$  produced a greater decrease in numbers in suspensions of bacteria isolated from mackerel than did a similar freezing and storage period at  $-20^{\circ}$ . Freezing and storage at  $-20^{\circ}$  for 15 days resulted in an approximate 100-percent decrease in suspensions of *Achromobacter* sp. used, but the micrococci withstood the low temperature much better."

**Home canning of fishery products**, N. D. JARVIS and J. F. PUNCOCHAR (*U. S. Dept. Int., Fish and Wildlife Serv., Conserv. Bul.* 28 (1942), pp. 11+31, figs. 3).—This bulletin, superseding Investigational Report No. 34, revised (E. S. R., 86, p. 414), presents detailed information to assist homemakers to can difficult fishery products safely and economically. Consideration is given to the principles involved in canning sea foods, to equipment requirements, canning procedure, and recommended canning methods for specific fish and shellfish. Certain fishery products unsuitable for canning are noted, and a word of caution is given concerning tasting for suspected spoilage.

**Dehydration of foods in war-time**, W. V. CRUESS. (Calif. Expt. Sta.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 22 (1942), No. 4, pp. 105-107, 118, fig. 1).—This paper considers very briefly the advantages of dehydration, the need for dehydrated foods, and certain principles and problems involved in dehydration. A number of agencies now carrying on research on dehydration problems are noted.

**Texas begins dehydrated food research**, S. H. YARNELL. (Tex. Expt. Sta.). (*Canner*, 96 (1943), No. 6, pp. 54-55).—This is a brief statement of the scope of work being done by the station on the dehydration of Texas-grown vegetables. Preliminary drying tests with cabbage, carrots, potatoes, mustard greens, onions, snap beans, and spinach indicated that attractive products of good quality can be obtained. Beets and rutabagas are also to be tested. The products are being tested not only for quality but for vitamin content as well.

**Preserving nutritive value in drying food is goal of project; dehydrator plan given**, W. E. PYKE and R. BARMINGTON (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 4, pp. 10-11, figs. 2).—The compact highly satisfactory dehydrator built at the station is of the tunnel type modified to fit into a portable cabinet and equipped with a gas heater of the direct radiation type. Cherries, potatoes, corn, beans, peppers, beets, and carrots have been satisfactorily dehydrated, and carotene analyses of the carrots showed that the dehydrated product contained

more than 2,500  $\mu\text{g.}$  of carotene per gram, in comparison with 25  $\mu\text{g.}$  per gram in the fresh carrots.

**Dehydration of olives,** W. V. CRUESS and H. F. FRIAR. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 22 (1942), No. 4, pp. 116, 124).—On the basis of certain recent investigations, it is recommended tentatively that dead ripe Mission and Manzanillo olives be treated one-half to three-fourths to the pit with lye, rinsed in water, soaked in brine, and dehydrated to less than 10 percent moisture. The aim is to give a product which can be reconstituted quickly in boiling water to give a relish, or which can be used directly in cookery as a flavoring.

**Dried vegetables are made into "bricks" freed from air in new packaging process to insure color, flavor, and nutritive value** (*Farm Res. [New York State Sta.]*, 9 (1943), No. 1, p. 17).—Dried carrots, beets, cabbage, sauerkraut, and other products are subjected to tremendous pressure to reduce the materials to small bricks practically free from air. The effectiveness of various packaging materials in protecting these bricks against spoilage under such simulations of tropical conditions as holding the packages in tanks of water or storing them at a temperature of 100° F. and at a humidity of 85 percent is being tested bacteriologically, by determining loss of vitamin content, and by other means. The gasproofing qualities of the packaging materials are also being studied.

**An analytical study of cucumbers and cucumber pickles,** L. J. CAMILLO, C. A. HOPPERT, and F. W. FARIAN. (Mich. Expt. Sta.). (*Food Res.*, 7 (1942), No. 5, pp. 339–352; *abs. in Mich. Sta. Quart. Bul.*, 25 (1943), No. 3, pp. 272–273).—Determinations of proximate constituents, minerals (Ca, P, Fe, and Cu), and vitamins (A, thiamin, riboflavin, ascorbic acid, and D) were made by methods noted in fresh cucumbers and various types of pickles made from them by commercial processes. Total solids in all varieties of pickles were higher than in the cucumbers from which they were made, this increase being particularly pronounced in sweet pickles and bread-and-butter pickles, due to materials added in the course of manufacture. Protein, Ca, and P values for pickles showed a decrease as compared with the fresh cucumbers, and in the fermented pickles (genuine dill and salt-stock pickles) reducing sugars were removed during the first 4 days of fermentation. The carotene content of pickles, as determined by the method of Peterson et al. (*E. S. R.*, 85, p. 583) or of Petering et al. (*E. S. R.*, 83, p. 438), was higher than in the fresh cucumbers in which values calculated to International Units ranged from 166 to 290 per 100 gm.; the increase in values ranged from 23 percent in pasteurized dill pickles to 261 percent in salt-stock pickles. In the fresh cucumbers, ascorbic acid, expressed as International Units per 100 gm., ranged from 234 to 293, and the amounts of thiamin and riboflavin were low. The amounts of these water-soluble vitamins decreased in the pickles, the decrease amounting to from 33 to 87 percent in dill pickles, from 12.5 to 40 percent in pasteurized dill or bread-and-butter pickles, and from 75 to 86 percent in salt-stock pickles. A determination of the biological value of the carotene fraction extracted from a sample of spiced pickles indicated a value of 80 percent of the color value expressed as  $\beta$ -carotene. The carotene content of the various kinds of commercial pickles obtained from manufacturers from different parts of the country varied from 20.4 to 103.2  $\mu\text{g.}$  per 100 gm. (27.2–137.6 I. U.), while the ascorbic acid, determined by the method of Moore and Ely (*E. S. R.*, 86, p. 586), ranged from 62 to 236 I. U. per 100 gm.

**The fate of enzymes in processed foods,** A. K. BAILS. (U. S. D. A.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 22 (1942), No. 2, pp. 36–39).—This paper presents some of the useful information available on the fate in food processing of enzymes responsible for deterioration and decay. Gas storage, low-tempera-

ture storage, drying and heat, or combinations of these, destroy enzymes. In practice, therefore, tissues must be blanched. The blanching must be relatively thorough, or else subsequent storage must be relatively cold or very dry. Heating, in this case blanching, inactivates the enzyme through action on its protein component, which is denatured by the heat. This denaturation is not always permanent, and the protein may revert on cooling to its native state; this occurs especially if the heating is brief, followed by rapid cooling and storage in a medium of favorable pH. To prevent this protein reversion, i. e., to prevent enzymes from reappearing later on, the blanching must be done for a sufficient length of time, since long heating is more destructive of the enzyme proteins than brief high temperatures. Experience with blanched products in food industries indicates that certain enzymes of this group are capable of causing discoloration and off-flavors. The substances responsible for these effects are often intermediate products formed in the course of a series of enzyme reactions; when the chain of reactions is interrupted by destruction of one of the enzymes, the intermediate product may accumulate rather than  $\text{CO}_2$  or  $\text{H}_2\text{O}$ , the end products of the reaction. In food processing it is desirable to test for the survival of typical enzymes. The indicator enzyme chosen must lend itself to easy testing, must not be too easily destroyed by heat, and should be known to recover some of its activity on cooling; the test should be roughly quantitative to enable setting up a graded scale of enzyme inactivation. Phosphatase for milk and peroxidase for some fruits and most vegetables are enzymes meeting these conditions. Total destruction of the enzymes in a food is usually not practical or necessary, but subsequent storage conditions must be at temperatures and humidities low enough to slow down the residual enzyme action to the point where the product keeps satisfactorily.

**Better food for our children**, A. F. MORGAN (*Hygeia* [Chicago], 20 (1942), No. 11, pp. 848, 871).—This article indicates briefly some of the steps that have been taken toward improvement of the nutrition of pupils through the school lunch program and estimation of nutritional status in the course of physical examination, and suggests that the educational attack on the problem is through the schools with the educational process including not only the pupils but also parents, teachers, doctors, nurses, dentists, principals, and school boards.

**Nutrition and chemical growth in childhood.**—I, Evaluation, I. G. MACY (Springfield, Ill.: Charles C. Thomas, 1942, vol. 1, pp. XXIV+432, figs. [67]).—The work of the author and her associates, conducted over a period of 20 yr. in connection with investigations of the processes of human growth and maintenance, are assembled from many published sources and evaluated for presentation in this monograph. A second volume, Interpretation, is projected. The organization of material is indicated by the chapter headings as follows: General considerations in metabolic balance studies, organization of an extensive metabolic investigation, satisfying appetite and meeting recommended dietary allowances, some physiological aspects of digestion and excretion, some chemical aspects of digestion and excretion, energy metabolism in childhood, metabolic balances, hematochemical studies, and methods.

The earlier investigations dealt with the phenomena of the reproductive cycle, the mineral metabolism of mothers during various stages of pregnancy and lactation, and the composition and secretion of human milk. The metabolism of normal women was also studied. The more recent work, dealing with nutrition and chemical growth in childhood, included study of the intake and excretion of 18 chemical substances by normal children, supplemented with pediatric, anatomic, psychometric, physiologic, anthropometric, roentgenologic, and chemi-

cal observations. Technics for efficient and economical conduct of investigations of human subjects, accurate chemical and physicochemical methods, simple reliable methods of recording voluminous data, and improved methods available for handling and interpreting the values obtained by experimental procedures were developed in the course of the investigations.

**Dietetics for the clinician.** M. A. BRIDGES (*Philadelphia: Lea & Febiger, [1941], 4. ed., rev., pp. 960, [figs. 6]*).—In the present edition (*E. S. R., 70, p. 868*) revisions in the first part, which deals with general information, include the introduction of a lengthy discussion of acid-base factors in nutrition, and an extensive change in the vitamin section, which presents an account of certain historically significant developments; a practical working basis of this phase of nutrition; and a glossary of vitamin terms giving condensed information. In the second part, dealing with the dietary management of diseases, one of the most conspicuous changes is the substitution of typical diets for the sample menus heretofore used. These typical diets are all based on the standard normal from which they deviate as little as possible. Part 3, pediatrics, has been omitted from the present edition. Some material on the management of diseases of children, but none on normal infant feeding, is included in part 2.

**Calcium, phosphorus, and nitrogen metabolism of young college women.** H. MCKAY, M. B. PATTON, M. A. OHLSON, M. S. PITTMAN, R. M. LEVERTON, A. G. MARSH, G. STEARNS, and G. COX. (Ohio, Nebr., Iowa, Kans., and N. C. Expt. Stas. et al.). (*Jour. Nutr., 24 (1942), No. 4, pp. 367-384, figs. 3*).—This report, presented as paper No. 15 of the regional project of the North Central States relating to the nutritional status of college women, deals with Ca, P, and N intakes and retentions of (1) 124 college women from four States (Ohio, Nebraska, Iowa, and Kansas) on their customary self-chosen diets; (2) an individual for forty-four 5-day periods at intervals during her nineteenth through her twenty-second year; and (3) a group of 9 young women eating controlled basal diets supplemented daily with 1, 2, or 3 cups of milk, respectively. The results showed that place, age, and weight differences were not significant for the 124 subjects, and that intake was significantly related to retention. Mean daily retention varied among individuals on similar intakes. Figures of regression of balance upon intake showed that mean daily intakes of 0.8 gm. Ca, 1 gm. P, and 9 gm. N, respectively, were required for equilibrium in the groups of 124 and 9 subjects. With intakes of Ca less than 0.8 gm., only 43 percent of those on self-chosen diets showed a storage of this element as compared with 70 percent of those on the controlled diet; similarly, at Ca intakes above 0.8 gm., 70 and 82 percent of these two groups stored Ca, with corresponding retentions of 0.055 and 0.070 gm. This superior retention associated with type of diet (self-chosen v. controlled with milk supplement) was also evidenced to some extent in the case of P retention. There was no evidence of better utilization of N by those on controlled diets than by those on the self-chosen diets. The one subject studied intensively required 1.1 gm. Ca, 1 gm. P, and 8 gm. N for equilibrium, these amounts being higher than the mean figures for the group average.

The response of the young women in these several groups suggests the desirability of a generous Ca allowance; the 1-gm. allowance recommended by the Committee on Food and Nutrition of the National Research Council for girls of from 16 to 20 yr. is considered desirable for this older age group of from 17 to 24 yr. Since the Ca, P, and N retention relationship for the large group was similar to the relationship commonly accepted whereas that for the single individual was not, it is considered that a short-time study of a large group is

more desirable than the intensive study of one individual in estimating population needs.

**Length of the observation period as a factor in variability in calcium retentions.** H. MCKAY, M. B. PATTON, G. COX, M. A. OHLSON, M. S. PITTMAN, R. M. LEVERTON, A. G. MARSH, and G. STEARNS. (Ohio, Nebr., Iowa, Kans., and N. C. Stas. et al.). (*Jour. Home Econ.*, 34 (1942), No. 9, pp. 679-681).—This report, based on the data obtained in the study noted above, is listed as paper No. 14 of the regional project noted above. The Ca intake and retention data of the young college women on their customary self-chosen diets were studied for variance due to differences in length of observation period. An analysis of variance and covariance was made by the method of Snedecor, and the mean square of retention, when adjusted by means of regression to a mean intake, was used as the measure of variance. The F test was used to determine significance of differences in mean squares. For 109 of the individuals, for whom there were 180 studies, the variance was significantly less in either 7- or 10-day observation periods than in the 5-day periods. The difference between the 7- and 10-day periods was not significant, so that of the three periods the 7-day period is considered the most practical.

**The mechanism of the effect of calcium salts on the succinoxidase system.** K. F. SWINGLE, A. E. AXELROD, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 145 (1942), No. 2, pp. 581-591).—Evidence is presented in support of the hypothesis that "calcium stimulates the succinoxidase system by activating the cozymase nucleotidase present in the tissue so that cozymase is destroyed and cannot function in the dehydrogenation of malate to oxalacetate, which is strongly inhibitory to the succinoxidase system."

**Trace elements in foods.** H. O. CALVERY (*Food Res.*, 7 (1942), No. 4, pp. 313-331).—This address before the American Public Health Association in October 1941 is based on a review of the literature and is concerned with the occurrence, nutritional value, and toxicity of a number of elements occurring in small quantities in foods. These included the nutritive trace elements Co, Cu, Fe, I, Mn, and Zn; nonnutritive, nontoxic trace elements, Al, Be, B, Cr, Si, Sr, Sn, Ti, and Ni; and nonnutritive, toxic trace elements, Ag, Bi, Cd, F, Hg, Pb, As, Sb, Ba, Br, Se, Te, Mo, V, and Tl. It is pointed out that Cs, Ce, Ge, Au, La, Li, Rb, Th, and Zr have been reported present, but sufficient quantitative data are not available, their nutritional significance is not established, and their toxicology has not been thoroughly investigated. It is also noted that although physiological significance has been ascribed to As, Al, Ba, Br, F, Ni, Rb, and Si, entirely satisfactory demonstration of their essential nature to higher animals has not yet been accomplished except possibly in the case of F.

**Molybdenum in the nutrition of the rat.** J. D. TERESI, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 137 (1942), No. 3, pp. 504-508).—The Mo determination carried out on the ashed samples involved the extraction of the orange thiocyanate complex with ether under conditions for maximum color development, followed by color measurement in an Evelyn colorimeter, making use of a special 470 m $\mu$  filter. Samples of cow's milk averaged 47.5  $\mu$ g. of Mo per liter (range 40-58  $\mu$ g.), while goat's milk averaged only 13.5  $\mu$ g. (range 11-16  $\mu$ g.). The Mo content of the body of rats was found to be low when the rats were fed goat's milk alone; when this milk was supplemented with Mo (as sodium molybdate) there was some increase in the rat content of this element, but the increase was so slight as to indicate very poor absorption of Mo by the rat. "About 0.5  $\mu$ g. of Mo per day was taken in by a growing rat on a basal ration of goat's milk mineralized with Cu, Fe, and Mn. Since supplementing this ration with Mo did not accelerate the growth rate, it

can be concluded that if Mo is needed by the growing rat, then 0.5  $\mu$ g. per day satisfies this requirement."

**The influence of aluminum sulfate and aluminum hydroxide upon the absorption of dietary phosphorus by the rat, H. R. STREET** (*Jour. Nutr.*, 24 (1942), No. 2, pp. 111-119).—The experiments described were designed to study the influence of aluminum on the utilization of phosphorus in growing rats as evidenced by their growth on a synthetic basal diet low in phosphorus (0.035-0.042 percent) but otherwise adequate, and variously supplemented with phosphate or with both phosphate and aluminum sulfate or hydroxide in definite atomic proportions of aluminum to phosphorus. When the aluminum was in the soluble form as aluminum sulfate and was fed in amounts chemically equivalent to the phosphorus in the ration, there was almost complete failure of growth, indicating that most of the phosphorus in the ration was rendered unavailable. Increasing the phosphorus to 0.60 percent so that the atomic ratio to aluminum was 5:2 permitted optimum growth, however, as judged by comparison with the growth responses of control rats receiving this level of phosphorus and no aluminum. On the other hand, when aluminum hydroxide was fed at levels representing 1:1, 2:3, or 2:1 atomic ratios with phosphorus, the growth response of these groups as compared with that of others on comparable phosphorus levels but without aluminum suggested that only one-third to one-fourth of the aluminum was converted to a form reacting with phosphorus.

**The effect of sulfaguandine on rat growth and plasma prothrombin, S. BLACK, R. S. OVERMAN, C. A. ELVEHJEM, and K. P. LINK.** (*Wis. Expt. Sta.*). (*Jour. Biol. Chem.*, 145 (1942), No. 1, pp. 137-143).—Sulfaguandine, an effective bacteriostatic agent for intestinal organisms, was used in a purified synthetic ration found adequate for growth and maintenance of a normal blood picture in rats. The sulfaguandine reduced the growth rate of the young rats, and this effect was accompanied by a state of hypoprothrombinemia as measured by the prothrombin time of a diluted blood plasma. The latter effect of the sulfaguandine was attributed to its inhibition of synthesis of vitamin K by the intestinal flora of the rat. *p*-Aminobenzoic acid and a distinct factor in liver extract (found in a norite eluate fraction) counteracted both effects of sulfaguandine. Vitamin K counteracted the prothrombin effect only. The mechanism of action of sulfaguandine and its antagonists in the rat is discussed, and the possible bearing of these findings on sulfonamide therapy is indicated.

**Studies on hemorrhagic anemia in dogs, J. M. McKIBBIN, A. E. SCHAEFER, C. A. ELVEHJEM, and E. B. HART.** (*Wis. Expt. Sta.*). (*Jour. Biol. Chem.*, 145 (1942), No. 1, pp. 107-122, fig. 1).—Adult dogs on a whole milk ration were rendered anemic by severe bleeding and were then observed for their blood regeneration response under the influence of various additions to the ration. They failed to respond to Fe and Cu when high levels of Co were added to the whole milk, but rapid regeneration occurred when this ration was further supplemented with whole dried liver or liver extracts. The activity of the liver was not wholly replaced by synthetic B vitamins, bile salts, cysteine, uropterin concentrates, and high levels of ferrous Fe when fed individually, but blood regeneration comparable to that produced by liver preparations was observed when the above supplements were fed together. Dogs receiving a highly purified ration (consisting of sucrose, casein, cottonseed oil, cod-liver oil, and a salt mixture), supplemented only with synthetic vitamins (thiamin, riboflavin, nicotinic acid, pyridoxin, pantothenic acid, and choline), retained their ability to regenerate a normal blood stream after severe bleeding for many months. This regeneration was complete in 2 weeks.

**Recent advances in our knowledge of the vitamins, C. A. ELVEHJEM.** (*Univ. Wis.*). (*Sci. Mo.*, 56 (1943), No. 2, pp. 99-104).—A brief survey.

**Vitamin, protein, calcium, iron, and calorie yield of vegetables per acre and per acre man-hour**, J. H. MACGILLIVRAY, C. G. HANNA, and P. A. MINGES. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 293-297).—Essentially noted from another source (E. S. R., 88, p. 546).

**The carotene content of sweet potatoes**, H. L. COCHRAN. (Ga. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 259-264).—This review article quotes data from the sources cited, and considers such phases as the effect of storage and of breeding on the carotene content and the stability of carotene and vitamin A in sweetpotatoes.

**Über eine neue Quelle des Karotins (Provitamin A) [A new source of carotene]**, L. J. GOMOLAKO (*Compt. Rend. (Dok.) Acad. Sci. U. S. S. R.*, n. ser., 32 (1941), No. 2, pp. 142-143).—Fruits of the golden currant (*Ribes aureum*), as grown in various European botanical gardens and including two seedlings grown from seed obtained from North America, were studied for their suitability as food and their chemical composition. Of the 15 samples investigated, 9 appeared satisfactory from the standpoint of flavor and odor, and these upon analysis gave the following range of values: Dry matter, 14.2-23.0 percent; ascorbic acid, 32.5-58.4 mg. percent; carotene 1.8-5.2 mg. percent; sugar, 5.5-12.9 percent; and acidity as malic, 0.9-1.5 percent. Corresponding values for a single sample of wild fruit, *R. aureum* [*diacanthum*] were 18.0, 21.1, 0.6, 12.0, and 1.1.

**The mobilization by alcohols of vitamin A from its stores in the tissues**, S. W. CLAUSEN, W. S. BAUM, A. B. MCCOORD, J. O. RYDEEN, and B. B. BREESE (*Jour. Nutr.*, 24 (1942), No. 1, pp. 1-14).—Earlier work on the mobilization of vitamin A from its stores in the tissues of dogs by ethyl alcohol (E. S. R., 84, p. 702) has been extended to methyl, propyl, and isopropyl alcohols with similar results, there being in all cases a marked increase in the vitamin A concentration in the blood serum whatever the mode of administration of the alcohol. The effect was attributed to the mobilization of the vitamin from its storage places, such as the liver and fat depots, rather than to increased absorption from the gastrointestinal tract. Nearly all of the mobilized vitamin A and the greater part of the vitamin in the tissues was found to be in the form of the ester but with a small portion of the free vitamin. It is suggested that vitamin A must be in the free form to be utilized by the tissues, but that it is stored as the ester.

**Tocopherol and the stability of carotene**, F. W. QUACKENBUSH, R. P. COX, and H. STEENROCK. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 145 (1942), No. 1, pp. 169-177).—Carotene supplements of 5  $\mu$ g. per day, fed in ethyl linolate, failed to produce growth in young rats deficient in vitamin A, but when fed in soybean oil or in the distillate obtained by molecular distillation of this oil growth resulted. The protective factor was apparently tocopherol, since equivalent amounts of synthetic  $\alpha$ -tocopherol and soybean tocopherol produced a similar response.  $\alpha$ -Tocopherol was effective at concentrations of 0.01-0.03 percent (2-6  $\mu$ g. daily). Vitamin K<sub>1</sub>, pyrogallol, catechol, and hydroquinone, also tested as substances that would inhibit the oxidative destruction of carotene, failed to promote growth when added at a level of 0.02 percent. Hydroquinone, however, gave a good response at 1 percent.  $\alpha$ -Tocopherol and hydroquinone, when tested in vitro, were equally effective antioxidants for carotene in linolate. Water extraction of the carotene-linolate solutions containing hydroquinone or tocopherol destroyed the effectiveness of hydroquinone but not of tocopherol. It is suggested that the low protective power of hydroquinone in the animal tests was probably due to its extraction from the lipid phase in the gastrointestinal tract. Hydroquinone was found to stabilize the tocopherol as well as the carotene in vitro, thus sparing the tocopherol for the protection of carotene in the tract. It is considered, in the light of these tests, that the problem

of instability of carotene in oil solutions exposed to oxygen can be solved by the use of lipophilic antioxidants such as tocopherols.

**The effect of dehydration upon the vitamin A content of eggs, S. M. HAUGE and F. P. ZSCHEILE.** (Ind. Expt. Sta.). (*Science*, 96 (1942), No. 2502, p. 536).—Paired lots of fresh, homogenized, liquid eggs and dried eggs collected at a commercial plant which employed a Mojonnier spray drier were saponified and extracted with ether and then subjected to spectroscopic examination. Determinations of absorption, made at 3,240 a. u. to indicate changes in vitamin A and at 4,370 a. u. to indicate changes in total carotenoid content, gave characteristic absorption curves of the fresh and dried eggs that were identical in the visible region and very similar in the ultraviolet. The drying process caused losses of carotenoid and vitamin A that were comparable to sampling errors and amounted to about 2 and 5 percent, respectively. Losses during storage of both liquid and dried eggs at  $-18^{\circ}$  C. for 14 weeks were no greater than those caused by drying. Biological assays of the homogenized and the dried eggs showed that little or no deterioration of the vitamin A took place in the dehydration, and that the samples on a moisture-free basis had vitamin A potencies of about 44 International Units per gram.

**Vitamin B complex content of beers, ales, and malt tonics, S. LAUFER, R. SCHWARZ, and L. LAUFER** (*Food Res.*, 7 (1942), No. 4, pp. 306-308).—Three different brands of beer, three of ale, and three of malt tonic, assayed by microbiological methods for various members of the B complex, were found to contain, respectively, per 100 cc. 1.47-4.02 (average 2.7), 1.11-8.19 (4.1), and 0.00-48.60 (18.6)  $\mu$ g. of thiamin; 22.7-33.0 (average 27.0), 30.4-38.0 (33.5), and 38.7-57.3 (48.4)  $\mu$ g. of riboflavin; 0.783-0.868 (average 0.817), 0.694-0.891 (0.817), and 1.040-1.790 (1.49) mg. of nicotinic acid; and 85-120 (average 102), 90-100 (94), and 100-133 (121)  $\mu$ g. of pantothenic acid. The low thiamin content is considered as probably due to absorption of thiamin by the yeast in the course of fermentation.

**Studies on the succinoxidase system of rat liver in riboflavin deficiency, A. E. AXELROD, K. F. SWINGLE, and C. A. ELVEHJEM.** (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 145 (1942), No. 1, pp. 297-307).—Determinations of succinoxidase in rat livers, by the modified method of Axelrod et al. with and without the addition of Al as  $AlCl_3$  to the flask, indicated that Al had no effect on the succinoxidase system either in the presence or absence of added Ca. Analyses of various components of the succinoxidase system of rat liver in riboflavin deficiency showed that the cytochrome oxidase component was present in large excess. Al and cytochrome oxidase were thus eliminated as factors of the succinoxidase system which might be affected in riboflavin deficiency and thus complicate the assay for succinic dehydrogenase. Cytochrome c and the enzyme systems involved in the destruction of coenzyme I were not diminished in riboflavin deficiency. The succinoxidase activity of rat livers per unit of dry weight, as measured by  $O_2$  consumption for the complete succinoxidase system, were increased in chronic starvation, while the total succinoxidase activity of the total liver was not affected. The succinoxidase activity of the rat liver was not diminished in biotin and pantothenic acid deficiency. The data presented in this and a previous experiment (E. S. R., 87, p. 894) indicated that one or more components of the succinoxidase system other than cytochrome c, cytochrome oxidase, Ca, or Al are diminished in riboflavin deficiency, and it was deduced from these results that the component or components affected in the riboflavin deficiency were flavoproteins.

**The thiamine and riboflavin contents of citrus fruits, M. I. BAILEY and A. W. THOMAS** (*Jour. Nutr.*, 24 (1942), No. 1, pp. 85-92).—The fruit samples

analyzed in this study were Florida-grown and represented one-fifth of the number of fruit in the standard box as purchased in New York City during the season of 1939-40. Analyses were carried out on the juice, expressed by pressure rather than by reaming and clarified by sedimentation. Thiamin was determined on the enzyme- (takadiastase) treated juice by a modification of the Hennessy and Cerecedo method (E. S. R., 82, p. 588). "In short, the thiamin was adsorbed on permutite, eluted with acidified potassium chloride solution, and oxidized to thiochrome by means of alkaline ferrieyanide solution. The thiochrome was extracted from the alkaline aqueous solution by isobutanol, and the intensity of its fluorescence measured in a Pfaltz and Bauer fluorophotometer, with prescribed 'blank' correction." Riboflavin was determined on the clear (filtered following sedimentation) juice by direct fluorometric measurement made on (1) the filtered juice, (2) the same with riboflavin additions (0.05 or 0.075  $\mu\text{g}$  per cubic centimeter), and (3) any two of the above treated with hydrosulfite for blank correction. From the several readings, the riboflavin content of the juice was calculated. The average values, expressed as micrograms per 100 cc. of juice, were obtained as follows for the thiamin and riboflavin contents, respectively: Pineapple oranges, 65 and 16; Valencia oranges, 70 and 15; seeded grapefruit, 35 and 12; seedless grapefruit, 32 and 11; tangerines, 69 (thiamin only). Based on the average juice volume of the particular specimens, the thiamin chloride hydrochloride content, expressed as micrograms per fruit, averaged 80, 91, 85, 81, and 45 for Pineapple and Valencia oranges, seeded and seedless grapefruit, and tangerines, respectively; the riboflavin per fruit was 20  $\mu\text{g}$ . per orange and 27  $\mu\text{g}$ . per grapefruit. The fruit sizes, designated as the number of individual fruits to just fill a standard Florida box, were 176, 70, and 150 for the oranges, grapefruit, and tangerines, respectively.

**The thiamin, riboflavin, nicotinic acid, and pantothenic acid contents of wild rice (*Zizania aquatica*), J. W. NELSON and L. S. PALMER. (Minn. Expt. Sta.). (*Cereal Chem.*, 19 (1942), No. 5, pp. 539-540).—The five samples of wild rice were of the native crop harvested by the Indians of Minnesota and were representative of the parched product processed and marketed by the Indians. The vitamin values, determined by methods noted, gave the following averages expressed as milligrams per 100 gm.: Thiamin 0.470, riboflavin 0.633, nicotinic acid 6.13, and pantothenic acid 1.01. These results indicate that parched wild rice may be regarded as a good source of these vitamins in human nutrition.**

**The thiamin content of wheat flour milled by the stone milling process, A. S. SCHULTZ, L. ATKIN, and C. N. FREY (*Cereal Chem.*, 19 (1942), No. 4, pp. 529-531).—White flours produced at the present time in two stone mills operating in the manner of the past century were assayed for thiamin content by the fermentation method modified to embody sulfite cleavage (E. S. R., 88, p. 293). Flours of the three millings, representing 54, 55, and 62 percent extraction, respectively, contained in this order 4.04, 4.74, and 4.52  $\mu\text{g}$ . of thiamin per gram as compared with 5.2, 4.67, and 5.6  $\mu\text{g}$ . per gram in the respective wheats; values for the respective brans were 5.82, 9.8, and 9.18  $\mu\text{g}$ . and for the middlings 6.27, 4.46, and 6.0  $\mu\text{g}$ . per gram. These stone-ground white flours contained, therefore, a concentration of thiamin roughly equivalent to that in the whole grain, and the offal or feed byproducts equaled or somewhat exceeded the flour in thiamin concentration.**

**The stability of vitamin B<sub>1</sub> in the manufacture of bread, A. S. SCHULTZ, L. ATKIN, and C. N. FREY (*Cereal Chem.*, 19 (1942), No. 4, pp. 532-538).—Thiamin was determined, by the yeast fermentation method which included the**

sulfite modification (E. S. R., 88, p. 293), in the dough batch after mixing and in the finished breads prepared as laboratory bakes based on the straight dough process. From each batch of dough, two loaves were baked at 410° F. for each of the following periods: 10, 20, 30, and 40 min. One loaf of each pair was prepared for total thiamin analysis, while the other was separated into crust, innermost crumb, and intermediate portion, each of which was analyzed separately. The investigation was carried out with enriched white bread made with a commercial enriching concentrate containing synthetic thiamin, a whole-wheat bread, and an enriched white bread made with high vitamin B<sub>1</sub> yeast. Determinations were also made on the dough and baked loaves of the three types of bread prepared and baked under normal commercial bakery conditions. The results of this study showed that there was a progressive decrease of thiamin as the time of baking increased, the destruction amounting to 3, 13, 21, and 33 percent in the increasing baking intervals employed; the loss in the well-baked loaf (30 min.) compared favorably with the 21-26 percent losses noted in the commercially baked loaves. The stability of the thiamin in baking was not affected by the source of the thiamin. The major part of the thiamin destruction occurred in the crust, in which the thiamin content was reduced by 50 percent as the time of baking was extended from 10 to 40 min.; in the same time the crumb lost only 17 percent of its thiamin. Results from the large-scale bakery experiments agreed with the laboratory results. The sulfite blank, which reflected the presence of interfering aminopyrimidine fermentation activity, was found to increase as thiamin was inactivated by increased baking time. This indicated that a portion of the thiamin was split as it was inactivated. The increase in sulfite blank was not equivalent to the thiamin destroyed, but equaled only 29 percent in the 40-min. bake.

**The effect of sodium bicarbonate on the thiamine content of peas,** H. J. DEUEL, JR., C. JOHNSTON, L. SCHAUER, and S. RAPAPORT (*Science*, 97 (1943), No. 2506, pp. 50-51).—Cooking tests were applied to fresh and frozen peas, the latter including those prepared by tunnel freezing (I) and others by plate freezing (II). In all tests 85 gm. of peas were cooked with 180 cc. of water; in sodium bicarbonate tests 0.22 gm. of NaHCO<sub>3</sub> was added. Thiamin determinations by the fermentation and bio-assay procedures indicated thiamin contents of 333, 408, and 351 µg. per 100 gm. of fresh peas and frozen peas I and II, respectively. These samples, when cooked in water 17, 6, and 6 min., respectively, retained per 100 gm. of fresh peas a total of 336, 416, and 340 µg. of thiamin (in peas and cooking water); soda reduced the cooking times to 8, 4, and 4 min., respectively, and gave thiamin retentions of 321, 374, and 218 µg. The greater loss of thiamin in type II of the frozen peas is attributed to the partial mashing of the peas by the method of freezing. Fresh peas (of another series) which were overcooked to the extent of rupture of the hulls averaged 35 and 57 percent of the original thiamin upon cooking in water, and in water and sodium bicarbonate, respectively. "The experiments indicate that no greater destruction occurs in the thiamin remaining in the intact pea after cooking with sodium bicarbonate than when water alone is employed. Slightly greater destruction results in the thiamin leached out of the pea during cooking. The loss only amounts to 8.3 percent in the frozen peas and 3.6 percent in the fresh peas cooked with sodium bicarbonate."

**The nicotinic acid content of meat,** W. J. DANN and P. HANDLER (*Jour. Nutr.*, 24 (1942), No. 2, pp. 153-158).—Data are reported on the nicotinic acid content of various cuts of meat purchased in local retail stores. The analyses were made by the chemical procedure of the authors (E. S. R., 87, p. 14), using completely decolorized digests of the tissue. Most of the cuts showed considerable variation from one sample to another, but there was no evidence that the various meats differed in nicotinic acid content. Thus, nicotinic acid, expressed

in micrograms per gram fresh weight, varied from 40 to 82  $\mu\text{g.}$  in beef muscle meats, from 54 to 102  $\mu\text{g.}$  in lamb muscle, from 49 to 91  $\mu\text{g.}$  in veal muscle, and from 61 to 80  $\mu\text{g.}$  in chicken leg muscle; the chicken breast muscle, however, was much richer, containing from 110 to 181  $\mu\text{g.}$  per gram. Kidney and liver were richer than the muscle meats in nicotinic acid, values obtained for these organs (from beef, pork, and veal) varying, respectively, from 65 to 100 and from 76 to 166  $\mu\text{g.}$  per gram fresh basis; chicken liver was equally rich, the samples analyzed varying from 114 to 178  $\mu\text{g.}$  per gram. It is pointed out that the values reported are considerably lower than those obtained by Waisman et al. (E. S. R., 84, 1, 563), employing bio-assay with the dog, and by McIntire et al. (E. S. R., 87, p. 150), using a chemical procedure with only partially decolorized digests, but that they corresponded more closely with results obtained by Waisman and Elvehjem (E. S. R., 86, p. 560) in microbiological assay and are believed to be more nearly correct. The effect of cooking was examined, using several types of meat; in general, from one-third to one-half of the nicotinic acid was lost, as calculated on the basis of the dry weight of the meat.

**The metabolism of pyruvate by liver from pantothenic acid- and biotin-deficient rats,** F. J. PILGRIM, A. E. AXELROD, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 145 (1942), No. 1, pp. 237-240).—The livers, homogenized in ice-cold Ringer-phosphate buffer solution, were permitted to act on the sodium salts of pyruvic, fumaric, and *l* (+)-lactic acids under specified conditions. Data on  $\text{O}_2$  consumption per milligram of dry weight of tissue per hour in the presence of the substrate, less the endogenous consumption, showed that there was a decreased rate of pyruvate oxidation in liver from the pantothenic acid- and biotin-deficient rats. These results are interpreted to indicate indirectly that these vitamins may be components of the enzyme systems concerned with the metabolism of pyruvate.

**Storage of pyridoxine in the rat,** L. R. CERECEDO and J. R. FOX (*Jour. Nutr.*, 24 (1942), No. 1, pp. 93-96).—Evidence along three lines is presented indicating that rats are capable of storing pyridoxin—(1) litters of rats of varying ages, which had been maintained on a satisfactory diet in which the B vitamins were furnished by 10  $\mu\text{g.}$  of thiamin chloride, 20  $\mu\text{g.}$  of riboflavin, and 0.3 cc. of a fuller's earth filtrate of pig liver extract equivalent to 3 gm. of fresh liver, were placed on a pyridoxin-free diet; (2) lactating rats and their litters were given a pyridoxin-free diet, beginning with the latter part of the lactation period; and (3) young rats, after a 5-, 10-, or 15-day period of depletion of all of the B vitamins, were given a pyridoxin-free diet plus graded doses of pyridoxin over a 10-day period, after which the supplement was discontinued. In all cases observations of growth and appearance of dermatitis showed a progressive increase in the rate of growth and corresponding delay in the onset of dermatitis correlated with the amount of the vitamin previously given. "These data suggest that the irregularity in the occurrence of dermatitis in rats deprived of pyridoxin (reported by several workers) may be ascribed, at least in part, to differences in the reserves of the vitamin present in the young animals at the beginning of the experiment."

**The effectiveness of linoleic, arachidonic, and linolenic acids in reproduction and lactation,** F. W. QUACKENBUSH, F. A. KUMMEROW, and H. STEENBOCK. (Wis. Expt. Sta.). (*Jour. Nutr.*, 24 (1942), No. 3, pp. 213-224).—Two basal diets were used—(1) the diet previously described by Schneider and Steenbock (E. S. R., 81, p. 884) in which the B vitamins were furnished by a rice bran concentrate very low in lipides supplemented by riboflavin and (2) the Burr and Burr diet (E. S. R., 63, p. 595) in which the source of the B vitamins was ether-extracted yeast. The first of these diets was much lower than the second in

unsaturated lipides, furnishing only 0.8 mg. calculated as linoleic acid per 10 gm. of food intake, as compared with 13 mg. for the second. Both diets were supplemented with 100  $\mu$ g. each of carotene and vitamin K<sub>1</sub>, 35  $\mu$ g. of calciferol, and 350  $\mu$ g. of tocopherol per rat per week. The experimental litters, with their mothers, were transferred from the stock diet at 12 days of age to a diet consisting largely of potatoes (E. S. R., 81, p. 600), weaned at a weight of 40 gm., and placed on one or the other of the two diets, with or without stated supplements of the fatty acids.

On both of the basal diets the rats were raised to maturity and bred, but after a prolonged gestation period and severe hemorrhage on parturition, the young were born dead or died soon after birth. When the diet was supplemented with fatty acids, growth was better on the rice bran than on the yeast diet. However, contrary to earlier observations of Schneider et al. (E. S. R., 84, p. 422) that rice bran concentrate can completely replace the essential acids, it was shown that it cannot prevent scalliness of the feet and tail. This scaly condition was observed on both basal diets after about 10 weeks and was prevented or cured by ethyl linolate and arachidonate but not by ethyl linolenate. Reproduction was also normal on the first two but not on the third supplement. Analysis of body fat showed a remarkable constancy in both the percentage of total fat and iodine values of the fat irrespective of the dietary supplements.

**Linoleic acid, pyridoxine, and pantothenic acid in rat dermatitis, F. W. QUACKENBUSH, H. STEENBOCK, F. A. KUMMEROW, and B. R. PLATZ, (Wis. Expt. Sta.).** (*Jour. Nutr.*, 24 (1942), No. 3, pp. 225-234).—This report, extending earlier studies (E. S. R., 84, p. 422), deals with the interrelationship of the factors involved in rat dermatitis as observed when the supplements were given as pure compounds added to a basal diet containing no more than 0.003 percent of unsaturated lipide calculated as linoleic acid and only thiamin and riboflavin of the B vitamins. The test supplements, administered by dropper (singly and combined in prophylactic and curative tests), consisted of synthetic pyridoxin hydrochloride and calcium *d*-pantothenate in aqueous solution and ethyl linolate prepared from corn oil. The system noted in an earlier paper (E. S. R., 81, p. 600) was followed in evaluating the skin condition.

The weanling rats on the basal diet developed severe acrodynia in from 4 to 5 weeks. "Pantothenic acid did not even alleviate the symptoms. Pyridoxin produced temporary alleviation but did not effect a cure. Ethyl linolate cured the acrodynia. Amounts of linolate which were subcurative alone became curative when given with pyridoxin. Pantothenic acid together with pyridoxin improved the dermal condition, and linolate subsequently produced further improvement. The three compounds together cured the acrodynia but did not cure completely the scaly condition of the tail and hind paws. The results indicate that an additional factor is involved. In prophylactic tests neither pantothenic acid nor pyridoxin prevented the acrodynia, but pyridoxin retarded the development of the dermal lesions. A lack of pyridoxin did not result in acrodynia when animals were fed both linoleic acid (corn oil) and pantothenic acid." These findings are compared with reports from other laboratories, and suggestions are given in explanation of such minor differences as have been found.

**Ascorbic acid content of some canned grapefruit juices prepared under various processing conditions, W. W. FLOYD and G. S. FRAPS. (Tex. Expt. Sta. et al.).** (*Food Res.*, 7 (1942), No. 5, pp. 382-387).—The samples of canned grapefruit juice, obtained with the cooperation of the leading citrus fruit canners of the Rio Grande Valley, were prepared under conditions of large-scale processing. Comparable samples representative of different commercial practices and samples of fresh, raw juice were analyzed for ascorbic acid by the dye titration method

according to a procedure outlined briefly. Twenty-one samples of fresh, raw juice from first-grade, tree-ripened grapefruit contained an average of 41.2 mg. ascorbic acid, with a minimum of 38.3 and a maximum of 46.4 mg. per 100 gm. The 109 samples of canned grapefruit juice averaged 33.7 mg. ascorbic acid (range, 26.3–39 mg.), this being 18.2 percent lower than the value for the fresh juice. Canned grapefruit juice that had been permitted to stand between extraction and processing for 3.5 or less, 5, 20, and 30 min. averaged, respectively, 38.5, 36.6, 29.0, and 26.9 mg. ascorbic acid per 100 gm.: these values, compared with the 41.2 mg. for fresh, raw juice, represented losses ranging from 6.6 to 34.7 percent. Canned juice from fruit containing approximately 90 percent of culls contained 29.5 mg. ascorbic acid as compared with 36.1 mg. in juices from fruit containing 10 percent or less of culls. Canned juice from fruit picked just after a February freeze averaged 31.1 mg. ascorbic acid per 100 gm., while canned juice from fruits that had been gathered in the same region just before the freeze contained 36.0 mg. per 100 gm. Juice prepared with machines using corrugated rollers or a rotary grater contained a little more ascorbic acid than that prepared by screen pressing or hand reaming.

**The vitamin C content of small fruits, R. A. LANEHERRY and L. BURKHART.** (N. C. Expt. Sta. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 41 (1942), pp. 198–200).—The berries were sampled and analyzed by the procedure described by the authors in a study of vitamin C and its sampling variation in strawberries (E. S. R., 88, p. 713). Blueberries contained much less ascorbic acid than did the strawberries, which had shown varietal averages ranging from 33 to 66 mg. per 100 gm., but, unlike the strawberries, did not show much varietal difference in ascorbic acid content. The ripe fruit of Cabot, Rancocas, Scammell, and Concord varieties of blueberries averaged, respectively, 18.6, 18.4, 16.5, and 16.0 mg. per 100 gm.; green Scammell blueberries contained only 3.3 mg. per 100 gm. Young, Boysen, and Lucretia varieties of dewberries averaged, respectively, 32.5, 25.9, and 27.0 mg. of ascorbic acid per 100 gm.; Dixie, Latham and Newburgh raspberries 32.5, 23.5, and 20.5, mg.; Early Wonder blackberry 23.5 mg.; and the Brainerd blackberry in the ripe and red stages, respectively, 12.9 and 11.6 mg. per 100 gm. of fruit.

**Vitamin C (ascorbic acid) content of the buffalo-berry, D. KNOWLES and I. WILK.** (N. Dak. Expt. Sta.). (*Science*, 97 (1943), No. 2506, p. 43).—Ascorbic acid was determined by the method of Morell (E. S. R., 87, p. 15) in the buffalo-berry, (*Lepargyrea* (= *Sepherdia*) *argentea*), a native fruit of North Dakota. The ripe fruit on the fresh basis contained over 150 mg. per 100 gm., and one sample picked on October 15, 1942, contained as much as 184 mg. Samples of buffaloberry jam contained from 80 to 90 mg. of the vitamin per 100 gm.

**Vitamin C content of persimmon leaves and fruits, C. G. VINSON and F. B. CROSS.** (Univ. Mo. and Okla. A. and M. Col.). (*Science*, 96 (1942), No. 2497, pp. 430–431).—Fresh green leaves from three wild persimmon trees and five named and cultivated varieties varied in ascorbic acid content, as determined by the dye titration method, from 2,030 to 3,280 mg. per 100 gm. Leaves recently dried in a Bussler oven varied from 2,550 to 4,150 mg. per 100 gm. (six samples), the green fruit (six samples) from 210 to 380 mg., and the ripe fruit (two samples) from 95 to 105 mg. per 100 gm. A tea made from the green or the dried leaves was found to be very acceptable after the addition of a little sugar. Tea made from the dried persimmon leaf contained about 60 percent of the titratable material originally in the leaf, but tea made from the green leaves contained only about one-third as much of the titratable material as did tea from the dried leaves. The titratable material in tea from tea leaves was only about 1 percent of the amount in the infusion from an equal weight of dried persimmon leaves.

**Rose-hip syrup: Vitamin C content and stability**, F. WOKES, E. H. JOHNSON, J. DUNCAN, J. G. ORGAN, and F. C. JACOBY (*Food*, 11 (1942), No. 131, pp. 212-213).—A brief general report of experience with rose hips and rose-hip syrups indicates that there were seasonal and regional variations in the ascorbic acid content of the rose hips and losses upon storage or drying of the hips or storage of the extract. Commercial syrups varied in potency and lost from 5 to 10 percent of their ascorbic acid per week when stored at 37° C., but only 1 percent at 5°. Tests with pure solutions of ascorbic acid indicated that increase in pH from 1 to 3.8 (about the lowest value for a palatable sirup) increased the rate of destruction of the ascorbic acid, and that the presence of sugar stabilized the vitamin against destruction. Storage of rose-hip sirup under nitrogen decreased but did not eliminate the destruction of the vitamin due to oxidation.

**Tomato catsup as a source of vitamin C**, W. B. ESSELEN, JR., and H. FRAM. (Mass. Expt. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 9, pp. 677-678).—Ascorbic acid was determined by the 2,6-dichlorophenolindophenol dye titration method in eight brands of catsup obtained in 14-oz. bottles, chiefly from local markets but some also directly from large catsup packers. The former samples were representative of those that had been handled under commercial conditions for from 9 to 12 mo., while the latter were fresh samples which had been packed only about 1 mo. Average figures for ascorbic acid in the several brands varied from 5.50 to 12.00 mg. per 100 gm., and the limited data indicated that there was a definite loss of ascorbic acid in the catsup stored for 1 yr.

**Loss of vitamin C during cooking of summer squash**, R. N. WOODRUFF and F. I. SCOULAR (*Food Res.*, 7 (1942), No. 4, pp. 267-271).—Two varieties of Texas-grown summer squash, White Patty Pan and Yellow Crookneck, contained, respectively, 29 and 30 mg. of ascorbic acid per 100 gm. when analyzed as garden-fresh samples and 23 and 22 mg. when analyzed after holding for 8 hr. in a local market. Holding under market conditions for as long as 4 days, as was done with the White Patty Pan variety, caused a reduction to 13 mg. per 100 gm. Cooking the squash cut in small pieces caused similar losses in the two varieties. Boiling for 10, 20, and 30 min. caused losses in these respective periods ranging from 39 to 43 percent, 49 to 57, and 53 to 62 percent in the various lots of garden-fresh or market-held samples. Boiling in salted water did not affect the size of the losses; boiling as whole, uncut squash rather than as diced or sliced samples resulted in somewhat smaller losses (42-45 percent) in the 20-min. period. Baking (White Patty Pan variety) for 20 min. following a 5-min. parboiling period effected greater losses than did boiling, from 65 to 67 percent of the ascorbic acid being lost if the squash was baked whole and from 70 to 73 percent if the sample was cut as for the preparation of stuffed squash. The greatest cooking losses (72 to 77 percent) resulted in samples diced or sliced, then boiled 3 min., and sautéed in fat for 10 min.

**A study of the ascorbic acid requirements of children of early school age**, V. M. and L. J. ROBERTS (*Jour. Nutr.*, 24 (1942), No. 1, pp. 25-39, figs. 3).—Two girls and three boys between the ages of 7 and 12 yr. living in a home for crippled and convalescent children served as subjects. The general plan of the study consisted in following the changes in blood levels and urinary excretion of ascorbic acid as the intake was increased at stated levels from an initial level of 15 mg. as furnished in the basal diet alone. There were eight experimental periods of 7 days each. The first week 40 mg. of ascorbic acid was given daily as a supplement to the basal diet, and this was increased by 20 mg. daily each week until the blood level remained practically constant with increased intake. The supplement was then gradually decreased until the 50-mg. level was reached for four subjects and 90 mg. for the fifth. At the end of each period a test dose

of 300 mg. of ascorbic acid was given to determine the state of tissue saturation. The requirements for the individual subjects were calculated according to several criteria, particularly the intake required to maintain average retention values, the intake to insure saturation as indicated by 50 percent excretion of a 300-mg. test dose, and the intake to maintain a blood level of 0.7 mg. or above. In this order the requirements ranged from 55 to 75, from 55 to 75, and from 55 to 65 mg. daily. By all three criteria, 65 mg. was the daily requirement of the two youngest and 75 mg. of the three oldest subjects. With other methods of interpretation the requirements varied from these amounts up to 125 mg., representing the intake to maintain maximum blood levels.

**Vitamin H, biotin, and coenzyme R: A brief review of the literature,** M. LANDY (*Chagrin Falls, Ohio: Res. Labs. S. M. A. Corp., 1941, pp. 13*).—A chronological review of the literature, with 58 references, to May 1941.

## TEXTILES AND CLOTHING

**Fabrics,** G. G. DENNY, edited by B. R. ANDREWS (*Chicago: J. B. Lippincott Co., [1942], 5. ed., rev., pp. XI+202, figs. [98]*).—This new and enlarged edition (E. S. R., 76, p. 283), giving definitions of fabrics and textile terms, records the progress and changes in textile products. The number of illustrations has been increased by one-third and many of the older ones have been replaced with new cuts. More attention than formerly is given to the importance of fibers, which are shown with photomicrographs and drawings, and special emphasis is placed on industrial fabrics. A brief section is devoted to the classification of fibers and to a representative list of trade terms for fabrics and finishes, with the names of manufacturers; textile tests and fiber analysis are considered; and Trade Practice Rules of the Federal Trade Commission are brought up to date.

**Fabrics for war,** S. M. SPENCER (*Textile Res., 12 (1942), No. 12, pp. 22-27, figs. 3*).—This brief summary points out some of the special applications for war needs of fabrics or treated fabrics such as Nylon, high tenacity rayon, and fabrics that are flameproofed, made water-repellent, waterproof, mildew-proof, or effective for concealment because of the satisfactory quality of the dyes. Most of the fabric treatments and coatings now proving so valuable in war are products of peacetime research.

**Quantitative analysis of linen in part linen fabrics,** W. KRAUSS (*Rayon Textile Mo., 23 (1942), Nos. 11, pp. 49-50, fig. 1; 12, pp. 53-54, fig. 1*).—Since the time required for the A. S. T. M. method of microscopic analysis for cotton-linen mixtures is too great for routine checks of part-linen fabrics, a new method is proposed which utilizes a larger sample than that used in the former method, thus eliminating lack of uniformity of the sample as a factor in the quantitative determination. According to this procedure, which is described in detail, a fabric sample of at least 2 by 2 in. or a yarn sample of 2-yd. length is used. From the fabric a number of yarns proportional to the thread count of the sample are pulled at random from each direction, the combined number of yarns from warp and filling totaling at least 20, and from the yarn sample twenty 2-in. lengths are cut at intervals. From each yarn or yarn section thus selected 1-mm. sections are cut to a total of about 1 in., and these small sections, properly assembled, are separated into individual fiber sections by shaking in a flask with about 75-100 cc. of distilled water. About  $\frac{1}{2}$  cc. of the well-shaken suspension is flooded onto a glass slide between the confines of two vertical lines drawn about 1 in. apart with a wax pencil; after drying uniformly the fibers are stained with Herzberg stain and covered with a 1-in. coverglass. After proper identification of the fibers on the slide, an actual counting of the fibers in the mixture is made at a magnification

of 200-250 diameters and with the use of a mechanical stage and a cross-hair ocular. The combined horizontal and vertical counts should total at least 1,000 fibers. The fiber diameter is determined on a total of about 100 fibers from the yarns (not the fiber suspension) mounted longitudinally in glycerol. The weight of the various fibers is calculated by multiplying the number of fibers by the square of their diameter and by their specific gravity, and from these figures percentages by weight can be calculated.

**Colorfastness of women's and children's wearing apparel fabrics, H. E. BORTON, M. BUTZ, P. B. K. MOORE, D. D. WILLIAMSON, I. LA BOSSIEL, B. BLACKMORE, B. KUSCHKE, and P. B. MACK.** (Pa., R. I., N. H., Md., N. J., and [N. Y.], Cornell Expt. Stas. and Pa. State Col.). (*Jour. Home Econ.*, 34 (1942), No. 8, pt 1, pp. 539-550, fig. 1).—The present report of the Northeastern Regional Experiment Station (Cooperative Textile Project (E. S. R., 81, p. 154), still in progress, is based on the findings of (1) laboratory tests of 1,000 colored fabrics and (2) inspections of worn-out garments in which 211 of these fabrics were observed for practical wearing performance in various women's and children's clothes. Of the 1,000 fabrics, 32.8 percent were cotton, 10.5 wool, 7.7 wool mixtures, 8.5 silk, 22.9 viscose, 2.2 acetate, 12.0 viscose and acetate, and 3.4 percent rayon mixtures other than those of viscose and acetate. The fabrics were rated by the series of tests for colorfastness recommended by the National Bureau of Standards for woven textile fabrics, as showing (1) no observable fading, (2) only slight fading, (3) some fading, and (4) severe fading. "All fabrics, regardless of fiber content, had an over-all average of 65.9 percent in the highest class of performance with respect to the following 10 colorfastness tests: Laundering (cotton), laundering (rayon), dry cleaning by the dry method, dry cleaning by the wet method, light, artificial acid perspiration, artificial alkaline perspiration, crocking dry, crocking wet, and pressing. The poorest average responses to the tests were found with the wet crocking and light tests. Other tests gave progressively better results in this order: Dry cleaning (wet); perspiration, alkaline; laundering (rayon); perspiration, acid; laundering (cotton); crocking (dry); pressing; dry cleaning (dry) (which showed the best response of any of the tests). The study clearly indicates the need for colorfastness standards for all types of wearing-apparel fabrics, with labeling to show the consumer the kind of colorfastness performance to be expected in a certain fabric."

The wearing apparel, for which the consumer records were entirely adequate, was returned for inspection to ascertain how closely the laboratory methods predicted the actual performance of the fabrics during wear. "Many of the tests failed to predict actual wear performance in any but a small percentage of the cases, the error being more frequently on the side of the test's being too mild than on the side of its being too rigorous. The need for more rigorous tolerances in applying the tests and in interpreting the results was indicated. In the case of the test for colorfastness to light, as an example, the method of conducting the test was satisfactory but a longer period of light exposure seemed desirable. In the case of the laundering test, a number of successive applications of the present test, or an accelerated one-wash test giving results equivalent to a multiple-washing test rather than the present use of one test, seems desirable if the test is to predict colorfastness of fabrics in consumer use, where repeated launderings are applied."

**Mildewproofing of military fabrics, C. W. HOCK and M. HARRIS** (*Rayon Textile Mo.*, 23 (1942), Nos. 11, p. 70; 12, pp. 47-48).—A greatly increased demand for mildew-proof fabrics for sandbags, camouflage cloth, and other materials has brought up many new production problems. The present status of the situation is outlined in the present report, which considers briefly the cause of mildew, re-

quirements for satisfactory mildew-proofing agents, compounds used for mildew-proofing, application of agents, toxicity, and tests for mildew-proofing. Laboratories carrying on investigations related to mildew-proofing are noted, and references to the literature on the subject are presented.

**How to sell and care for rayon and wool blended fabrics**, A. TEN Eyck (*Rayon Textile Mo.*, 23 (1942), No. 11, pp. 60-61).—It is recognized that neither merchant nor consumer has a great deal of information on spun rayon and wool blended fabrics, but that in the present wartime economy such information is needed to sell these fabrics to consumers "positively" and not as a substitute. This article, concerned with the properly constructed and finished blended fabrics, tells what they are, how well they will wear, and how to care for them. Valuable hints are given on washing, drying, pressing, dry cleaning, and stain removal.

**Analysis of 84 qualities of cotton dress prints**, M. M. HAYS and G. B. FRANKENBERG. (U. S. D. A.). (*Rayon Textile Mo.*, 23 (1942), Nos. 10, pp. 74-76, fig. 1; 11, p. 69).—This study was conducted cooperatively by the U. S. D. A. Bureau of Home Economics and the Farm Security Administration in the interest of assisting managers of cooperative association stores in the South to stock more satisfactory fabrics for purchase by Farm Security families. The fabrics, obtained from cooperative stores in several regions and from large retail and mail-order houses, were divided into four groups on the basis of their so-called gray counts (60 by 48 and lower, 64 by 60, 68 by 72, and 80 by 80) and were tested by standard procedures, which are noted briefly. The results, summarized and analyzed, indicated that finishing increased the warp count and decreased the filling count, although the total number of warp and filling yarns remained approximately the same. The grab breaking values were in general directly related to the count, although there were several fabrics in each group that had approximately the same strength. The grab values for breaking strength were usually higher than those obtained by the strip method, but the values by the two methods were correlated. The loss of weight on desizing decreased in general as the count increased, although there was some overlapping, and varied from 6.0 to 30.0 percent in the 60 by 48 and lower fabrics to from 1.5 to 8.9 in type 180 fabrics; 7 out of 43 of this latter type had finishing losses of 3 percent or less. Poor colorfastness to light was characteristic of many of the fabrics, only 27 of the 84 rating class 3 or higher (i. e., expected to give satisfactory performance when good fastness to light is essential). As a group, however, the fabrics showed excellent colorfastness to washing. The information given on the labels on the fabrics was the only guide available to the purchasers. It showed count in only 12 cases and colorfastness in somewhat more, but often in a misleading way, since no distinction was made between colorfastness to light and to washing, and since the statements were not always borne out by the tests.

Additional information is being gathered from consumer service tests on these fabrics to serve as a basis for setting minimum specifications for dress prints to be sold in F. S. A. stores. Tentatively, it is proposed that dress fabrics should classify 3 or higher to light and also to washing, and that warp breaking strength by the grab method should be not less than 38, 40, and 42 lb. for prints of types 124, 140, and 160, respectively; for the filling direction the minimum should be 20, 28, and 30 lb. The minimum weight per square yard should be 2.4, 2.6, and 2.8 oz. for the three types.

**Development of soybean fiber by Ford**, L. STOFFER (*Rayon Textile Mo.*, 23 (1942), No. 11, pp. 45-48, figs. 6).—"Output of the synthetic fiber—the first successful textile filament to be derived from a vegetable protein source—is already around 1,000 lb. a day in the pilot plant, which has been in operation since early 1941, and will reach 5,000 lb. a day in the new plant." The bulk of

this present and future output is going into textile products for the armed services. The process of fiber production consists essentially in extraction of the protein from the dried oil-free meal by a weakly alkaline solvent such as 0.1 percent sodium sulfite solution, clarification of the solution, and precipitation of the protein with an acid, the resulting curd being washed and dried. The protein is then dissolved by a special process to give a viscous solution containing 20 percent protein. This solution is forced through spinnerettes, containing from 500 to 5,000 apertures in a surface  $1\frac{1}{2}$  in. in diameter, into an acid bath which coagulates the tiny filaments. These are stretched as they are pulled through the bath, and as they emerge they are gathered together and combined into a single yarn. The fiber may be wound on a reel and can then be bleached and dried if desired. The fiber is removed from the reels in skein form to be cut to any staple length desired. The fiber is white to light tan in color, with medium luster; is nearly circular and has little pigmentation; has sp. gr. 1.31 measured in water; has a warm soft feel, a natural crimp that imparts a high degree of resiliency, and a strength well above 80 percent of that of virgin wool; and is very resistant to the action of mold.

**Substitutes for jute and manila fibers**, A. C. WHITFORD (*Textile Res.*, 12 (1942), No. 12, pp. 2-7, figs. 3).—Four types of fibers that have found satisfactory use for a long time, are known to have very desirable qualities, and are adapted to production in the United States are suggested as the best substitutes for jute and manila fibers. These four are *Sansevieria* (*S. zeylanica* and *S. guineensis* (= *thyrsiflora*), known as bowstring hemp and Guinea bowstring hemp), *Hibiscus esculentus* (okra), *H. cannabinus*, and *Urena lobata* known as Caesar weed or French cocklebur. The first two are coarse rope fibers and the latter two finer jutelike materials. These plants are discussed with regard to ease of production, yield, time required before production can begin, and adaptability to replace manila and jute.

**Wearing qualities of similar brands of silk and Nylon hose compared**, G. M. SMITH and H. M. FLETCHER. (Kans. Expt. Sta.). (*Rayon Textile Mo.*, 23 (1942), Nos. 11, pp. 75-76; 12, pp. 62-63, 64).—Four popular brands of hosiery, including a total of 22 pairs of silk and 17 pairs of Nylon hose, were represented in this study in which 1 pair of silk and 1 of Nylon of each brand were used as controls, while the others were subjected to actual wear tests, all hose of one brand being worn by a single person for whom the hose were chosen for size and leg length. Data concerning the physical characteristics of the hose, the results of bursting tests on the control and the worn hose, and wear and fading results with the latter are presented and discussed. Statistical analysis of the data to determine the significance of the differences between silk and Nylon hose showed that the Nylon hose—control and worn—were superior to the silk in bursting strength at the knee and in the leg. The silk and Nylon controls were not significantly different as to bursting strengths of heel, ankle, and welt, but the toe of the silk controls was stronger than that of the Nylon. With wear, however, more holes were worn in the toes and heels of silk hose than in the Nylon. Most of the failures in both types of hose were due to snags that developed into runs. The number of hours of service for the Nylon averaged 448.59 and for the silk, 156.74. The Nylon faded more than the silk, due probably to the greater length of time worn and the greater number of times laundered. The silk hose were laundered an average of 12.2 times and the Nylon 33.5 times. Under these conditions and using a 15-hr. day as the basis, the silk hose cost 9.9 ct. per day and the Nylon 4.5 ct. Although the initial cost of the Nylon—\$1.35 a pair—was greater, they wore so much longer that the cost was about half that of the silk hose, which initially cost from \$1 to \$1.15 a pair.

**Mending men's suits**, C. L. SCOTT and A. F. HAGOOD (*U. S. Dept. Agr., Misc. Pub.* 482 (1943), pp. 24, figs. 31).—This publication describes and illustrates ways to strengthen for longer wear, to repair, to alter, and to care for men's suits and overcoats.

### MISCELLANEOUS

**The use of tests of significance in an agricultural experiment station**, G. W. SNEDECOR. (Iowa State Col.). (*Jour. Amer. Statis. Assoc.*, 37 (1942), No. 219, pp. 383-386).—An appeal to express tests of significance of experiments in terms of probability.

**Wartime service for Arkansas agriculture: Fifty-fourth Annual Report [of Arkansas Station, 1942]**, W. R. HOBLEACHER (*Arkansas Sta. Bul.* 428 (1942), pp. 55, figs. 6).<sup>4</sup>

**Science serving agriculture: Biennial Report [of Oklahoma Station, 1941-42]**, I, II, W. L. BLIZZARD and L. E. HAWKINS (*Oklahoma Sta. Bien. Rpt.* 1941-42, pls. 1, pp. 92, figs. 45; 2, pp. 23).<sup>4</sup>

**Colorado Farm Bulletin, [October-December 1942]** (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 4, pp. 15, figs. 5).—In addition to several articles noted elsewhere in this issue, this number contains the following: Problems Born of War Present Challenge to Experiment Station; Program Revised (pp. 6-8); Bulk Storage of Potatoes To Save Burlap Costs No More, Former Study Shows, R. T. Burdick (pp. 9-10); and Lime Has Importance in Feedlot Ration, in Sanitation, and in Treatment of Manure (pp. 13-15).

**Publications available from the [Kansas] Agricultural Experiment Station** (*Kansas Sta. Cir.* 211 (1942), pp. [4]).—The available bulletins and circulars, classified under agricultural economics, agricultural production, and home economics, are listed.

**Notas sobre el progreso de la agricultura y las industrias agropecuarias de Tucuman durante los ultimos sesenta años [Progress of agriculture and animal industry in Tucumán during the last 60 years]**, W. E. CROSS (*Bol. Estac. Eapt. Agr. Tucumán*, No. 36 (1942), pp. 75, figs. 11).—Progress since 1882 is reviewed under the headings of factors of progress, including an account of the agricultural experiment station at Tucumán; the sugar industry; and general agriculture.

**New conditions and the agricultural industry: Report of the Department of Agriculture and Forestry and Food Control Organization for the year ended 31 August, 1942**, P. R. VILJOEN (*Farming in So. Africa*, 18 (1943), No. 202, pp. 64, figs. 8).

<sup>4</sup> The experimental work not previously referred to is for the most part noted elsewhere in this issue.

## NOTES

**Florida Station.**—Ralph L. Smith, assistant agronomist of the South Carolina Edisto Substation, has been appointed associate agronomist in charge of Mobile Unit No. 2 of the North Florida Substation, with headquarters at Milton. Mobile Units, working directly with growers as provided for by the State Legislature in 1941, were set up "for the purpose of study and research in growing, development, and demonstration of peanuts, velvetbeans, sweetpotatoes, corn, cotton, pasturage, and forage crops."

**Georgia Station.**—Dehydration equipment in the station laboratories is being used regularly by vocational agriculture teachers and others to gain information useful in running community dehydration plants.

Recent appointments include Dr. E. S. Luttrell as associate botanist and H. G. Baker as associate agronomist, replacing Dr. Kenneth H. Garren and S. V. Stacy, who are now in the Army, and O. L. Brooks as agronomist at the Mountain Substation vice J. C. Mercer, recently resigned to join the U. S. D. A. Soil Conservation Service. Dr. F. F. Cowart, a former associate horticulturist, has returned to the station.

**Kansas College and Station.**—Waxy Club, a cross between Leoti Red and Club Kafir, has been released for commercial production as a replacement source of starch for tapioca and other tropical roots. This variety is apparently free from an objectionable water-free pigment found in starches obtained from other sorghum varieties.

According to a note in *Kansas Industrialist*, Dr. Earl B. Working, professor of the milling industry, has resigned to accept a position as director of chemical research with the Haitian-American Society for Agricultural Development and will carry on studies in the production of rubber from *Cryptostegia*. Frank S. Burson has resigned as extension instructor in agricultural economics.

**Louisiana Station.**—Clarence W. Dubois has been appointed research associate in food preservation and will direct investigations with special reference to quick freezing.

**Massachusetts College and Station.**—Frank A. Waugh, emeritus professor of landscape architecture, died on March 20 in New York City. Born in Sheboygan, Wis., on July 8, 1869, he received from the Kansas College the B. S. degree in 1891 and the M. S. degree in 1893. He had also been a student in Cornell University and the horticultural schools in Germany and France. He was assistant horticulturist in the Kansas College in 1891, professor of horticulture and horticulturist in the Oklahoma College and Station from 1892 to 1895 and the Vermont University and Station from 1895 to 1902. Coming to Massachusetts in the latter year as head of the department of horticulture, he greatly enlarged its activities, especially in what was then the relatively pioneer field of landscape engineering. From 1932 to his retirement in 1939 he had been professor and head of the department of landscape architecture. He exercised a wide influence by the training of men in this field and also as the author of many textbooks and other writings in pomology, landscape gardening, and rural improvement.

**Montana College and Station.**—O. A. Parsons, associate professor and assistant in agricultural economics, has been given leave of absence for military service.

**New Mexico College and Station.**—J. O. Bridges, associate professor of animal husbandry and associate animal husbandman, has resigned to engage in livestock production and farming in Idaho.

**Cornell University.**—John H. Barron, extension professor of field crops, retired on March 1 following 32 years of service in extension work.

**New York State Station.**—Simple and practical methods for comparing the merits of different detergents and cleaning compounds used by food processors, milk plants, farmers who are dispensing fruit and vegetable juices, and others concerned with the cleaning and sterilizing of food processing equipment have been worked out at the station. Processors of fruit and vegetable juices are finding these studies are also helpful in cleaning and sterilizing the glass containers returned by patrons.

Dr. Donald K. Tressler, who has headed the work of the chemistry division at the State station here since 1933, has entered the employ of the General Electric Company. His new work will have to do chiefly with the research program at the Bridgeport, Conn., laboratories of the company, with particular reference to refrigeration and the freezing preservation of foods.

Walter D. Enzie has resigned as assistant professor of vegetable crops to continue vegetable crop breeding and variety testing for the Snider Packing Corporation in Albion, N. Y. Thressa Campbell, investigator in bacteriology, has accepted a position in the department of fruit products in the California Station and has been succeeded by Robert C. Thomas.

**North Dakota College and Station.**—Dr. John C. McDowell, assistant professor of agriculture in 1903-4 and professor of agriculture in 1905-8 and subsequently associated with the U. S. Department of Agriculture until his retirement in 1937, died in Washington, D. C., March 31 at the age of 75 years. A native of Wisconsin and a graduate of the University of Wisconsin in 1903, he received from American University the A. M. degree in 1925 and the Ph. D. degree in 1927. His early work with the Department was in the field of farm management, and from 1916 he was associated with the Bureau of Dairy Industry as senior animal husbandman and chief of its dairy herd improvement investigations. He was the author of several books, including a Boy Scout Handbook on Dairy Farming.

**Clemson College.**—H. H. Willis, dean of the textile school, has resigned, and R. K. Eaton, professor of carding and spinning, has been appointed acting dean.

**Wyoming Station.**—A new Adams project has been approved on postparturient mortality of Wyoming range cows. It is hoped the causative factor or factors involved in these losses and a method of preventing or controlling them may be determined. A thorough study of the symptoms and pathology of the disease will be made, as well as the value of therapeutic measures. The work will be carried on by the departments of animal production and veterinary science, with blood analyses by the department of research chemistry.

**Inter-American Institute of Agricultural Sciences.**—The formal dedication of this institute (E. S. R., 88, p. 576) took place on March 19. The principal speaker was Vice President Henry A. Wallace, then on his tour of Central and South America. In his address Mr. Wallace visualized the institute as a focal point of research in the field of tropical agriculture, drawing students and investigators from all sections of the Western Hemisphere.

Announcement has been made that despite the scarcity of building materials the institute will be completed in 1943.

## INDEX OF SUBJECTS

---

**NOTE**—The abbreviations "Ala.", "Conn. [New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R.U." to those of the experiment stations in Hawaii and Puerto Rico (University station); and "U.S.D.A." to those of this Department.

---

- AAA pasture allowances under new program, Miss. 186.
- Abacá fiber industry, establishment in Central America, U.S.D.A. 617.
- Abattoir, Baton Rouge, relation to retail meat supply and production and marketing problems, La. 122.
- Abortion, *see* Bang's disease and *Brucella abortus*.
- Acacia berlandieri*, toxicity, feeding tests to determine, Tex. 99.
- Acanthoscelides obtectus*, *see* Bean weevil.
- Accidents, prevention on farms and in homes, U.S.D.A. 267.
- Accounting, farm, *see* Farm accounts.
- Acetic acid and glucose as nutrient in feeds, comparison, 90.
- Acetic acid, enzymatic formation from acetoacetic acid, 583.
- Acetoacetic acid, acid-splitting reaction of, 583.
- Acetobacter suboxydans*, growth factor for, 740.
- Achondroplasia, recessive, new type in cattle, 611.
- Achras sapota* response in latex yield to wounding by ibidem method of tapping, 463.
- Achromobacter harveyi*, studies, 457.
- Achromotrichia, nutritional, in rats, 139.
- Acids—  
    amino, *see* Amino acids.  
    fatty, *see* Fatty acids.
- Acorns, cause of olive-colored yolks, 519.
- Aorobasis caryae*, *see* Pecan nut casebearer.
- Acrylonitrile, toxicity against confused flour beetle, 505.
- Actenodes* spp., revision, U.S.D.A. 228.
- Actinobacillosis and actinomycosis, diagnosis, 679.
- Actinomycetes**—  
    *antibioticus*, chemical nature of actinomycin produced by, 580.  
    *viridochromogenus*, thiamin production by, 458.
- Actinomycetes**—  
    antagonistic, distribution in nature, 451.  
    bacteriostatic and bacteriolytic properties, 600.  
    colony variation under constant conditions, 19.  
    in inland lakes, 310.  
    soil, medium for rapid cultivation, 305.  
    Actinomycin A isolated from *Actinomyces antibioticus*, chemical nature, 580.  
    Actinomycosis and actinobacillosis, diagnosis, 679.
- Adelphocoris**—  
    *rapidus*, *see* Plant bug, rapid.  
    *superbus* on cotton, control by dusts, 504.  
    *superbus* studies, Tex. 73.
- Adhesive for plywood, cottonseed protein for, Miss. 154.
- Adrenals, assay for lactogenic hormone, 754.
- Acrobacter**—  
    *aerogenes* associated with slime, disinfectants for, relative toxicity, 154.  
    spp. in factory-packed ice cream, 96.
- Aerobiology, treatise, 444.
- Agar, reclaiming for bacteriological use, 26.
- Agar recovery, simple procedure for, 600.
- Agranulocytosis in rats, prevention and treatment, 526.
- Agrarian conflicts in New York and the American Revolution, 697.
- Agricultural**—  
    adjustments—  
        for Chase Co. and area analysis, Kans. 537.  
        in Nemaha Co. and area analysis, Kans. 397.  
    colleges, *see* specific colleges.  
    committees, British county war, U.S.D.A. 540.  
    cooperation, trends in, 536, 693.  
    credit—  
        agencies in a cotton county, Tenn. 120.  
        in Canada, U.S.D.A. 265.

## Agricultural Continued.

## credit—continued.

in cotton type-of-farming areas,  
Tenn. 120.

in Denmark, U.S.D.A. 265.

in Germany, U.S.D.A. 265.

principles and practice, 264.

engineering, *see* Engineering.

## equipment—

conservation in wartime, Mich. 827.

program, Nation-wide, 831.

experiment stations, *see* Experiment  
stations.

extension, *see* Extension.

finance, principles and practice of farm  
credit, 264.

income and export market, 1910 1940,  
693.

industry in South Africa and new con-  
ditions, 867.

journals, new, 430.

labor, *see* Farm Labor and Labor.

land use program for State, development,  
Kans. 693.

## machinery—

and equipment, estimating needs,  
690.

and equipment, studies, U.S.D.A.  
827.

duty of, 690.

gearing to war effort, 256.

in Britain's food production effort,  
107, 832.

rationing of, 831.

rental rates for, 831.

rubber-tired equipment of, U.S.D.A.  
108.

suitable for southern farms, 256.

wartime allocation, 830.

wartime distribution in United  
Kingdom, U.S.D.A. 124.

Marketing Administration, report, U.S.  
D.A. 841.

output control in wartime, 536.

policy, schisms in, shift toward human  
welfare, 393.

price policies in wartime, 393, 536.

prices, bases for control, 692.

problem of Venezuela, U.S.D.A. 123.

## production—

and nonagricultural employment in  
Rhode Island, R.I. 263.

expanded, Bolivian progress toward,  
U.S.D.A. 696.

expansion, obstacles to, 393.

goals, Miss. 537.

goals in 1942 and establishing those  
for 1943, U.S.D.A. 835.

in 1943, forecast of changes in,  
Calif. 836.

problems, wartime, station research  
applied to, 722.

## products—

marketing, *see* Marketing.

prices in Iowa, Iowa 124.

prices, indexes of prices and pur-  
chasing power, Okla. 261.

## Agricultural—Continued.

relations with Mexico, U.S.D.A. 540.

research—*see also* Research.

dividends from investment of funds  
in, Utah 720.

in wartime, value, Mont. 719.

residues, plastics from, U.S.D.A. 723.

resources of Australia, U.S.D.A. 839.

resources of Madagascar, U.S.D.A. 405.

resources of Mozambique, U.S.D.A. 405.

sciences, Inter-American Institute of,  
576, 869.

situation and tables on prices, Okla. 693.

statistics, developments in sampling for,  
270.

Statistics, proposal for revision, 393.

surpluses, disposal of, 393.

tenancy, *see* Farm tenancy, Farm tenure,  
and Land tenure.

## Agriculture—

and conservation, papers on, 287.

as commercial industry comparable to  
other branches of economy, 393.

changes in Arkansas, insect problems re-  
sulting from, 362.

climatology in service of, U.S.D.A. 298.

Department of, *see* United States De-  
partment of Agriculture.

effects of American-Canadian trade reci-  
procity on, 693.

electricity in, *see* Electric.

in Australia and war effort, U.S.D.A.  
840.

in Colombia, U.S.D.A. 840.

in Cumberland Co., significant changes  
in, Tenn. 262.

in Kentucky, trends, Ky. 838.

in 1917-18, price administration, pri-  
orities, and conservation of supplies

affecting, U.S.D.A. 400.

in the Americas, U.S.D.A. 768.

in Tucumán during last 60 years, prog-  
ress, 867.

in Yakima Valley, economic conditions  
and problems, Wash. 262.

mathematics in, 272.

of West, effect of post-war reclamation  
expansion, 536.

permanent, textbook, 271.

rescue programs and managed agricul-  
tural progress, 393.

scale of operations in, 393.

scale of operations in, comment on and  
rejoinder, 693.

second Inter-American Conference of,  
U.S.D.A. 124.

social economics of, 405.

special research in, U.S.D.A. 723.

trends in Providence and Bristol Coun-  
ties, R.I. 394, 397.

victory program of, relation to drain-  
age, 107.

vocational, and the fieldman, 520.

vocational, supervised practice in, Iowa  
125.

war program in, engineering contribu-  
tion to, 252.

## Agriculture—Continued.

wartime, problems in planning, 536.  
western, in wartime and after, papers  
on, 536.

*Agrius arcuatus torquatus*, notes, 219.

*Agriotes obscurus*, biology, 654.

*Agriotes sputator*, biology, 654.

*Agrobacterium tumefaciens* n.g. and n.comb.,  
proposed name, 457.

*Agrotis orthogonia*, see Cutworm, pale west-  
ern.

Aircraft decay, U.S.D.A. 640.

Airplane wood from Sitka spruce, importance  
of fungi and defects in handling, 780.

*Alabama argillacea*, see Cotton leafworm.

Alaska Stations report, 719.

Albinism in Virginia deer, 472.

## Albumin—

alkali-treated bovine serum, administra-  
tion to man and animals, effect, 241.

egg, injury in man, cure with biotin,  
418, 711.

egg, injury in rats, cure by avidin, 283.

egg, ovomucin gel of, characteristics,  
805.

*Alcaligenes* genus—

difficulties in defining, 599.

validity, 457.

Alcohol from citrus-waste liquors, U.S.D.A.  
723.

Ale, vitamin B complex in, 856.

## Alfalfa—

and bromegrass mixture, continuous v.  
rotation grazing with ewes and lambs,  
187.

and bromegrass pastures, sheep grazing  
methods, Nebr. 42.

bacterial wilt and virus dwarf, 343.

biological value for dairy helpers, 90.

boron fertilization, 758.

breeding, Kans. 618, Nebr. 41, U.S.D.A.  
616.

culture tests, Mont. 619.

effect of cutting systems on, [Conn.]  
Storrs 758.

efficiency of phosphate fertilizers on  
calcareous soil for, 758.

fertilizer requirements, N.H. 188.

fertilizer tests, Okla. 756, R.I. 326.

for detecting boron deficiency in soil,  
U.S.D.A. 504.

for fattening sheep, 375.

for green manure, Utah 186.

for pasture and hay, seeding practices,  
and seeds, N.J. 187.

grazing studies, Mont. 619.

ground, for brood sows, Mich 668.

hay, availability of carotene compared  
with carotene in oil, 90.

hay, barn curing experiments, Ohio 392.

hay, nutritive value, 93.

hay, vitamin A and D potency, 90.

inoculating with pure cultures of legume  
nodule organism in Argentina, 312.

insects, Kans. 655.

leafhopper control by delayed cutting,  
N.C. 473.

## Alfalfa—Continued.

meal in turkey rations, Utah 670.

meals, carotene content, Mass. 798.

nitrogen utilization in young sheep, effect  
of cystine supplementation, 234.

nurseries, uniform, U.S.D.A. 474.

pasture, effect on beef cattle, Nebr. 84.

pasturing with hogs, Nebr. 41.

plant pigments, use of, U.S.D.A. 723.

production, B as essential for, N.C. 473.

root- and crown-rotting fungi in Alberta,  
varietal resistance, 349.

rust resistance of species and varieties,  
487.

seed, legume bugs in, insecticidal con-  
trol, 365.

seed, *Lygus* bugs in, insecticidal tests for,  
787.

seed production, Oreg. 619.

seed production, effect of boron, 620.

silage, see Silage.

stem nematode, 343.

studies, Kans. 618.

superior varieties or strains grown by  
station, Oreg. 619.

varieties, determining hay yields, 759.

varieties, yield and winter injury, Pa.  
619.

variety tests, Alaska 617, Kans. 618,  
Nebr. 41, Tex. 42.

vitamin A and carotene values, U.S.D.A.  
670.

weevil studies, Oreg. 655.

white root rot control, 343.

wilt-resistant variety, A-136, U.S.D.A.  
616.

wilt-resistant variety, new, Utah 620.

yellow-flowered, hardiness, growth habit,  
and seed production, Alaska 617.

yellow, effect of borax and potash, Tenn.  
772.

Algae of British soils, ecological and taxo-  
nomic study, 602.

Algae, photosynthesis of, 316.

Alkaline soils, loss of ammonia from am-  
monium sulfate applied to, 597.

*Allendecsalazaria*, systematics of, 659.

*Allodermomyssus sanguineus*, annoying to  
man, 796.

*Allotropa utilis*, parasite of apple mealybug,  
223.

*Alternaria*—

early blight of tomatoes, breeding for  
resistance to, Tex. 59.

fungus and new mite on citrus, 230.

*passiflorae* control, 216.

*tenuis*, cause of sunflower leaf spot, 211.

## Alyceclover—

fertilizer tests, Ga. 617.

production test, Ga.Coastal Plain, 325.

tests, Miss. 186.

*Amauronematus ascalae* in greenhouse at  
Collingale, 664.

Amazon fly, Sao Paulo strain, liberations and  
shipments to Louisiana, P.R. 655.

*Amblyomma gertschi* n.sp., notes, 512.

- Ambrosia beetles** on fruit trees in California, 362.
- Ambrosia trifida**, sex expression in, effect of photoperiod, 32.
- Ambush bug**, economic status, appraisal. 75.
- American**—
- Dairy Science Association, student chapter, 808.
  - Phytopathological Society, Pacific division, meeting, 58.
  - Scientific Congress proceedings, 287.
- Amino acids**—
- aromatic sulfonic acids as reagents for, 581.
  - contribution to normal nutrition, 277.
  - effect of light on, N.Y.State 149.
  - free, carboxyl groups in gasometric determination, 588.
  - free, determination by titration of carbon dioxide, 588.
  - in hemoglobin formation, 704.
  - reactions studied by methods of non-aqueous titrimetry, 729.
- p-Aminobenzoic acid**—
- growth factor for *Acetobacter suboxydans*, 740.
  - role in reproduction and lactation in rat, 420.
- Ammonia**—
- conductometric determination, 729.
  - in desert soils, microbiological oxidation, Ariz. 451.
- Ammonium sulfate** applied to alkaline soils, loss of ammonia from, 597.
- Amoeba**, unidentified, parasite of squirrel, 497.
- Amperometric titrations**, 290.
- Amphimallon majalis**, importance and control, N.Y.State 785.
- Amphorophora**—
- osborni* n.sp., description, 366.
  - ribiella*, new aphid associated with, on black currant, 366.
- Amplex compressa**, biological notes, 74.
- Anabaena cylindrica**, N fixation by, 312.
- Anabrus simplex**, see Cricket, Mormon.
- Anaerobic**—
- bacilli, flagella staining, 309.
  - species, facultatively anaerobic, metabolism of, 457.
- Anagrus epos**, effect of dormant sprays on, 510.
- Analysis**, qualitative semimicro, Barber pressure bulb method, 586.
- Analytical methods**, referee's reports, 585.
- Ananas** genus, taxonomic study, 25.
- Anaplasma**—
- marginale*, transmission experiments with biting flies, 217.
  - nature of, 99.
- Anaplasmosis**—
- carriers of, Okla. 783.
  - cases, occurrence of *Bartonella* in, 384.
  - in cattle, Tex. 99, U.S.D.A. 98.
  - of cow, fowl tick as vector, 826.
  - studies, U.S.D.A. 676, Kans. 676.
- Anasa tristis**, see Squash bug.
- Anastrepha**—
- ludens*, see Fruitfly, Mexican.
  - new species and notes, 662.
- Ancylis comptana fragariae**, see Strawberry leaf roller.
- Ancylostoma caninum**, anthelmintic efficiency of Ficin against, 247.
- Androgen**—
- assay by the chick comb method, technic, 184.
  - ovarian, source of, in mice. 472.
  - treatment of castrated female rats, mating behavior in, 752.
- Androgenic activity**, variables affecting estimation, 183.
- Anemia**—
- equine infectious, U.S.D.A. 97.
  - hemorrhagic, in dogs, 854.
  - hypochromic, relation to multiple dietary deficiencies, 277.
  - in chicks, Mo. 84.
  - infectious, U.S.D.A. 676.
  - infectious, equine, congenital transmission, 683.
  - inherited macrocytic in mice, 612.
  - nutritional, of rats, use of radioactive copper in, 412.
  - pernicious, pantothenic acid absorption in, 566.
- Anemone coronaria** infection with *Tranzschelia pruni-sponosae*, 495.
- Angiopteria evecta** petiole, undifferentiated cells in, shapes of, 746.
- Angoumois grain moth** on rice, U.S.D.A. 73.
- Animal(s)**—see also Cattle, Livestock, Mammals, Sheep, etc.
- and man, bacterial infections and parasites common to, U.S.D.A. 97.
  - benefits from forest fungi and insects, 359.
  - body areas, fiber diameter studies, 513.
  - deficiencies, relation to soil composition, Tex. 21.
  - diseases—see also specific diseases.
  - and insect control, fundamentals of, U.S.D.A. 97.
  - and parasites, 523.
  - and parasites in Great Britain, 384.
  - control, 523.
  - control in Great Britain, wartime, 814.
  - new host-parasite records, 384.
  - parasitic, report of committee on, 814.
  - relation to nutrition, 520.
  - studies, U.S.D.A. 676.
  - transmissible, report of committee on, 814.
  - domestic, growth and development, Mo. 320.
  - farm, breeding and improvement, 468.
  - farm, damage to reproduction by vitamin A deficiencies, Ohio 318.
  - farm, diseases, relation to nutrition, 241.

## Animal(s)—Continued.

- farm, nutritional diseases, U.S.D.A. 97.  
 fats, *see* Fat(s).  
 herbivorous, role of vitamin B complex in nutrition, Tex. 85.  
 husbandry experiments, design, 513.  
 husbandry group, committee on policy, report, 797.  
 husbandry in India, 85.  
 imported, and products, inspection and quarantine, U.S.D.A. 676.  
 industry in Tucumán during last 60 years, progress, 867.  
 normal and bloated, ruminal gases in, 90.  
 nutrition—  
   potassium in, 134.  
   relation to disease in farm animals, 241.  
   role of carotene in, 232, 374.  
   zinc in, 456.  
 parasites, *see* Parasites.  
 photosensitization of, Tex. 99.  
 preparation of carcasses for chemical analysis, 729.  
 production in post-war world, 796.  
 proteins, nutritive value, 231.  
 sanitation and disease control, 523.  
 small, autopsy examinations of, R.I. 384.  
*Anopheles*—*see also* Malaria and Mosquito(es).  
   breeding along irrigation canals, Paris green for control, automatic distribution, 657.  
   larval, identification in Georgia, 370.  
 Anoxia, relation to visual system, 130.  
 Ant(s)—  
   as predators of screwworm larvae, 795.  
   control, Nebr. 73.  
   invasion of houses by, 654.  
   of Utah, 664.  
   poisons, sweetened, effect on bees, 510.  
   termites, and plants, ecological relations, 311.  
   white, *see* Termite(s).  
*Antestia* in Kenya, food and feeding habits, 658.  
 Anthelmintics, bio-assay technic for, 823.  
*Anthonomus*—  
   *eugeni*, *see* Pepper weevil.  
   *grandis*, *see* Boll weevil.  
   *scutellaris*, *see* Plum gouger.  
   *signatus*, *see* Strawberry weevil.  
 Anthrax—  
   case reviews and results of use of sulfonamide compounds, 815.  
   studies, U.S.D.A. 97, 676.  
   symptomatic, *see* Blackleg.  
*Anthrenus scrophulariae*, *see* Carpet beetle.  
*Anticarsia gemmatilis*, *see* Velvetbean caterpillar.  
*Atricola* new genus, notes, 512.  
 Aututrin-S injection in pregnant rats and rabbits, fetal survival following, 751.  
*Anuraphis roseus*, *see* Apple aphid, rosy.  
*Aonidiella*—  
   *aurantii*, *see* Red scale, California.  
   *citrina*, *see* Yellow scale.

*Aphanomyces eutiches* on peas, N.Y.State 66.

*Aphanotus parallelus* in insect nests, 73.

## Aphid(s)—

- coecnellid predator of, establishment, P.R. 653.  
 control on collards, 782.  
 control, reduced spray concentrations for, N.Y.State 786.  
 guide to phylogeny, 658.  
 living, staining, simple method, 658.  
 redbud, studies, Kans. 655.  
 transmission of narcissus mosaic virus by, 495.  
 woolly, *see* Apple aphid, woolly.  
*Aphidius matricariae*, bionomics, 371.  
 Aphis—  
   *abbreviata*, winter hosts in New Brunswick, 223.  
   *fabae*, summer host, 503.  
   *gossypii*, *see* Cotton aphid.  
   *maidis*, *see* Corn leaf aphid.  
   *rhumini*, transmission of potato virus Y by, 210.

*Aphyus* spp., effect of dormant sprays on, 511.

*Aphytis mytilaspidis*, effect of dormant sprays on, 510.

## Apiary(ies)—

- inspection, Conn.[New Haven] 499.  
 location, Okla. 783.

*Aplanobacter michiganense*, breeding for tomato resistance to, 213.

## Apparatus --

- for collecting salt particles from atmosphere, 177.  
 for determination of carbon in soils, 728.  
 for production of artificial frost injury to trees, 29.  
 Landegård's, construction and use, 433.

## Apple(s)—

- alternate bearing in, 479.  
 and cider jelly, preparation, 11.  
 aphid(s)—  
   new sprays for, Ohio 362.  
   rosy, control, 363.  
   rosy, control, new phases, N.Y.State 785.  
   woolly, notes, N.C. 500.  
   woolly, root form, cyanide for control, 787.  
 biennial bearing—  
   control by defoliation, Mo. 47.  
   prevention, Vt. 476.  
 bitter pit in McIntosh variety, U.S.D.A. 343.  
 bitter pit, nature and causes, Bt. 476.  
 bitter rot control, N.C. 485.  
 bitter rot in Missouri, control, 214.  
 black root rot, distribution and severity, 214.  
 black rot situation in 1941, R.I. 344.  
 bland sirup production from, 441.  
 biotch, eradicant sprays for, 356.  
 blotch studies, Okla. 356.  
 boric acid for, Mont. 628.  
 branch ringing, effect on set and size of fruit, Mo. 47.

## Apple(s)—Continued.

branches, pruned and unpruned, of various ages, performance, Mo. 47.  
breeding, 179.  
cankers, perennial, *Epicalthma coloradella* inhabitant of, 369.  
commercial hand pollination methods for, 633.  
composition, effect of orchard fertilizers, 195.  
condition, harmful effect of bruising, Pa. 628.  
crab, *see* Crab apple.  
crop, thinning by spraying at blooming, 50.  
crown rot studies, 357.  
cuttings taken in May, root-inducing substances effective on, 479.  
Delicious, comparison of varieties as pollinizers, 335.  
Delicious, effect of November 1940 freeze, 179.  
Delicious, mealiness and quality, factors affecting, 337.  
developing fruit, gross morphology and histology, 335.  
diseases in Colombia, control, 491.  
Duchess, coloring, effect of sodium thiocyanate, Nebr. 47.  
early, red varieties, Ohio 50.  
effect on urinary acidity and blood alkali reserve, 277.  
emergency uses for, U.S.D.A. 723.  
fertilizer experiments, N.Y.State 193.  
finish and keeping quality, effect of spray materials, Mich. 766.  
fire blight, extreme epidemic, 203.  
fruits, gaseous emanations of one lot. effect on another 51.  
fruits, histology and development, N.Y. State 193.  
fruit set, effect of ringing, Ohio 331.  
Golden Delicious, russetting, 195.  
growth as affected by sprays, R.I. 331.  
handling from tree to table, U.S.D.A. 51.  
in cold storage, water loss from, cause, 337.  
insects, nonsulfur sprays with special stickers v. standard materials for control, Conn.[New Haven] 499.  
Jonathan, pectic changes in, as measure of ripening under differential carbon dioxide treatments, 51.  
juice composition, relation to yeast multiplication, 601.  
juice packed in 1940, survey, 296.  
juice, preservatives, chloroacetic acids as, 10.  
leafroller, new, N.Y.State 785.  
leaves, internal structure and chlorophyll in, effect of sprays, Kans. 633.  
leaves, photosynthesis and transpiration, effects of leafhopper feeding injury, 213.  
leaves, sampling known areas for chemical analysis, 782.

## Apple(s)—Continued.

maggot and mites, 230.  
maggot control, Conn.[New Haven] 499, N.Y.State 785.  
maggot, emergence, migration, and control, 363.  
maggot sprays, making effective, 363.  
maturity, days from bloom as index, 51.  
McIntosh, brown core in, development in storage, 633.  
McIntosh, preharvest drop, effect of boron application, 335.  
McIntosh, respiration, effect of controlled-atmosphere storage, 337.  
moldy core in Wisconsin, 357.  
narrow-leaf variation, 480.  
Northern Spy, internal break-down in storage, Mich. 633.  
orchard, continuous cultivation in, harmful effects, Pa. 628.  
orchard, Rome Beauty, response to tillage, 632.  
orchard, Von Osten, analyses of fertilizer data from, 632.  
pomace, waste, important outlet for, N.Y.State 735.  
preharvest drop—  
control methods, 336.  
reducing with hormone sprays, R.I. 331.  
sprays, effectiveness, relation to temperature, 336.  
sprays for, 194, Kans. 628.  
production in southern New Jersey, N.J. 766.  
red color increase, effect of certain chemicals, 194.  
red strains, time to pick, Ohio 331.  
respiration and oxidase and catalase activity, relation to maturity and storage, 480.  
response to preharvest sprays, varietal differences, 194.  
rootstocks, dwarfing and seedling, tests, N.Y.State 193.  
rootstocks, improved, problems of, N.Y. State 766.  
rot fungus, related to human pathogen, 491.  
rust diseases, epidemiology and control, N.Y.State 203.  
sawfly on Vancouver Island, 500.  
scab—  
control, 357, Mo. 47.  
control at Glasnevin, Ireland, 214.  
control in Hudson Valley, N.Y.State 203.  
control, lime-sulfur for, Kans. 628.  
control, new spray materials for, U.S.D.A. 627.  
control program, averting spray injury in, N.Y.State 203.  
control, spray materials for, Vt. 485.  
control, spraying for, Mo. 59.  
development and comparison of fungicides for, R.I. 344.

## Apple(s)—Continued.

## scab—continued.

epidemiology, factors affecting, 357.

fungus, maturation and discharge of  
ascospores, Ind. 776.

in Missouri, control, 214.

seedlings of Rome Beauty, Gallia Beauty,  
and Golden Delicious, fruit character-  
istics, 179.spray, nonresidue, schedule, improvement  
in, N.Y.State 785.spray program for, shortened, intensive,  
N.Y.State 785.

spray residues removal from, U.S.D.A. 50.

spraying, Pa. 652.

stocks, hardy, budding and grafting on,  
Ohio 50.storage in modified atmospheres, N.C.  
476.

storages, refrigerated farm, Ohio 260.

time interval between full bloom and  
fruit maturity, 334.

## tree(s)—

borer, flatheaded, biology and con-  
trol, Okla. 228, 783.

cultural needs, Kans. 628.

distribution of nitrogen and car-  
bohydrates in, Mo. 335.

fertilization, Vt. 476.

fertilization, spring v. fall, Mo. 47.

filler, and management, Ind. 766.

growth and yield, effect of sulfur  
and copper sprays, 648.

most productive age, Ohio 331.

nitrogen requirements, U.S.D.A. 627.

pruning, Ark. 762.

spraying with naphthaleneacetic  
acid and derivatives, Vt. 476.Steele Red, growth and yield, effect  
of double-worked interstocks, 480.Wealthy, time of blossom induc-  
tion, 50.

wound dressings on, U.S.D.A. 68.

young, effects of nitrogen, Vt. 31.

young, effects of submersion of roots  
in water, 632.young, induction of flower bud for-  
mation in, Mo. 47.young, on clonal stocks, trunk diam-  
eters, 480.varieties, behavior following Nov. 1940  
freeze, 50.varieties top-worked on Virginia Crab,  
fruiting, 480.

variety tests, Miss. 191.

Washington, marketing in Los Angeles,  
Wash. 268, 695.

water core, factors involved, 337.

winter injury, reducing, N.Y.State 193.

## Apricot(s)—

kernels, debittering, 441.

orchards, border trees, relative yields,  
632.

unsulfured, drying experiments, 296.

*Arachis*, wild species, fruits of, 25.

## Aralac—

fiber, properties, 285.

new fiber made from cow's milk, 285.

## Archips—

*argyrospila*, see Fruit tree leaf roller.*fumiferana*, see Spruce budworm.*Arge macleayi* on hazelnut, 664.*Argyrothia laevigatella*, biology and natural  
control, 650.*Argyrotaenia citrana*, see Orange tortrix.

Arkansas Station notes, 427, 721.

Arkansas Station report, 142, 867.

Arkansas University notes, 427, 721.

## Army—

food and fighting efficiency, 547.

rations, vitamin supplementation, rela-  
tion to fatigue and ability to do mus-  
cular work, 706.

subsistence, research in, 410.

## Armyworm(s)—

control in wheat, timing in relation to,  
Okla. 783.

fall, control, Ark. 72.

in wheat, control with poisoned bait, 81.

Arsenic, colorimetric microdetermination  
after evolution as arsine, 730.

Arsenic, water soluble, ultimate value, 782.

Arsenicals, effect on cotton aphid, predators,  
and other insects, 361.Arteriosclerosis in clinical case of John's  
disease, 243.

Arthritis in lambs, Mont. 676.

## Ascaridia—

*dissimilis* in turkeys, life history, 384.*galli* eggs, studies, 815.*galli*, resistance of chickens to, Kans.  
676.

## Ascaris—

sp., parasite of squirrel, 497.

spp. anthelmintic efficiency of Flcin  
against, 247.*Ascochyta pinodella* on peas, N.Y.State 66.

Ascorbic acid—see also Vitamin C.

blood plasma, determinations in mass  
studies in human nutrition, Pa. 715.concentration in blood, effect of hyper-  
pyrexia, 715.daily intake required to maintain ade-  
quate amount in blood plasma, 560.excretion at known levels of intake, rela-  
tion to capillary resistance, dietary  
estimates, and human requirements,  
562.

improved photometric method for, 735.

in blood of dairy cattle, variations in,  
810.in blood plasma and urine, determina-  
tion, 153.in blood plasma, rate of increase after  
ingestion of this vitamin, 561.

in body fluids of horses, 103.

in buffaloberry, 861.

in expressed vegetable juice, 559.

in fruits and vegetables, factors in pro-  
cessing affecting, 713.

**Ascorbic acid—Continued.**

- in grapefruit juice canned by various processing methods, 860.
  - in honey of different localities, 551.
  - in milk, relation to volume of milk produced, 238.
  - in normal adults, urinary excretion and plasma concentration, effect of controlled ascorbic acid ingestion, 419.
  - in persimmon leaves and fruits, 861.
  - in plant life, physiological activity, 29.
  - in prepared foods, 281.
  - in rhubarb, 559.
  - in rose hips and rose-hip sirups, 862.
  - in small fruits, 861.
  - in summer squash, loss during cooking, 862.
  - in tomato catsup, 862.
  - in tomato, effect of mineral nutrition, 560.
  - in tomato juice, effect of processing Ark. 845.
  - in whole blood, clinical estimation, 735
  - physiological activity in plant life, 713
  - plasma and dietary, relation, 561.
  - requirement of children, 420, 862.
  - requirement of premature infants, effect of diet, 560.
  - storage in vitamin A deficient hens, 803.
  - synthesis in excised tomato roots, 29.
  - tolerance test and application to senile and schizophrenic patients, 562.

activities, Tex. 73.

activity, relation to orange nectar and pollen, 83.

behavior, effects of sulfur compounds applied during bloom, 362.

bread and royal jelly, vitamins in, 82.

caged, longevity, factors affecting, 795.

feeding with soybean flour as pollen substitute, 83.

foulbrood, *see* Foulbrood.

larvae, susceptibility to individual inoculations with *Bacillus larvae* spores, 795.

management manual, 272.

median lethal dose of calcium arsenate for, 499.

nests as reservoirs and sources of stored products pests, 73.

package, *Nosema apis* in, 663.

poisoning in Washington, 81.

pollen requirements of a colony, 83.

queen, one and two-year-old, 228.

queen rearing, Tex. 73.

studies, Kans. 655.

usefulness in pollination, U.S.D.A. 228.

**Beef**—*see also* Cattle, beef.

aged, effect of freezing on tenderness in, 272.

dark cutters in, Kans. 666.

dehydrated, methods for production, U.S.D.A. 700.

finish and quality, effect of ratios of concentrates to lespedeza hay on, U.S.D.A. 665.

improvement, plans at station for, Utah 233.

increased production from same number of cattle, Nev. 233.

liver catalase, preparation by use of acetone or alcohol, 728.

**production**—

crossbreds for, 181.

effect of mineral and carotene feeding, Tex. 85.

increasing after the war, 796.

maximum, from mountainous summer range, Utah 233.

with minimum-for-efficiency investments, Miss. 537.

with minimum grain and maximum roughage, Mo. 84.

quality, effect of ultraviolet light and temperature during aging, 513.

**Beef**—Continued.

quality produced on cottonseed meal and hulls, U.S.D.A. 665.

quality, relation to ultraviolet light and temperature during aging, Wash. 847.

U. S. grades, relation to palatability of porterhouse steaks, Mo. 127.

**Beekeeping**—

industry in Montana, Mont. 655.

two-queen hive system, value, Ohio 362.

**Beer**, vitamin B complex in, 856.**Beet(s)**—*see also* Sugar beet(s).

application of sodium nitrate, R.I. 331.

break-down in, boron for prevention, 646.

dehydrator for, Colo. 849.

dried, made into bricks freed from air in new packaging process, N.Y.State 850.

effect of storage on betanin and sucrose in, and importance in breeding program, 629.

germination and yield, effect of carbon black, R.I. 331.

internal break-down, [N.Y.]Cornell 207.

leafhopper, importance of birds in checking, Utah 653.

molasses rations for pigs, nutritional inadequacy, Utah 516.

planting methods, 763.

scab in New York fields, U.S.D.A. 343.

seed, sheared, treatment, 487.

seed treatments, Tex. 59.

sugar, *see* Sugar beet(s).

variety tests, Ga.Coastal Plain 331.

webworm, notes, Mont. 655.

**Beetles**, wood-boring, of Saanich, Vancouver Island, 500.**Belladonna**, insects attacking, 781.**Bemisia marginata**, *see* Raspberry root borer.**Bentgrass(es)**—

Colonial, development, effect of soil temperature, 43.

Colonial, seasonal development of roots, R.I. 326.

for pasture, breeding, R.I. 326.

varieties and strains, fertilizer tests, R.I. 326.

varieties and strains, seed production, R.I. 326.

velvet, seed production, R.I. 328

**Benzimidazole derivative**, characterization of lactic acid as, 725.**Bermuda grass**—

production of roots, rhizomes, runners, and leaf shoots under different conditions, 185.

protein and mineral content, Ga. 579.

**Berries**, *see* Fruits, small, and Raspberry (ies), Strawberry (ies), etc.**Betaine**, structural specificity in transmethylation, 702.**Beverages**—

and food analyses, 406.

taste and flavor, factors affecting, 296.

dairy, dry meal v. skim milk powder for, Mont. 671.

diarrhea, 523.

fattening, Kans. 666.

fattening, cottonseed cake v. corn in ration, Miss. 86.

fattening rations compared, Mich. 233.

fattening, supplements to corn and silage for, Nebr. 84.

feeder, use of silage for, Ark. 797.

goiter in, prevention with iodized salt, Mont. 676.

growth, digestible nutrient requirements, Vt. 520.

mammary gland development, relation to later milk production, U.S.D.A. 670.

milk substitute v. skim milk for, Tex. 92.

nutrition, carotene in, 95.

nutrition, review, 95.

on pasture, creep feeding, Ga. 666.

on rations low in potassium, lesions of Purkinje fibers of heart resulting from, 243.

passage of liquids into rumen, factors affecting, 94.

persistent foramen ovale and multiple defects of interventricular septum, 527.

raising on Coyner nipple pail, Kans. 671.

raising on minimum of milk, Alaska 666.

**Calf(ves)**—Continued.

raising, war emergency plans for, 811, Ohio 880.

scours, nutritional studies on, 90.

thyroidectomized, growth and metabolism, Mo. 92.

vealer, production, Kans. 671.

wartime rations for, 521.

wintering and fattening, soybean meal for, Nebr. 84.

**California**—

prionus, life history and control, N.Mex. 78.

Station notes, 427.

University notes, 427.

*Camassia*, gametophyte development and fertilization in, 465.

Canalgre tests for tannin, Tex. 25.

*Candida krusei*, effect on heat resistance of lactic acid bacteria, 96.

Candy making, fruit as sugar savers in, 10.

Cankerworms, studies, Kans. 655.

Canneries, fruit and vegetable, economic study, S.C. 404.

**Canning**—

methods, home, Calif. 409.

v. freezing, 295.

with pressure cooker, W.Va. 129.

Cantaloup, *see* Muskmelon(s).

**Capillaria**—

*caudinflata* of chicken and turkey, earthworms as possible hosts, 384.

*longipes*, percentage incidence in cattle, 101.

Capillary resistance, abnormal, in swine suffering from an inherited bleeding disease, 684.

Capons, feed utilization by, breed variations in, Okla. 797.

*Caragana arborecens*, formation of adventitious roots, 457.

**Carbohydrate**—

characterization, 725.

of complete diet, digestion and absorption, effect of vitamins and yeast, 135.

**Carbon**—

dioxide, fixation by pigeon liver in dissimilation of pyruvic acid, 583.

in soils, determination, accurate wet combustion method, 728.

**Carnation(s)**—

bacterial wilt in Indiana, U.S.D.A. 203.

breeding, N.C. 476.

field-grown, *Platynota stultana* as pest, 70.

greenhouse, tartar emetic for thrips control on, Wash. 503.

sleepiness in, 55.

Carob, aerial root system of, significance, 316.

**Carotene**—

absorption and retention by hens on normal and low fat rations, 803.

absorption, metabolism, and storage, 413. analysis, relation to isomerization of  $\beta$ -carotene, 484.

$\beta$ - and neo- $\beta$ , determination with visual spectrophotometer, 484.

## Carotene—Continued.

- and vitamin A, utilization in rat, 551.
- balance experiments with cows and bullocks, 374.
- chromatographic determination, activation of dicalcium phosphate for, 436.
- destroying power of animal protein feed, Tex. 85.
- in expressed vegetable juice, 559.
- in Michigan-grown hay for dairy cattle, Mich. 238.
- in peaches, Ark. 845.
- in plant material used for hay, stability, 374.
- in plants, determination, 152.
- $\beta$ -, in prepared foods, 281.
- in range grasses and content of some feeding stuffs of South Africa, 232.
- in Texas range forages, 798.
- leaf, determination method, 8.
- new source of, 855.
- (provitamin A), requirements of dairy cattle for conception, 90.
- relation to animal nutrition, 232.
- requirement of calves, 95.
- requirements of cattle, sheep, and swine, 798.
- stability and tocopherol, 855.
- utilization by beef animals, relation to protein supplements, Tex. 85.

## Carotenoid(s)—

- and vitamin A, determination in feces, 153.
- biologically active, and vitamin A, 413.
- in prepared foods, 281.
- of telial galls of *Gymnosporangium juniperi-virginianae*, 216.
- pigments from mineral oil, separation and characterization, 26.
- pigments of cryptogams, 310.
- pigments, pure, preparation and absorption spectra, 292.
- provitamin A, assays of, 9.
- studies, 434, 435, 436.

## Carpet beetle—

- black, natural habitat for, 72.
- Laelius* sp., parasite of, 500.

## Carpet grass—

- effect of lime and fertilizer mixtures, 759.
- pastures, improvement by disking and legumes, N.C. 473.

*Carpocapsa pomonella*, see Codling moth.*Carpophilus dimidiatus*, see Corn sap beetle.

## Carrot(s)—

- Alternaria* leaf blight, Tex. 60.
- branched roots of, factors affecting, 629.
- breeding and improvement, Nebr. 47.
- Cercospora* blight of, 775.
- Chantenay, quality in, relation to seed production, 48.
- dehydrated and fresh, vitamin A value, 281.
- dehydration tests, 849.
- dehydrator for, Colo. 849.
- diseases, Ohio 344.
- dried, made into bricks freed from air in new packaging process, N.Y.State 850.

## Carrot(s)—Continued.

- ensiling for milk production, Ohio 380.
  - fertilizer tests, R.I. 326.
  - rust fly, biology, 370.
  - rust fly, fluctuations in population, 370.
  - seedstalk development, effect of infecting with certain viruses, 211.
  - seedstalk development, effect of temperature and photoperiod, 630.
  - variety tests, Ga.Coastal Plain 381.
- Cassava diseases and control in Brazil, 642.
- Castor-bean(s)—
- culture tests, Tex. 42.
  - production tests, Kans. 618.
  - sheller, 259.
  - thresher, construction, Ky. 833.
  - variety tests, Ga. 617, Nebr. 41, Tex. 42.
- Castor oil to replace tung oil, use, U.S.D.A. 627.
- Catalase, preparation and properties from different sources, 728.
- Catalpa—
- damage due to recreational use, 496.
  - sphinx, cankers associated with, 496.
- Cataract—
- formation in rats, relation to riboflavin, 417.
  - in rats, Mo. 135.
- Cutarrh., infectious, of chickens, transmission tests to mice and rats, 391.
- Catenotaenia* sp., parasite of squirrel, 497.
- Caterpillar—
- red-headed, on peanut and partridge pea, Ga. 654.
  - red-humped, notes, Mont. 655.
- Cations, surface active, antibacterial action of, 457.
- Cats, diseases and parasites, U.S.D.A. 98.
- Cattle—see also Calf(ves), Cow(s), Heifer(s), Livestock, and Steers.
- apparently normal, occurrence of *Bar-tonella* in, 384.
  - Ayrshire, growth studies, body weights and heights at shoulders, 808.
  - baby beef, fattening, rations for, Oreg. 666.
  - beef—
- Alyc-clover v. Kobe lespedexa as maintenance feed for, Miss. 325.
  - and dual-purpose, muscle-bone ratio as index of merit, 513.
  - breeding and feeding tests, Mont. 663.
  - enterprise, farmer experience with, La. 397.
  - fattening, blackstrap molasses for, Tex. 85.
  - fattening, comparison of rations for, Ga. 666.
  - fattening, linseed meal v. cottonseed meal for, Tex. 85.
  - fattening rations, Tex. 85.
  - fattening rations, dried citrus pulp in Tex. 86.
  - fattening, vitamin A requirements, Tex. 85.

**Cattle—Continued.****beef—continued.**

- feeding and performance tests, Mont. 666.
- for breeding purposes, U.S.D.A. 374.
- forest grazing with, 797, N.C. 514.
- grazing and dry-lot feeding on various grasses, U.S.D.A. 665.
- management and production methods, Mo. 84.
- production and forest grazing, Ga.Coastal Plain 232.
- rations for, Nebr. 84.
- vitamin A requirements, Tex. 85.
- wintering, Ga. 666.
- wintering, roughages for, Fla. 232.
- blood, chemical composition, 94.
- breeding, management, and judging, 230.
- daily weights, nonrandomness of variations in, 515.
- dairy—*see also* cow(s).
  - and milk products, studies, Ohio 380.
  - balancing rations for, 808.
  - butterfat production in, heritability, 810.
  - conception in, vitamin A requirements, Tex. 92.
  - culling and progeny testing, value of short-time records for, 610.
  - effect of inbreeding on birth weight, growth rate, and type, 181.
  - feeding, new developments in, 520.
  - feeding value of sweetpotato meal and peanuts on vine, Ga. 671.
  - grazing habits, 671.
  - importance of adequate feeding, Miss. 92.
  - judging, U.S.D.A. 238.
  - lactating, basal energy metabolism, Mo. 92.
  - legume v. nonlegume dry roughage for, Tex. 92.
  - nutrition, vitamin C in, 90.
  - pastures and feeding for, Ga.Coastal Plain, 380.
  - prairie hay for, Okla. 808.
  - reaction time to electric shock, effect of age and weight, 520.
  - respiratory quotient in, effect of fasting and refeeding, Mo. 92.
  - resting maintenance cost in, 90.
  - selection for conformation in, 94.
  - simple v. complex rations for, 90.
  - vitamin A requirements, 807.
- diseases—*see also specific diseases.*
  - and parasites, U.S.D.A. 97.
  - common, 243.
  - special report, U.S.D.A. 243.
- dual-purpose, breeding studies, U.S.D.A. 800.
- effects of copper intake on, 527.
- fattening—
  - barley for, Mo. 84.
  - cracked Early Kalo and cracked corn for, Nebr. 84.

**Cattle—Con-****fattening—continued.**

- mineral requirements, Kans. 666.
- rations, sorghum roughages and grains in, Kans. 666.
- soybean meal v. cottonseed meal for, Nebr. 84.
- vitamin A deficiencies in, U.S.D.A. 665.
- feces, androgenic substance in, 753.
- feed production, rotation pastures v. cultivated crops, Mo. 41.
- feeder, disenses, Kans. 676, 678.
- feeder, purchasing, Mich. 233.
- for Tropics, U.S.D.A. 515.
- gastrointestinal nematodes, in southeastern United States, 100.
- gastrointestinal parasites in, Tex. 99.
- giving low titer reactions to Bang agglutination test, Mo. 99.
- grazing and dry roughages for, Okla. 797.
- grazing logged-off land with, Oreg. 666.
- grazing on improved v. unimproved pastures, Ga. 666.
- grazing on *Phalaris tuberosa*, staggers syndrome in, 528.
- grazing preferences, Nebr. 42.
- growth, limiting factors for in grain and timothy hay, U.S.D.A. 670.
- growth rate and efficiency of weight increment, effect of thyroxine, 91.
- grubs, control, Miss. 499, U.S.D.A. 98.
- grubs, control in range cattle, 781.
- heat disposal and tolerance in, U.S.D.A. 665.
- herds, Holstein and Jersey, line-breeding, Mo. 34.
- herds, institutional, inheritance of milk-producing capacity in, Pa. 671.
- herds of the station, N.Dak. 373.
- Holstein, body weight, relation to resting energy metabolism and ventilation rate, Mo. 320.
- Holstein-Friesian and Jersey, development of improved strains, U.S.D.A. 670.
- hornfly control, new larvicide for, 227.
- hybrid beef, paper on, 797.
- hybrid beef, production, breeding methods, 610.
- hydrocephalus, a lethal in, 468.
- in semiarid regions of Union of South Africa, bionomic studies, 323.
- injuries caused by ingesting foreign objects, U.S.D.A. 98.
- internal parasites, 523.
- Jersey, development of high producing strain, Mo. 34.
- lice, U.S.D.A. 98.
- livers, hard yellow, Tex. 99.
- lungworm, life history, 680.
- lungworm, survival of preparasitic stages on pastures, 384.
- mineral deficiencies in, U.S.D.A. 665.

## Cattle—Continued.

- new disease characterized by nervous disorder, Tex. 99.
- nutrition, new developments in, 514.
- on bitterweed ranges, maintenance, Tex. 85.
- on phosphorus-deficient range, effect of supplying phosphorus on beef production, 513.
- parasites and treatment for removal, U.S.D.A. 676.
- pasturing and feeding tests, U.S.D.A. 670.
- plague, *see* Rinderpest.
- poisoning, *see* Plant(s), poisonous, and specific plants.
- Polled Hereford, establishment of superior strains, Ga.Coastal Plain 373.
- population, purebred Aberdeen Angus in United States, 1900 to 1939, breeding structure, 610.
- prenatal development, Minn. 181.
- producing farms in Coastal Plain, survey, N.C. 115.
- range beef, fertility in, 610.
- range, Squaw Butte, proximity of water on, Oreg. 666.
- rumen gases and bloat in, Oreg. 676.
- scab and control, U.S.D.A. 98.
- sex ratio in, 472.
- temporary winter pastures for, Ga. 666.
- thyroidectomized, age changes in, Mo. 320.
- thyroidectomized, growth and energy metabolism, 91.
- ticks, *see* Tick(s).
- toxicity of tung tree foliage to, Fla. 526.
- vitamin A and carotene requirements, 793.
- wheat as feed for, Utah 667.
- wintering rations for, Nebr. 521.

## Cauliflower—

- black rot resistance, breeding for, N.Y.State 203.
- growth and yield, effects of partial defoliation at transplanting time, U.S.D.A. 47.
- thiamin determination in, 438.

## Cecitis in rats—

- prevention by succinyl sulfathiazole, 816.
- prophylactic effect of sulfaguanidine against, 816.

## Cedar—

- eastern red, *Phomopsis* blight, Nebr. 59.
- rust, *see* Apple rust.
- seedling blight in Puerto Rico, U.S.D.A. 71.
- western red, heartwood decay, variability in resistance to, 70.

## Celery—

- blight, western, virus-induced, 343.
- calico on delphiniums and other host plants, Calif. 69.
- early blight, Ohio 344.

## Celery—Continued.

- growth and yield, effects of partial defoliation at transplanting time, U.S.D.A. 47.

"hollow stalk" in, causes, R.I. 831.

- seedlings on Everglades muck, effect of starter solutions, 191.

## Cell division, effects of colchicine, 746.

## Cellulose—

- deterioration by fungi, determining, 716.
- fibers, structure of, review, 571.

## Celtuce—

- disease symptoms caused by bean leafhopper, 640.
- downy mildew, U.S.D.A. 58.
- Septoria* leaf spot, U.S.D.A. 640.

*Cephus cinctus*, *see* Sawfly, wheat stem.*Ceratitis capitata*, *see* Fruitfly, Mediterranean.*Ceratonia catalpae*, *see* Catalpa sphinx.*Ceratostomella*—

- additional species in United States, 601.
- and related fungi, vitamin deficiencies, 742.

*ulmi*, isolation from insects attracted to felled elm trees, 781.

*ulmi*, specificity of pyridoxin for, 70.

*Cercopidae* in North America north of Mexico, host plant records, 222.*Cercospora*—

- blight of carrot, 775.
- diazii*, notes, U.S.D.A. 58.
- leaf blight of sugar beets, control, Ohio 344.
- leaf spot on peanut, Tex. 59.
- oryzae* in rice, physiologic races, inheritance and linkage of factors for resistance to, 608.
- oryzae*, physiologic specialization in, 642.
- spp., new leaf-infecting, of Oklahoma, 485.

*Cercospora herpotrichoides*, cause of wheat eyespot in Great Britain, 772.Cereal(s)—*see also* Grain(s) and specific grains.

- and cereal products, nicotinic acid in, assay, 732.
- and seed products, U.S.D.A. 723.
- as food, 407.
- cellulose, roughage material for experimental animals, 407.
- diseases in 1942, U.S.D.A. 58.
- diseases, studies, Kans. 640.
- products, nicotinic acid in, 556.
- products, nicotinic acid in, determination, nature of interfering chromogens, 437.
- seed germination and seed-borne disease in, nonsterile soil as medium for tests, 771.
- seed treatment, *see* Seed treatment.
- smuts, Oreg. 641.
- take-all disease, 348.

## Cereals—Continued.

waxy starches (replacing tapioca) from, U.S.D.A. 617.

Cerebrospinal fluid pressure in cattle, method for determination, 680.

*Chaetomium globosum*—

growth, new culture medium for, 286.  
on cotton fiber and yarn, oxygen absorption and catalase production during growth, 424.

Chafer, European, importance and control, N.Y.State 785.

*Chalocodermus aeneus*, see Cowpea curculio.

*Chaoborus astictopus*, see Gnat, Clear Lake.

Chaparral, fire control in California, measuring efficiency, 202.

## Cheese—

action of enzyme preparation from chicken stomach on, 92.

## Cheddar—

American, in valve-vented cans, manufacture, curing, and merchandising, 520.

American, new method for manufacturing, 807.

and Limburger, gases evolved by, 92.  
curing, 807.

lipase activity in, effect of copper, 813.

prepared with starter v. pure cultures, 92.

short-cure, quality relation to temperature exposures, Tex. 92.

types of bacteria developing in and cause of low-grade cheese, U.S.D.A. 671.

year-old vacuum-canned, conditions necessary for maintaining quality, 240.

cottage, making from reconstituted skim milk powder, 807.

cottage, quick freezing and storage, 807.

curd, pitching consistency, simplification of Scott Blair-Coppen test for, 382.

curing period, reducing length of by new starter, Pa. 671.

factory and storage room, use of ultra-violet rays in, 96.

flavor defects of, evaluation, 96.

grading clinics, value for educational purposes, 813.

making, 813.

making problems in South, 807.

pasteurized milk, canning, 92.

quality, relation to bacteria from water sources, 239.

relation of bitterness to flavor in, Miss. 238.

ripening in cans, N.Y.State 521.

Romano-type, use of rennet paste in, 92.

scoring, comparative standardization, 814.

solvent, orthophosphoric acid as, 674.

Swiss, starter activity, effect of heat treatment and source of milk, 813.

Swiss, textbook, 240.

## Cheese—Continued.

Swiss, types of bacteria developing in and cause of low-grade cheese, U.S.D.A. 671.

*Chelloneurinus microphagus*, effect of dormant sprays on, 511.

Cheilosia, response to vitamin therapy, 554.

*Chelonus*, methods of rearing, 361, 654.

Chemicals, water-soluble, fungicidal v. fungistatic effect on fungus spores, 770.

*Chenopodium quinoa* anatomy and chemical composition, 315.

## Cherry (ies)—

boric acid for, Mont. 628.

carbon dioxide treatment for shipment, U.S.D.A. 627.

dehydrator for, Colo. 849.

edible, overgrowth produced by, on Sargent cherry, 481.

fruitfly control, Oreg. 655.

leaf miner, notes, N.Y.State 785.

## leaf spot—

and brown rot control, Oreg. 641.

control by fixed coppers and bordeaux, Ohio 344.

epidemiology and control, N.Y.State 203.

fungus causing fruit spotting, U.S.D.A. 202.

maraschino, preparation, N.Y.State 272.

Montmorency, cultural tests, N.Y.State 193.

orchard, limiting period of clean cultivation in, Mont. 628.

physiological (?) bud blight, Oreg. 641.

preparing for frozen food lockers, 700.

rootstocks, comparison, Utah 634.

sour, yellow leaf disease, 68, 215.

time interval between full bloom and fruit maturity, 334.

tissue, stability of erythrosine dye in, Oreg. 579.

trees, leguminous cover crops for, value, Mont. 628.

## Chestnut—

blight in California, 650.

blight-resistant, timber type, breeding for, 610.

blight-resistant varieties, breeding for, U.S.D.A. 627.

blight, studies, 343.

ink disease, 216.

## Chick(s)—

action of diethylstilboestrol in, 322.

assays, basal rations for, 378.

backyard hatching and brooding, N.J. 88.

brooders, homemade electric, Okla. 797.

brooders, insulated electric, adaptation in uninsulated poultry houses, Nebr. 105.

brooding, use of electricity in, Mo. 105.

calibration of development under improved conditions of incubation, 88.

cow manure as source of vitamins for, 377.

creatine formation in, 237.

## Chick(s)—Continued.

- day-old, shank color, effect of diet of hen, 517.
  - diseases, combating, 685.
  - dusting with hypochlorite powders, possible irritating effects, 104.
  - effect of starting rations on growth, 376.
  - embryo, early, restitution of tail in, 750.
  - embryo, experimental infection with pseudorabies virus, 387.
  - embryos, chorioallantoic membrane and response to inoculation with mycobacteria, 676.
  - feather growth, dietary factors in, 517.
  - feeding experiments with solvent-extracted tung oil meal, 236.
  - feeding experiments with willow oak acorns, 803.
  - from heterozygous parents, chondrodystrophic progeny, 468.
  - growth, effect of cow manure in diet, 518.
  - growth factors for, 379.
  - hereditary abnormalities in, developmental mechanics, 469.
  - lysine requirement, 669.
  - new growth factors for, evidence of, 518.
  - nutrition, *Lactobacillus casei* factor in, 669.
  - nutrition, nicotinic acid in, 669.
  - nutrition, significance of biotin in, 376.
  - protein requirements, Tex. 85.
  - rations, maximum crude fiber content, Tex. 85.
  - sexing, at hatching, Kans. 325.
  - shank pigmentation, 377.
  - shipping boxes, disinfection with sodium silicate solutions, 826.
  - slipped tendon in, see Perosis.
  - soybean protein as source of amino acids for, 801.
  - supplemental value of grain products, Nebr. 84.
  - utilization of feeds by, Nebr. 84.
  - vitamin D requirement and dietary calcium and phosphorus levels, 804.
  - vitamin E deficient, edema in, 804.
  - well-being, effect of color of light on, U.S.D.A. 665.
  - White Leghorn and crossbred, comparative vitamin D requirements, 518.
- Chicken(s)—see also Chick(s), Fowl(s)  
Hens, Poultry, etc.
- breeding for meat production, Calif. 750.
  - broiler production—
    - feed mixtures for, Miss. 801.
    - prospects and feeds for, Ark. 797.
    - studies, Kans. 686, Miss. 670.
  - crossbred broilers and layers v. purebreds, 876.
  - marketing and pricing in Kentucky, Ky. 841.
  - meat and eggs for export, U.S.D.A. 728.
  - physical and chemical composition, 700.
  - tapeworm studies, Kans. 676.

## Chicory group, rubber from, N.Dak. 624.

## Chigger—

- in lawns, azobenzene for control, 781.
- tropical, in California, 665.

## Children—

- anthropometric and orthopedic examinations, technic for, 131.
- ascorbic acid requirements, 420.
- in college community, nutritional status, 131.
- iron requirement, 411.
- nutrition and chemical growth, evaluation, 851.
- nutritional requirements, 547.
- older school, importance of good nutrition for, Miss. 275.
- preschool, metabolism of, interrelation of calcium, phosphorus, and nitrogen in, 550.
- school—
  - ascorbic acid requirements, 862.
  - better food for, 851.
  - diets of, seasonal survey, Va. 276.
  - physical examination records, relation to scholarship and deportment, Miss. 142.
  - thiamin excretions, 710.

*Chilocorus cacti*, control of scale insects by, P.R. 655.

## Chinch bug—

- damage to sorghum, relation to phosphorus, Okla. 783.
- in sweet corn, Kans. 655.
- new, from Argentina, 366.
- on wheat, Kans. 655.
- studies, Nebr. 73.

## Chinchillas, cross-breeding of, 750.

*Chironomus utahensis*, biology, 500.*Chlamydomonas* susceptibility to colchicine, 463.*Chlorella vulgaris*, photosynthesis and respiration in, effect of culture filtrates, 457.

## Chlorethane feeding to bulls, results, 90.

## Chloroacetonitrile, toxicity against confused flour beetle, 505.

*Chlorochroa*—

- ugata* studies, Tex. 78.
- on cotton, control by dusts, 504.
- sayt, see Stinkbug, Say.

## Chlorophyll(s)—

- a and b, analysis of plant extracts for, 731.
- concentration, new method for determining, 150.

## Chloropicrin—

- as disinfectant for plant beds, 345.
- as factor in mobilization of soil nutrients, 738.
- for control of fungi in mushroom soil, 355.

## Chlorosis—

- in citrus, Tex. 60.
- in cowpeas, relation to sulfur, Tex. 60.
- in strawberry, Tex. 60.
- of macadamia seedlings, relation to chemical constituents of seeds, 636.
- of peach leaves, cause, 631.

**Chocolate—**

- coating conservation, 241.
- effect on inhibiting growth of staphylococci, 408.
- ice cream coatings, substitutes for coconut oil in, 675.
- milk, bacteriological study, 675.
- milk in dairy industry, 520.

**Choline—**

- deficiency in rats of various ages, 554.
- determination, modified methods for, 433, 434.
- dietary, effect on liver lipids of rats, 703.
- in milk, determination, 7.
- lipotropic action, relation of B vitamins and dietary fat to, 555.
- metabolism, 279.
- nutritional importance, 133.
- paper on, 705.
- significance as dietary factor, 133.
- structural specificity in transmethylation, 702.

Chondrodystrophy, hereditary, in fowl, 468.

Choriomeningitis, lymphocytic, transmission by arthropods, 384.

*Chorisagrotis auxillaris*, see Cutworm, army.

Christmas trees as farm crop, Mo. 47.

**Chromosome(s)—**

- degeneration, relation to growth and hybrid vigor, 467.
- handling, 607.
- in foxes, 319.
- variations, centrifugation as cause, 180.

**Chrysanthemum—**

- diseases, control by propagating practices, N.J. 358.
- Septoria* leaf blight, insoluble coppers for, Ohio 344.
- Verticillium* wilt, control, Ohio 344.

Chrysobothrini, North American species, revision, U.S.D.A. 228.

**Chrysobothris—**

- femorata*, see Apple tree borer, flat-headed.
- species, revision, U.S.D.A. 228.

*Chrysomphalus anidum*, see Red scale, Florida.

Chufas, hogging off, Ga. Coastal Plain 373.

Church, community, as sociological form in New York, 845.

Chytrid genera, new, 486.

**Cider—**

- preserved by new method, Ohio 296.
- sparkling, bulk fermentation process for, 442.

Cider-apple jelly, preparation, 11.

Cigarette smoking, immediate effect on basal metabolic rates, 570.

*Cimea lectularius*, see Bedbug.

**Cinchona—**

- culture, P.R. 628.
- drug plant chemistry of, P.R. 579.
- production, and diseases as limiting factors, P.R. 649.

Cinnamon, Ceylon and Malaya, culture, P.R. 628.

*Cirphis unipuncta*, see Armyworm.

**Citric acid—**

- effect on growth and calcium assimilation, 703.
- in pure solutions and in milk, determination, 731.

Citricola scale and parasites, biological notes, 790.

**Citrus—**

- and peach, comparative transpiration rates, 338.
- areas in Florida, production credit, Fla. 119.
- brown rot gummosis, 494.
- bud variants in, diploid-tetraploid periclinal chimeras as, 748.
- decline in New South Wales, cause, 648.
- dry root rot disease, control, 215.
- feeds, digestibility, 234.

fruit(s)—see also specific kinds.

Florida, juice color and quality of varieties, 197.

Florida, magnesium deficiency in, early diagnosis, 197.

juices, ascorbic acid and sulfur dioxide determination in, 294.

pulp, ensilage of, 232.

thiamin and riboflavin in, 856.

groves, plant bugs in, control, 503.

insects incidence, Tex. 73.

intakes, liberal, studies, 703.

juice, mineral composition, effect of soil treatment, 197.

leafhoppers, lime-zinc spray as repellent for, 75.

leaves, kerosene oil deposit on, determination, 74.

magnesium deficiency, early diagnosis, 494.

orchard, nocturnal wind-velocity, eddy-stability, and eddy-diffusivity in, 593.

orchards, control of brown snail in, 72.

pectin, recovery, effect of ethylene treatment, 297.

*Phytophthora* root rot in New South Wales, 494.

pruning-wound protectants, Tex. 60.

pulp, dried, for fattening beef cattle, Tex. 86.

pythiaceae fungi on, Calif. 495.

**red mite—**

effect of leaf age and feeding injury, 512.

effect of sulfur dust, 77.

population increase, effect of inert deposits of sprays, 83.

rust mites, population studies, Tex. 73.

stem-end rot, Tex. 60.

thrips, biology, 72.

thrips rearing in laboratory, 74.

thrips resistance to tartar emetic, 499.

trees, coastal, manganese and zinc deficiencies in, 215.

## Citrus—Continued.

trees, effects of applications of tartar emetic on, 795.

varieties for rootstock purposes, seed production and seedling yields, 635.

variety tests, Ga.Coastal Plain, 331.

waste liquors, alcohol from, U.S.D.A. 723.

*Cladis nitidula*, control of scale insects by, P.R. 655.

*Cladosporium*—

*fulvum*, new tomato variety developed for resistance to, Mass. 49.

sp., new form causing tomato leaf blight, Ohio, 344.

## Clam(s)—

analyses, Me. 545.

razor, qualities, effect of canning, freezing, and storage, Oreg. 579.

Clavacin, an antibacterial substance, production, 26.

*Claviceps yanagawaensis* in imported seed of Japanese lawngrass, 62.

## Clay(s)—

colloidal, composition, 301.

loam, Dunkirk silty, structure, relation to pF moisture measurements, 161.

montmorillonite in, semiquantitative estimation, 7.

particles, study with electron microscope, 301.

soils, stability, 160.

Clear Lake gnat, flight and oviposition habits, 81.

Clemson College notes, 869.

Click beetles, biology, 654.

Climate(s)—see also Meteorology.

and injurious insect studies, Kans. 655.

of California, types, 14.

of southwest Guatemala, 159.

Climatological data, 14, 299, 593.

Climatological data, 1911-1940, for Wind River Weather Station, Wash., U.S.D.A. 594.

## Climatology—

in service of agriculture, U.S.D.A. 298.

physical, treatise, 443.

*Clostridium*—

*acetobutylicum*, fermentation of Jerusalem-artichokes by, 431.

*butylicum*, cell-free preparations, dissimulation of pyruvic acid by, 309.

residue, pig feeding experiment with, 376.

*sordellii*, recovery from cattle and sheep, 679.

sp., fermentative decomposition of purines by, 583.

Cloth strength testing, 422.

Clothes moth, webbing, in insect nests, 73.

## Clothing—

and fabrics, conservation, U.S.D.A. 716.

for women, U.S.D.A. 716.

for women and children, performance during wear, R.I. 425.

make-overs from men's suits, U.S.D.A. 718.

## Clothing—Continued.

planning for farm family, Miss. 718.

standards, British, as result of rationing program, 425.

supplies, minimum, Miss. 424.

supplies of socially participating white farm families, Miss. 424.

## Clover—

alsike—

nectar, relation to relative humidity, 72.

nutrients in, effect of soil fertility, Ind. 737.

cluster, apparent digestibility of, 797.

crimson, growing seed of, Miss. 326.

crimson, response to boron with and without lime, 598.

fertilizer tests, R.I. 326.

for pasture and hay, seeding practices and seeds, N.J. 187.

inoculation, mixing artificial cultures with cottonseed meal or sand for, U.S.D.A. 617.

Ladino, promising legume in coastal plain pastures, N.C. 473.

Ladino, use as orchard cover crop, Pa. 628.

red—

breeding, Pa. 619, U.S.D.A. 618.

diseases in Wisconsin, U.S.D.A. 640.

hays of widely varying phosphorus content, availability to rats of phosphorus in, 85.

lime, P, and K needs, N.C. 473.

nutrients in, effect of soil fertility, Ind. 737.

seed stocks, differences in control field behavior, N.Y.State 186.

seed production tests, Pa. 619.

subterranean, leaf rust, reaction of varieties to, 772.

superior varieties or strains grown by station, Oreg. 619.

variety tests, Alaska 617, Miss. 186, 325, Tex. 42.

white—

disease studies in Alabama, 484.

diseases responsible for crop failure, 350.

genetics of self-compatibility in, 748.

importance in bluegrass pasture, Pa. 619.

mineral content of clones, grown on different soils, 759.

yields, crop rotation v. superphosphate for, Ark. 755.

*Cnidioscolus macrogravii*, new source of oil in Bahia, Brazil, 740.

## Coal tar—

fractions as wood preservatives, 255.

products for insecticides, Pa. 652.

Cobalt, absorption and excretion by man, 279.

Coccarboxylase, paper on, 705.

## Coccidia(um)—

intestinal, of rabbit, life cycle, 823.

new species pathogenic for chickens, 686.

*Coccidioides immitis*—

intranasal and intraperitoneal infection of mouse with, 677.

isolation from wild rodents and relation to coccidioidomycosis, 524.

Coccidioidomycosis in wild rodents, determining extent of endemic areas, 823.

## Coccidiosis—

avian, chemotherapy in control, 814.

cecal, acquired resistance in chickens to, effect of sulfaguanidine on, 531.

experimental bovine, sulfaguanidine therapy in, 819.

in California valley quail during captivity, reducing, 251.

in cattle, U.S.D.A. 98.

in cattle and feed lot lambs, Mont. 676.

in chickens, 531, U.S.D.A. 98, Wis. 248.

in chickens, periodicity of oocyst discharge in, 248.

in sage grouse not transmissible to chickens, 531.

resistance by chickens, sulfaguanidine as prophylactic during period of acquirement, 826.

studies, Oreg. 676.

*Coccophagus fuscipes*, effect of dormant sprays on, 511.

*Coccus pseudomagnoliarum*, see Citricola scale.

*Cochliomyia americana*, see Screwworm.

*Cochliomyia macellaria*, see Screwworm, secondary.

*Cochlosoma rostratum* from turkey, 251.

## Cocks—

hormonal induction of "broodiness" in, 377.

phospholipids of plasma, effect of diethylstilboestrol on, 802.

## Cockerels—

fertility in, Mo. 322.

head appendages, effect on size of testes, 323.

semen production, seasonal variation, 377.

White Leghorn, effect of sunlight, dubbing, and fractionated anterior pituitary extract on, 613.

## Cockroach(es)—

## American—

and German, relative resistance to pyrethrum spray, 782.

effects of infrared irradiation, 786. fecundity, longevity, and parthenogenesis, 221.

nymphal development, 502.

riboflavin metabolism in, study of fluorescence microscopy, 658.

toxicity of sodium fluoride for, 365.

control, Nebr. 73.

development, effect of temperature, 222.

German, action of pyrethrum on, 786.

German, circulation of hemolymph in wings, 365.

poison, compound 4,6-dinitro-o-cresol as, 503.

## Cockroach(es)—Continued.

sprays, new method of testing, 222.

v. pyrethrum, 221.

## Cocoa—

cake meal, feeding value for pigs, 376.

fillings, effect on inhibiting growth of staphylococci, 408.

Coconut oil, substitutes for in making dipping chocolate, 241, 675.

## Codling moth—

activity, effect of warm spring evenings, N.C. 499.

advance in British Columbia, 500.

biological control in South Africa, 506.

biology and control, Kans. 655.

combination sprays for, 782.

control, calyx spray in, 660.

control, developments in, 363.

control, efficiency of nicotine sprays for, 80.

control in British Columbia, 369.

control, studies, Vt. 506.

control, varietal interplanting in, 660.

damage, reducing to 3 percent, 225.

larvae, killing with low temperatures, 72.

larvae, newly hatched, toxicity of nicotine compounds to, 792.

larvae, overwintering, sprays for killing, 72.

larvae, toxicity of acid amides and their N-substituted derivatives to, 498.

larvae, toxicity of sulfanilamide and related compounds to, 498.

larvae, transforming, refrigeration test, 498.

new species of *Ephialtes* parasitizing, 510.

ovicidal value of light mineral oils, 360.

oviposition in mixed pear orchard, 506.

sprays, making effective, 363.

sprays, spreaders for, 792, N.Y.State 785.

spring brood, emergence and subsequent worm entry, time relations, 792.

studies, 219, 225.

supplementary control measures for, Va. 506.

toxicity of synthetic organic chemicals to, 782.

Cod-liver oil and egg oil, comparative rates of absorption of, 702.

*Coelophora inaequalis*, establishment, P.R. 655.

Coenzyme R, vitamin H, and biotin, review of literature, 863.

*Coffea arabica*, root system, studies, P.R.U. 198.

## Coffee

"cock's-eye" disease, 778.

flowers, essential oils from, studies, P.R. 579.

grounds in animal rations, 285.

scale insects in Puerto Rico, relation to ants and other organisms, P.R.U. 223. varieties, P.R. 628.

Coffee-sugar tablets for the Army, U.S.D.A. 723.

- Colamine, effect on growth and protoplasmic streaming in oats, 742.
- Colchicine—  
 effects on cell division, 746.  
 technic and results of induced polyploidy in black gram, 179.  
 tetraploid tomato plants induced by, 179.
- Colchicum* susceptibility to colchicine, 463.
- Coleophora malivorella*, see Pistol case-bearer.
- Coleoptera, elm bark infesting, larval characteristics, 228.
- Colliform organisms and *Ericinia* spp., relation, 599.
- Collard breeding, Ga. 627.
- Colletotrichum*—  
*capsici*, saltation in, 847.  
*destructivum* isolates, variations in sporulation, 769.
- Colloid(s)—  
 science, advances in, 149.  
 soil, deferrated, flocculation and electrokinetic behavior, 723.
- Colloidal—  
 clay composition, 301.  
 material in Missouri soils, properties, Mo. 15.  
 systems of soil, significance of Donnan equilibria for, 452.
- Color names, central notations of ISCC-NBS, 140.
- Colorado College notes, 427, 721.
- Colorado Station notes, 427, 721.
- Colts—  
 draft, growth in, Mo. 84.  
 colter in, prevention with iodized salt, Mont. 676.
- Combine harvesters in Missouri, Mo. 105.
- Commodities, domestic distribution, transportation, and storage, U.S.D.A. 841.
- Commodity Credit Corporation—  
 report, U.S.D.A. 841.  
 stabilization operations, 393.
- Commodity output, regulating, via multiple prices, 693.
- Community(ies), see also Rural community(ies).  
 organization and adult education, 845.  
 organization for war and for peace, 406.
- Comperiella bifasciata*—  
 effect of tartar emetic on, 77.  
 oriental races in California, comparison, 664.  
 parasite of California red scale, 796.
- Complement fixation with neurotropic viruses, 816.
- Compost heaps, decomposition, changes in organic matter during, 597.
- Concrete—  
 canal lining cured by sprayed coats of white-pigmented compound, 392.  
 with minimum of steel, 689.
- Conifer(s)—  
 crown gall, 359.  
 newly transplanted, effect of wax emulsions on, Kans. 628.
- Conifer(s)—Continued.  
 plantations, competition in, Vt. 56.  
 seed germination studies, N.Y.State 200.
- Connecticut [New Haven] Station notes, 427.
- Conotrachelus*—  
*nenuphar*, see Plum curculio.  
 sp. on partridge pea, Ga. 654.
- Conservation practices as weapons of war, Okla. 693.
- Consumer education course for secondary schools, 543.
- Consumption in Britain, control of, 693.
- Cooperation, see Agricultural cooperation.
- Cooperative(s)—  
 associations, principal types of egg and poultry handling by, Ohio 394.  
 cotton gin associations, organization and operation, N.Mex. 120.  
 elevator associations, percentages of members and directors that were tenants, Tex. 111.  
 requirements for, N.Dak. 693.
- Cooperia* spp., percentage incidence in cattle, 101.
- Coot, American, parasites, 217.
- Copper—  
 arsenate, basic, status as insecticide and fungicide, 782.  
 arsenate, determination in treated wood, 154.  
 chromate, determination in treated wood, 154.  
 deficiency in ewes and stringy wool, 86.  
 deficiency in plants, 60.  
 dusts, performance, effect of inert ingredients, 484.  
 effect on lipase activity in Cheddar cheese, 813.  
 fungicides, compatibility with nicotine bentonite insecticides, 364.  
 fungicides, fixed, adherence, effect of spray supplements, 346.  
 intake, effects on cattle, 527.  
 sprays, substitute for bordeaux, value against blight, Pa. 641.  
 substitutes in fungicidal sprays, 206.  
 value on soils in southeastern North Carolina, N.C. 446.
- Coryra cephalonica* on milled rice, U.S.D.A. 73.
- Cork substitutes from residues, U.S.D.A. 723.
- Corn—  
 absorption of selenium by, from *Astragalus* extracts and solutions containing proteins, 173.  
 albino, culture, 171.  
 and corn smut tumors, auxin extraction from, 61.  
 and hog supplies and prices, control, U.S.D.A. 111.  
 and sorghums and effects on succeeding crops, comparisons, Tex. 42.  
 bacterial wilt resistance, bacteriophage sign of, Ohio 344.  
 Belt hybrids, poor adaptation, N.C. 473

## Corn—Continued.

- bins, insects in, fumigating mixture tests, 502.  
 biological value for dairy heifers, 90.  
 borer, European—  
   alternative insecticide for, N.Y.State 785.  
   control, Conn.[New Haven] 499, 507.  
   effect on reduction in corn yield, 507.  
   in East North Central States, U.S.D.A. 80.  
   in Iowa, 783.  
   infestation, effect of growth stage of sweet corn, 782.  
   nutrition studies, synthetic food media for use in, 508.  
   on resistant and susceptible field corn, survival, weight, and location, 792.  
   protecting market sweet corn from, U.S.D.A. 226.  
   regression of in Quebec, 782.  
   studies, Ohio 362.  
 borer, southwestern—  
   in sweet corn, Kans. 655.  
   outbreak in Kansas, 783.  
 breeding, Ga.Coastal Plain 325, Kans. 618, Miss. 186, Mo. 41, Mont. 618, Nebr. 41, Ohio 326, Tex. 42, U.S.D.A. 616.  
 canned, production of staphylococcus enterotoxin in, 409.  
 charcoal rot, Nebr. 59.  
 composition, factors affecting, 21.  
 culture tests, Ga.Coastal Plain 325, Kans. 618, Miss. 325, Mont. 619, Tex. 42.  
 dehydrator for, Colo. 849.  
 dent, resistance to *Diplodia zeae*, nature of, 487.  
*Diplodia macrospora* leaf spot, U.S.D.A. 58.  
 diploid, shoot apex and growth pattern of leaf blade, developmental relation, 747.  
 diseases in Maryland, U.S.D.A. 203.  
 dried distillers' byproducts in laying rations, 377.  
 ear, ventilation of in metal cribs, Ohio 535.  
 ears, number necessary for adequate sample at harvesttime, 621.  
 earworm—  
   control by birds, 369.  
   control, mineral oil treatment, U.S.D.A. 226.  
   hibernation, U.S.D.A. 793.  
   in sweet corn, control, 660, Ark. 783, Kans. 655.  
   studies, 73, Mont. 655, Nebr. 73, Tex. 78.  
 effect of hormone treatments, Miss. 018.  
 efficiency of tillage methods for, Mo. 41.  
*Euchlaena*, and *Tripsacum*, genetic and cytological relations, Tex. 42.

## Corn—Continued.

- fertilizer placement experiments, Mo. 41.  
 fertilizer requirements, predicting, plant tissue tests v. soil tests, 185.  
 fertilizer tests, Ga. 617, Ga.Coastal Plain 325, Kans. 618, Miss. 325, Tex. 42.  
*Fusarium moniliforme* infection, effect of seed treatments, Mo. 59.  
 futures, volume of trading, open contracts, and prices, U.S.D.A. 123.  
 genetic studies, Mo. 41.  
 grain, yellow, carotenoids of, 435.  
 grain, yellow carotenoids of, spectrophotometric determination, 436.  
 ground, as preservative for legume silage, Ohio 880.  
 growth in, effects of translocation, 747.  
 harvesting with hogs, Nebr. 41.  
 heat, light, and drought tolerance in, Kans. 618.  
*Helminthosporium* leaf blight of, U.S.D.A. 203, 640.  
*Helminthosporium turcicum* leaf blight, unusual amount of damage by, U.S.D.A. 58.  
 hogging off, Ga.Coastal Plain 373.  
 hybrid(s)—  
   adapted to Utah, Utah 620.  
   and open-pollinated varieties, tests, Pa. 619.  
   and varieties, yields, Miss. 755.  
   development for Arkansas, Ark. 40.  
   for silage, yields and time to harvest, Ill. 475.  
   for victory and for profit, W.Va. 473.  
   locally developed, superiority, N.C. 473.  
   production, Iowa 608.  
   production of own seed by farmers, N.C. 473.  
   resistant to fungus diseases, development, Ohio 344.  
   seed, disease infection, 484.  
   tests, Miss. 618.  
 inbred lines, convergent improvement with, 748.  
 inheritance studies, Tex. 42.  
 interplanting with legumes, Miss. 326.  
 kernels, auxin in during ontogeny, from plants of varying heterotic vigor, 742.  
 leaf aphid, notes, Mont. 655.  
 leaf blight severe in Virginia, U.S.D.A. 343.  
 leafhopper extract, sugarcane stem galls induced by, 502.  
 lepidopterous pests in Trinidad, 661.  
 morphological characters, use in forecasting yield, 760.  
 mutants, association with homozygous deficiencies, 178.  
 new hybrids ready for farm trial, Ohio 326.  
 nutrients in, effect of soil fertility, Ind. 737.  
 open-pollinated v. hybrid, for brood sows, Mo. 84.

## Corn—Continued.

- origin, 25.
- origin, western Guatemala a secondary center, 177.
- plant juice, ovulating factor in, 91.
- plants, young, response to phosphates differing in solubility, 21.
- prehistoric, from Cañon del Muerto, 621.
- production, mechanical equipment, power, and labor for, Nebr. 105.
- protection from weevils, Miss. 409.
- Pythium* stalk rot, 772.
- reduction in yield by European corn borer, 507.
- residual effects from different levels of fertilizer, R.I. 326.
- response to fallow and other tillage practices, Nebr. 41.
- roasting, variety tests, Ga.Coastal Plain, 331.
- roots, lithium chloride toxicity in meristem cells, cytological studies, 317.
- rootworm, southern, in sweet corn, Kans. 655.
- rootworm, southern, studies, Ga. 654, Nebr. 73.
- rotation experiment, N.H. 187.
- sap beetle in rice, life history, 361.
- sap beetle on milled rice, U.S.D.A. 73.
- seed-borne micro-organisms, N.Y.State 203.
- seed, response to hormone treatment, N.Y.State 190.
- seed stocks offered for sale to New York farmers, merits, N.Y.State 186.
- seed treatment, effect on yield, Mo. 41.
- seedlings grown from X-rayed seeds, root modifications induced in, 170.
- shoot, developmental anatomy, 316.
- silage, *see* Silage.
- silks, receptiveness in, duration, 621.
- sirup, enzyme-converted, use in manufacture of bulk sweetened condensed milk, 674.
- sirup solids in ice cream, 240.
- smut resistance in hybrids, breeding for, 62.
- soil improvement crops for, Miss. 326.
- storage, studies, Ohio 392.
- substitutes for fattening cattle, protein supplements as, 513.
- sugar, new antiseptic agent from, U.S.D.A. 728.
- superior varieties or strains grown by station, Oreg. 610.
- sweet, *see* Sweet corn.
- varieties, Mich. 755.
- varieties and hybrids, relative performance, Ark. 755.
- varieties, growth curves, 603.
- variety tests, Ark. 755, Ga. 617, Ga.Coastal Plain 325, Kans. 618, Miss. 186, 325, Mo. 41, Mont. 618, Nebr. 41, Okla. 755, R.I. 326, Tex. 42.
- vitamin B<sub>1</sub> treatment, Kans. 618.
- waxy, starch from, U.S.D.A. 723.

## Corn—Continued.

- waxy starch from, possible competitor for tapioca, 456, U.S.D.A. 617.
- whole kernel, frozen, determining maturity of, 150, 151.
- winter cover and green manure crops for, Ga.Coastal Plain 325.
- world production and trade, U.S.D.A. 123.
- yellow, storage, relation to vitamin A deficiency, U.S.D.A. 605.
- yields, crop rotation v. superphosphate for, Ark. 755.
- yields effect of green manure, Ark. 755.
- yields, high, from better hybrids and adapted varieties, Miss. 618.
- yields in western Iowa, effect of rainfall distribution and temperature, 621.
- yields, increase by turning under legumes, N.C. 473.
- Cornell University notes, 143, 429, 869.
- Cornstalk borer, lesser, studies, Ga. 655.
- Cornstalks—
  - handling for conversion into artificial manure, Mo. 105.
  - use in soil building, Mo. 15.
- Cornus sericea*, taxonomic study, 461.
- Corpus luteum and follicle, method of growth in mouse ovary, 753.
- Corticium stevensii*, pure cultures, obtaining from sclerotia, 60.
- Corynebacterium*—
  - pyogenes* infection in cattle, abscess due to, 527.
  - recommended change of *Phytomonas* spp. to, 204.
- Coryneliaceae, revisionary studies, 311.
- Coryneum longistipitatum* development and fruiting, effect of temperature, 485.
- Coryza—
  - bacillus, hemophilic fowl, superior medium for, 824.
  - infectious, R.I. 384.
  - infectious, prevention and treatment with sulfathiazole, 386.
- Cotton—
  - and linen mixtures, analysis of linen in, 863.
  - angular leaf spot control, 484, Tex. 59.
  - aphid control, 361, 654.
  - aphid control, calcium arsenate with and without aphicides for, 362.
  - aphid control, effect on cotton yield, 363.
  - aphid control, insecticide tests for, 501, 502.
  - aphid control, rotenone with calcium arsenate for, 366.
  - aphid development, relation to fertilizers, 366.
  - aphid, effect of insecticidal drift in small plots, 361.
  - aphid studies, Ark. 72.
  - areas, soil losses and yields from, effect of compost, woods litter, and manure, N.C. 446.
  - Asiatic, anthocyanin pattern in, 606.

## Cotton—Continued.

- boll rots and fungi associated with them, U.S.D.A. 640.
- breeding, Ga. 617, Ga.Coastal Plain 325, Miss. 325, Okla. 755, Tex. 42, U.S.D.A. 616.
- breeding for strength, N.C. 473.
- breeding, recent developments in, improvements resulting, N.C. 473.
- breeding, relation to taxonomy, 25.
- culture tests, Tex. 42.
- cytogenetics of, Tex. 42.
- disease(s)—
  - control, 485.
  - of Argentina, 643.
  - seed-borne, fungicide tests against, 209.
  - seedling, and wilts and nematodes, Miss. 203.
  - survey, U.S.D.A. 640.
- dress prints, analysis of qualities, 865.
- effect of hormone treatments, Miss. 618.
- farmers, use of credit by, Tenn. 120.
- farms, improvement of low incomes on, N.C. 537.
- fertilizer for maximum profits, rate and analysis, Miss. 618.
- fertilizer placement for, Ga.Coastal Plain, 325.
- fertilizer requirements, predicting, plant tissue tests v. soil tests, 185.
- fertilizer tests, Ga. 617, Ga.Coastal Plain 325, Miss. 325, Tex. 42.
- fiber, cellulose determination in, 290.
- fiber quality, effect of water relations within plant, N.C. 473.
- fibers, number of, determined by growing conditions at blooming, N.C. 473.
- fla hopper—
  - control, 654.
  - control in Louisiana, La. 362.
  - host relation, 228.
  - insecticide tests for control, 501.
  - predator on, 72.
  - studies, Ark. 72, Tex. 73.
- foliar hydration in, 605.
- gin associations, cooperative, organization and operation, N.Mex. 120.
- ginning costs in North Carolina, N.C. 402, 537.
- ginning services in South Carolina, quality, S.C. 402.
- growth on Delta soils, variation of fertilizer needs for, Miss. 454.
- hairy vetch as green manure crop for, 185.
- improved American Egyptian, U.S.D.A. 616.
- improved varieties, variation of fiber diameter in, N.C. 473.
- in rotation with peanuts, K needs of, N.C. 473, U.S.D.A. 617.
- in rotation with soybeans, less N in, U.S.D.A. 617.
- infection from acid delinted treated seed v. untreated fuzzy seed, Tex. 59.

## Cotton—Continued.

- inheritance of perigynous heterotaxy and associated characters, 185.
- inheritance studies, Tex. 42.
- insects, hemipterous, control by dusts, 504.
- insects, studies, Ga. 654, Ga.Coastal Plain 362.
- irrigation tests, Calif. 328, Tex. 42.
- leafworm control, 654.
- leafworm, predator on, 72.
- leafworm studies, Ark. 72.
- leaves, mineral content, diurnal variations in, 744.
- leaves, withdrawal of water from fruit by, 30.
- lightning injury, 772.
- limed to different pH levels, minor elements for, Ga. 617.
- lint, for smokeless powder, U.S.D.A. 723.
- longer staple, breeding, Ark. 755.
- marketing in selected local markets, La. 121.
- marketing study, Ga. 693.
- mechanical harvesting, Tex. 105.
- N and K top dressings for, Ga.Coastal Plain 325.
- novel defense uses for, U.S.D.A. 723.
- nutrition studies, Ga. 617.
- of Oklahoma in wartime, production v. military requirements, Okla. 261.
- or boll weevils, U.S.D.A. 228.
- partition of mineral elements in, 605.
- pests, effect of arsenicals on, 361.
- pests, migration and control, 218.
- plant(s)—
  - asynaptic, and their polyploids, 467.
  - composition and uptake of nutrients at different growth stages, Ga. 760.
  - food requirements, Ark. 40.
- planter and fertilizer distributor, description, N.C. 534.
- prematurely killed by cotton root rot, yield and quality, effect of insect control on, 218.
- processing, for military uses, U.S.D.A. 723.
- produced in Oklahoma in 1941, quality, Okla. 261.
- quality, increase, N.C. 473.
- replacing imported fibers with, U.S.D.A. 723.
- residual effect of cotton burs and manure for, Tex. 42.
- response to fertilizers, correlation of chemical soil tests with, Ga. 595.
- root rot—
  - caused by *Thielaviopsis basicola*, 62.
  - control, U.S.D.A. 347.
  - effects of cropping and cultural treatments, 484.
  - studies, Tex., 59, 208.
- roots, cell proliferation and protoxylem differentiation in, effect of L-proline, 463.

## Cotton—Continued.

roots, distribution, effect of soil preparation, Miss. 186.

roots, root pressures and injury to by cultivation, 185.

rotating with close growing crops, value, 184.

row width experiments, 760.

## sea-island—

culture on Coastal Plain, Ga.Coastal Plain 188.

new strains of, U.S.D.A. 616.

production, development, Ga.Coastal Plain 325.

secondary nutrient elements for, Ga.

Coastal Plain 325.

seed, *see* Cottonseed.

seedlings from reginned and acid-delinted seed, increase of, N.C. 473.

soil improvement crops for, Miss. 326.

sources of P for, with and without gypsum, Ga. 617.

strength tests, Miss. 325.

textiles, moisture in, volumetric determination, 572.

utilization of absorbed phosphate by, 453.

varieties adapted to mechanical harvesting, Tex. 42.

varieties, new, importance of seed purity in, N.C. 473.

varieties, reactions to strains of *Fusarium* wilt fungus, Ark. 59.

varieties, spinning tests, Okla. 756.

varieties, strength differences in, estimating, 185.

variety tests, Ga. 617, Ga.Coastal Plain 325, Miss. 186, 325, Mo. 41, Okla. 755, Tex. 42.

variety-wilt-tests, regional, Ga. 617.

*Verticillium* wilt, U.S.D.A. 640.

vetch and other green manures for, Tex. 42.

wilt and root knot resistant varieties, Tex. 59.

wilt in Alabama, 63.

wilt-resistant varieties best control for wilt, N.C. 473.

winter cover and green manure crops for, Ga.Coastal Plain 325.

yield after green manures and sorghums v. commercial N, Miss. 326.

yield, effect of boll weevil and cotton aphid control, 363.

yield, effect of green manure, Ark. 755.

yield, increasing by disease control, Ark. 769.

## Cottonseed—

and fertilizer, efficiency in distribution and placement, Tex. 105.

cake v. corn in fattening ration for calves, Miss. 86.

diseases, transmission, 484.

disinfection in wartime, 208.

dusting, effect on emergence of seedlings in *Rhizoctonia* infested soil, 642.

## Cottonseed—Continued.

fuzzy and acid-delinted, effect of depth of planting, 484.

germination, effect of soil disturbance and machine placement of fertilizer, Tex. 328.

improvements in cultural practices, U.S.D.A. 617.

in storage, quality elements, effect of artificially drying seed cotton, U.S.D.A. 43.

## meal—

ash as fertilizer, 168.

feeding, effect on milk properties, 808.

in large quantities for pigs, Miss. 86.

in place of corn for milk production, Okla. 808.

new grade authorized, Tex. 373.

profitable supplement to reeds for finishing yearling steers, N.C. 514.

replacement value in good dairy ration, 519.

moisture in, relation to germinability and presence of *Aspergillus wentii*, 487.

more effective materials for treating, N.C. 473.

rate of application of Ceresan to, U.S.D.A. 640.

treated and untreated anthracnose-infested, comparison, Ga. 617.

treated with growth substances, root initiation by seedlings from, Tex. 42.

treatment for anthracnose control, Mo. 59.

treatment for seedling blight and boll rot, Ark. 59.

treatment tests in 1941, results, 484.

treatment with dust preparations, 484.

treatment with fungicides, 208.

treatment, studies, 484, Okla. 769.

Cottonwood protein for adhesives, Miss. 154.

Counter, electric, for consecutive counting of small objects, 317.

Country, *see* Rural.

Covariance analysis by method of individual comparisons, 669.

## Cover crop(s)—

growth, phosphorus and potash, needs to maintain, Pa. 628.

seed production, Oreg. 619.

winter, culture experiments, Ga.Coastal Plain 325.

winter, variety tests, Ga.Coastal Plain 325.

Cover-glass preparations, staining rack for handling, 317.

Cow(s)—*see also* Cattle and Helpers.

beef, finishing and wintering rations, Miss. 231.

## dairy—

artificial insemination in, Mo. 34.

**Cow(s)—Continued.****dairy—continued.**

effect of sulfanilamide administration, 681.

irrigated pasture for, 807.

oat and pea silage as substitute for cured hay, Alaska 666.

rations, minerals and vitamins in, Miss. 238.

Hereford beef, pastures for wintering and breeding, Ga.Coastal Plain 372.

improvement in breeding and fertility by ascorbic acid administration, 35.

irradiation, effect on milk, Ohio 380.

lactating, rations for, Tex. 92.

limited-grain feeding and all-year pasture for, Tenn. 238.

manure as source of vitamins for chicks, 518.

milk production, *see* Milk production.

ovulation, relation to oestrus, 183.

udders, *see* Udder.

wintering, pea vine silage, alfalfa hay, and wild hay for, Oreg. 666.

**Cowpea(s)—**

breeding, Tex. 42.

cultural tests, Miss. 186.

curculio, studies, Ga. 654.

diseases, Ga. 640.

fertilizer tests, Ga. 617.

mineral content, effect of environment, Ga. 699.

plants, variations in ascorbic acid and dry matter at different times of day, 313.

root knot susceptibility, Tex. 60.

root-nodule production, relation to sulfur, Tex. 60.

variety tests, Ga.Coastal Plain 325, Kans. 618, Miss. 325.

Crab apples, French, selection of cold-resistant seedlings, Kans. 628.

Crab meal, nutritive properties and use, 377.

**Cranberry—**

growth and fruiting, 340.

storage, lower temperature tests to reduce loss, 190.

Crayfish meal, nutritive value, 231.

**Cream—**

analyses, Me. 545.

bacteriological examination methods compared, 674.

churning, pasteurization, developments in, 239.

free fatty acids in, effect on butter quality, 808.

freezing for storage, 239.

frozen, as source of fat in ice cream, Mich. 675.

frozen, storage, 807.

frozen, used in ice cream, reducing oiling off, 241.

grading study, 807.

mold in, 807, 808, Okla. 808.

mold mycelia growth in, treatments affecting, 91.

**Cream—Continued.**

quality in, counts of mold mycelia for, Ark. 797.

quality, relation to bacteria from water sources, 239.

refrigerated and pasteurized, development of positive phosphatase test on, 91.

supply, farm, control of mold in, Ark. 96.

variously treated, keeping quality, 91.

visual mold test for under Kansas conditions, 812.

**Creamery(ies)—**

cooperative in South Dakota, S.Dak. 269.

water supplies, bacteriological studies, 92, 380.

Creatine formation in chicks, 237.

Credit bureaus from consumer's point of view, 718.

*Crepis* species, cytological methods for, 607.

Cress, hoary, root system, Kans. 618.

Cricket, Mormon, control, Mont. 655.

*Cronartium ribicola*, *see* White pine blister rust.

Crop(s)—*see also* Forage crops and specific kinds.

and fruit tree responses on phosphate-deficient soil, 631.

canning, diseases, survey, N.Y.State 203.

canning, seed decay, damping-off, and root rot, effect of environmental conditions, N.Y.State 203.

disease-resistant, breeding, 203.

effects on succeeding crops, R.I. 326.

equipment investment and crop acres, relation, Mo. 110.

forecasts of good harvest for, Miss. 142.

growing days at Tifton, Ga.Coastal Plain 299.

grown on North Carolina soils, effect of vitamin B<sub>1</sub> on, 619.

in Bulloch Co., labor and power needs on, Ga. 538.

in rotation, fertilizer tests, Tex. 42.

irrigated, yields, effect of manure, alfalfa, and pastured sweetclover on, Nebr. 41.

irrigation tests, Okla. 756.

of Hawaii, boron in, 24.

ornamental greenhouse, growing in gravel culture, Ohio 341.

plants, resistance to insect attack, Kans. 655.

production, increase by conservation measures, U.S.D.A. 396.

reports, U.S.D.A. 124, 540.

residues, use for soil defense, U.S.D.A. 24.

response to potash fertilization, relation to plant available potassium, 453.

rotation and sequence experiments, Tex. 42.

rotations, *see* Rotation of crops.

seedtime and harvest, U.S.D.A. 261.

vetch and other green manures for, Tex. 42.

**Crops(s)—Continued.**

- water requirements, determining by tensiometers, U.S.D.A. 594.
- yields and composition, effect of borax, 307.
- yields and day length, U.S.D.A. 607.
- Cropland, abandoned, regrassing, Mont. 619.
- Crotalaria spectabilis*—
  - canker disease associated with *Sclerotium*, U.S.D.A. 343.
  - immunity to root knot, U.S.D.A. 640.
- Crotalaria* variety tests, Ga.Coastal Plain 325.
- Crown gall—
  - tissue, autonomous bacteria-free, studies, 204.
  - tumors, secondary, bacteriological sterility of tissues derived from, 774.
- Cryolite—
  - as insecticide, La. 362.
  - larvicidal value, effect of lime and lime-sulfur on, 500.
- Cryptogams, carotenoid pigments of, 310.
- Crystal Lake, California, reclamation with rotenone, 658.
- Crystal violet, improved cytological methods with, 607.
- Crystallography and plant viruses, 204.
- Cube, toxicity to plant bugs, effect of additions of sulfonated oil on, 787.
- Cucumber(s)—
  - analysis, Mich. 850.
  - bacterial wilt, Ohio, 344.
  - beetle control, Mo. 72.
  - breeding for the South, 627.
  - culture, Mont. 628.
  - flower development and structure, effect of fertilization and pruning, Ark. 46.
  - genetics of, 627.
  - greenhouse, diseases, 491.
  - growth, effect of soil temperature, Mo. 46.
  - leaf disease control by Cu dusts, N.C. 485.
  - mosaic virus, resistance to, 66.
  - pests, studies, 218.
  - pickles, analysis, Mich. 850.
  - pickles, pasteurization, death rate of micro organisms during, 295.
  - production problems, symposium, 295.
  - seed stocks, tests, N.Y.State 191.
  - seed treatments, Tex. 59.
  - seedling damping-off resistance, relation to age, season, and N nutrition, 65.
  - spacing and fertilizer tests, Miss. 191.
  - varieties for greenhouse culture, development, Ohio 331.
  - variety tests, Ga.Coastal Plain 331.
- Cucurbit—
  - diseases, control, 484.
  - downy mildew, U.S.D.A. 58.
  - seeds and isolated cotyledons, gaseous exchange, 315.
- Culex tarsalis*—
  - encephalitis viruses from, 385.
  - vector of St. Louis encephalitis, 816.

- Culture change in southern Illinois, 697.
- Cupric chloride crystallization patterns, modification by traces of proteins, 580.
- Curinus* sp., control of scale insects by, P.R. 655.
- Curly top virus studies, U.S.D.A. 640.
- Current(s)—
  - diseases, control, N.Y.State 203.
  - golden, new source of carotene, 855.
  - leaf spot control with bordeaux spray, N.Y.State 215.
  - phosphorus and calcium in, 133.
- Curtain fabrics, glass, studies, Ohio 426.
- Curvularia lunata*, notes, Tex. 60.
- Cuscutas, new, from western North America, 360.
- Mustard and cream fillings, effect of ultraviolet radiation and ozone on bacteria in, 408.
- Cutter for spectroscopic electrodes, 6.
- Cutworm(s)—
  - army, notes, Mont. 655.
  - control, R.I. 362.
  - pale western, notes, Mont. 655.
- Cylas formicarius elegantulus*, see Sweetpotato weevil.
- Cylindrocarpon chrenbergii* on alfalfa and sweetclover, varietal resistance to, 349.
- Cylindrocopturus furnissi* on Douglas fir, 791.
- Cylindromyia porteri*, receipt of shipment of, P.R. 656.
- Cypripedium* fruits, intermittent growth, 33.
- Cystine—
  - estimation, colorimetric micromethod for, 558.
  - formation from homocysteine and serine by liver tissue of rats, 724.
  - formation from homocysteine by liver tissue, 724.
  - sulfur, enzymatic conversion of radioactive sulfide sulfur to, 727.
- Cystine—
  - added to casein diets, lactation-promoting properties, Ark. 284.
  - as supplement to all alfalfa hay ration for milk production, 93.
  - dietary, effect of liver lipids of rats, 703.
  - estimation, colorimetric micromethod for, 558.
  - relation to choline requirement of rats, 279.
  - synthesis in rumen of sheep, possibility, 234.
- Cytochrome c, quantitative determination, 589.
- Cytophaga* spp., notes, 305.
- Cytospora abietis*, cause of fir canker, 71.
- Dactylis glomerata*, variations in chromosomal association and behavior during meiosis, 747.
- Dactylum dendroides* in mushroom soil, control with chloropicrin, 355.
- Daedalia confragosa*, unusual development of fruit bodies, 27.
- Dahlias, variety test, Ga. 627.

**Dairy—**

cattle and dairy cows, *see* Cattle and Cows.  
farm(s)—

fertility needs of crops, N.H. 187.

income, factors affecting, Nev. 539.

use of electric power on, Utah 257.

glassware, checked for accuracy, N.Y. State 728.

herd, adequate and economic housing, 808.

manufacturing short courses, manual for, 383.

operations, applications of newer phosphates in, 520.

opportunity areas in New Hampshire, N.H. 539.

plants, efficiency of fat removal by, Vt. 520.

problems, overcoming, Mich. 808.

production, fly control, nitrogen, and silage studies affecting, Kans. 671.

products—

analyses, Me. 545.

concentration of dissolved oxygen in, method for measuring, 91.

consumption in metropolitan New Jersey, N.J. 842.

consumption, relation to quality, 807.

effect of water bacteria on quality, 238.

fats in, oxidative deterioration, U.S.D.A. 671.

fluorescent bacteria in, Mo. 92.

judging for flavor, sensory adaptation as factor, 92.

oxidized flavor, mechanisms of, 92.

production, increasing after the war, 796.

quality, path to, 520.

scoring, State-wide, summary, 520.

value in nutrition, 378.

quality improvement, organizing work of fieldman, 520.

rations containing grain, efficiency, Iowa 809.

rations, use of home-grown roughages in, Ga. 671.

sanitation, new frontiers in, 520.

sires, *see* Bull(s) and Sires.

Dairying—*see also* Creamery(ies), Butter, Milk, *etc.*

research, 808.

Damping-off—

control by use of sphagnum, N.J. 646.

in *Pinus resinosa*, chemical control, 651.

injury to seedlings, effect of drying soil on control, Pa. 628.

of broadleaf seedlings, Nebr. 59.

Dandelion, Russian, growing, progress in, Colo. 768.

Dark adaptation—

and blood plasma levels of vitamin A tests, comparison, 282.

and vitamin A, effect of alcohol, benzadrine, and vitamin C, 552.

Dark adaptation—Continued.

and vitamin A studies with biophotometer, 283.

measurements, for diagnosing vitamin A deficiency, 414.

measuring, comparison of methods, 283.

of children, relation to dietary levels of vitamin A, 709.

relation to vitamin A in blood, 552.

*Dasyscaphus parvipennis*, rearing and liberation, P.R. 656.

Dates—

dried, souring, 11.

effect on urinary acidity and blood alkali reserve, 277.

fungus spoilage, relation to structural and chemical factors, 358.

yeasts on, 358.

Day length—*see also* Photoperiodism.

and crop yields, U.S.D.A. 607.

Deer—

browse and acorns as emergency foods, Pa. 652.

footworm of northern Rocky Mountain region, 245.

new nematode from, 384.

Virginia, albinism in, 472.

Deficiency diseases, *see* Diet deficiency and specific diseases.

Dehydration—

methods used in California, 440.

of foods, U.S.D.A. 699.

of foods in wartime, 439, 849.

of fruits and vegetables, 440.

of fruits and vegetables by farmers' co-operatives, U.S.D.A. 404.

of meat on production basis, 439.

of olives, 850.

 washing, effect on hatchability, Mo. 84.  
 weight, effect of boiling, 805.  
 white, *see* Albumin, egg.  
 with olive yolks, acorns as cause of, 519.  
 yolk color and role of pigments in poultry nutrition, Kans. 666.

## Eggplant—

- Phomopsis* blight, breeding for resistance to, R.I. 331.  
 seed stocks, tests, N.Y.State 191.  
 virus-induced "yellows," Tex. 60.

*Egys platycephalus*, control of scale insects by, P.R. 655.

## Eimeria—

- brunetti* n.sp., pathogenic for chickens, 686.  
*nieschulzi* growth-promoting potency of feeding stuffs, nature of, 241.  
 sp., parasite of squirrel, 497.  
*wyomingensis*, new coccidium from cat-tle, 819.

*Elasmopalpus lignosellus*, *see* Cornstalk borer, lesser.

## Electric—

- appliances for saving farm labor, Pa. 688.  
 power on Nebraska farms, Nebr. 105.  
 power serves the dairy farm, Utah 257.

## Electrodes, spectroscopic, cutter for, 6.

## Electron micrographs of protein molecules, 746.

## Elements, minor, absorption and excretion by man, 279.

## Elevator associations, cooperative, percentages of members and directors that were tenants, Tex. 111.

## Elm(s)—

- bark beetle, smaller European, economic importance, 782.  
 bark beetles control, Conn.[New Haven] 499.  
 disease, Dutch, control, Conn.[New Haven] 499.  
 felled, *Ceratostomella ulmi* from insects attracted to, 784.  
 logs treatment against bark beetle, 782.  
 Siberian, in Plains country, effect of Nov. 1940 freeze, 200.

## Elsinoc—

- ampelina*, notes, 357.  
 new species, 25.

## Embryonic development, parallel, in rat and its bearing on superfetation, 470.

## Empoasca—

- fabae*, *see* Potato leafhopper.  
*filamenta*, biology and control, 75.  
 leafhopper on alfalfa, effect of sulfur with other materials, 782.  
 spp., trap-light studies, 75.

## Encephalitis—

- and mosquitoes in Yakima Valley, Washington, 385.  
 eastern and western equine and St. Louis types, 816.  
 St. Louis, *Oulex tarsalis* as vector, 816.  
 St. Louis, virus, relation to equine encephalitis problem, 246.  
 virus of fox, histologic adaptation, 247.  
 western equine, clinical findings in, 242.  
 western equine, in Canada, 385.

## Encephalomyelitis—

- eastern equine, studies, 386.  
 epidemic in man in Saskatchewan, 385.  
 equine—

- brain tissue, phenol as preservative, 100.  
 control, 814.

- induced resistance of central nervous system to experimental infection, 386.

- sources and carriers of virus, 386.

- studies, Kans. 676, U.S.D.A. 97, 676.  
 western, human cases in Manitoba epidemic, 242.

- western, in infants, 242.

- western, isolation of virus from pigs, 822.

## Immunity induced in horses by vaccination, longevity, 683.

## sporadic bovine, Tex. 99.

## sporadic bovine, filtration of causal agent, 101.

## Venezuelan equine and eastern, western, and Argentine virus, cross-immunity studies, 529.

*Endamoeba histolytica*, filth flies as transmitters, 370.

- Endoconidiophora* on London plane tree, control, N.J. 651.
- Endothia parasitica* on chestnut trees in California, behavior, 650.
- Engineering, agricultural—  
in India, 252.  
introduction to, 687.  
suggestions for 1943, Mich. 827.  
work of State experiment stations, 251.
- Enteritis—  
in swine, U.S.D.A. 98.  
infectious, in swine, sulfaquanidine in treatment, 246, 684, 821.  
necrotic, control, U.S.D.A. 665.
- Enterohepatitis, infectious, *see* Blackhead.
- Enterotoxemia of lambs, Tex. 99.
- Entomological nomenclature, status, 499.

- Ergot—  
chemistry, pharmacology, and toxicology, 175.  
germination, 740.  
life history in New Zealand, 175.  
sources for drug purposes, U.S.D.A. 58.
- Eriophyes caryae* on pecan, 783.
- Eriosoma lanigerum*, *see* Apple aphid, woolly.
- Erosion, *see* Soil erosion.
- Ervinia—  
*carotovora*, cause of orchid soft rot, 649.  
*phytophthora*, notes, 63.  
spp. and coliform organisms, relation, 599.
- Erynnia nitida*, biology, 362.
- Erysihe graminis*, protoplasmic continuity in, 642.
- Erythrocyte sedimentation, survey of literature, and measurement, 676.
- Erythroneura*, *see* Grape leafhopper.
- Escherichia*—  
coli, dissimilation of phosphoglyceric acid by, 309.  
n.spp., recognized, 457.  
spp. in factory-packed ice cream, 96.
- Ethanolamine, dietary, effect on liver lipids of rats, 703.
- Ethnobotany, medical, of Navajo Indian, 460.
- Ethylene dichloride—  
emulsion as used for peachtree borer, effect on peach trees, 782.  
toxicity against confused flour beetle, 505.
- Eucalyptus* spp. and their volatile oils in a province of Ecuador, 310.
- Euchlaena*, *Tripsacum*, and corn, genetic and cytological relations, Tex. 42.
- Euphorbia*—  
*lathyris*, proteolytic enzyme in latex of, 29.  
spp., rubber from, N.Dak. 624.
- Eutettia*—  
taxonomic revision of genus, 658.  
*tenellus*, *see* Beet leafhopper.
- Eutrombicula alfreddugesi*, *see* Chigger.
- Ewes—*see also* Sheep.  
Hampshire, mineral mixture to increase lamb production for, N.C. 514.  
native v. western for lamb production, N.C. 514.  
oestral phenomena in, experimental modification, 610.  
oestrus and ovulation in, induction of, Mo. 34.  
onset of oestrus following period of sexual inactivity, nature of, 324.  
plainbodied stud, standard of wool production, 668.  
pregnancy disease, Oreg. 528.  
Rambouillet, fineness of fiber in eight sampling areas, 513.  
range, selection, importance of body weight in, 233, 798.  
range, wintering on grain hay and alfalfa hay, Oreg. 666.  
types of spring lamb production, 797.
- Experiment stations—*see also specific stations*.  
challenge to, by wartime problems, Colo. 867.  
cooperative, in Latin America, 722.  
research on war problems in the home, U.S.D.A. 287.  
use of tests of significance in, 867.

nitrogenous, *see* Nitrogenous fertilizer.

non-acid-forming, Tex. 599.

organic, carbon-nitrogen ratios in, relation to availability of their nitrogen, 597.

placement, N.Y.State 191.

ratios, small whole number, fertilizer triangle for, 455.

substitute, because of war restrictions, Miss. 159.

tests, *see special crops*.

utilization during 1943, Miss. 738.

wartime, for New Jersey, N.J. 168.

## Fescue—

Alta, for pasture and hay, seeding practices and seeds, N.J. 187.

Alta, grazing studies, Mont. 619.

red, burning tops to control "silvertop," Pa. 619.

seed, imported, *Epichloe Typhina* on, 487.

## Fiber(s)—

diameter and wool quality, relation, 421.

identification stain, 422.

imported, replacing with cotton, U.S.D.A. 723.

mixtures, chemical analysis, 420.

new, from casein, 285.

substitute, use of, U.S.D.A. 716.

synthetic, and textiles, Kans. 140.

## Fiber(s)—Continued.

types, as substitutes for jute and manila fibers, 866.

Ficin, anthelmintic activity in dogs, 246.

*Pidia viticida*, *see* Grape rootworm.

## Fig(s)—

canker in Brazil, 493.

Croiste (Cordelia), history, distribution, fruiting behavior, etc., 199.

enzymes of, 728.

souring, yeasts in, 493.

variety tests, Ga.Coastal Plain 331.

## Filbert worm—

parasites, 796.

studies, Oreg. 655.

variability of diapause in, 79.

Films of U. S. Department of Agriculture, catalog and price, U.S.D.A. 699.

Filter-cake compost, 24.

Filth flies as transmitters of *Endamoeba histolytica*, 370.

## Financial—

operations of special improvement districts, Ark. 266.

problems in wartime, U.S.D.A. 835.

## Fir—

crown gall, 359.

## Douglas—

cork, decay in, 780.

cultural identification of fungi causing decay in, 780.

minor weevil pest, 791.

plantations, vital statistics for, 639.

round coast timbers, sapwood depth and absorption limits, 254.

seed from young trees, 200.

Fire ant, vector of *Shigella flexner* V infections, 671.

Fire insurance companies, farmers' mutual, size and efficiency, U.S.D.A. 268.

Fire-retardant chemicals, corrosion studies with, 255.

## Firebrat—

insecticidal action of pyrrolines and pyrrolidines on, 365.

toxicity of ethide to, 782.

Fireproofing standards for pressure-treated lumber, 255.

Fires, forest, *see* Forest fires.

*Fischoederius elongatus* in a calf, experimental infestation with, 245.

## Fish—

and meat meals, protein quality, Mass. 798.

meal for growing and fattening pigs, Ohio 87.

meal, nutritive value, 231.

oil, vitamins A and D potency, 706.

Fisher, gestation period in and protection in California, 652.

Fishery products, home canning, 849.

## Flax—

and related bast fibers, microscopic structure, 670.

as winter crop for south Texas, Tex. 42.

breeding, Kans. 618, Mont. 618.

**Flax—Continued.**

- culture tests, Mont. 619, Tex. 42.
- diseases, 487.
- diseases, seed-borne, evaluation of seed disinfectants for, 350.
- procambium development in, morphological and cytological study, 747.
- rust in Western Australia, 209.
- rust resistance, breeding for, 488.
- rust-resistant varieties, N.Dak. 329.
- stem break and browning in New Zealand, 209.
- variety tests, Kans. 618, Mont. 618, Nebr. 41, Tex. 42.
- wilt or fusariosis in Argentina, 488.
- worm studies, Oreg. 655.

**Flea beetle(s)—**

- injury to tomato transplants, reduction of, 782.
- on cigar-wrapper tobacco, control, 504.
- pale-striped, studies, Ga. 654.
- studies, Tex. 73.

**Fleas—**

- of dogs and cats, U.S.D.A. 98.
- of North America, classification, identification, and geographic distribution, U.S.D.A. 663.
- poultry, sulfur for control, Fla. 250.

**Flies—**

- around unsprayed cows, daily and seasonal behavior of, 783.
- biting, transmission experiments of *Anaplasma marginale* by, 217.
- common to Europe and North America, classification, 662.
- house, *see* Housefly(ies)
- in country and town, control, 654.

**Flood—**

- control study made in mountains, N.C. 446.
- water conservation for range improvement, Mont. 688.

**Floor coverings, felt-base, maintaining in home kitchens, 718.****Flora(s)—*see also* (Plant(s) and Vegetation. of Colorado, mycorrhizas associated with, 741.**

- of the world, geographical guide, U.S.D.A. 169.

State, of United States, 741.

**Florida Station notes, 868.****Flour—*see also* Bread.**

- baking characteristics, Nebr. 5.
- beetle, black, in insect nests, 73.
- beetle, confused—
  - in insect nests, 73.
  - on rice, U.S.D.A. 73.
  - toxicity of certain chemicals as fumigants, 505.
- beetle, red—
  - mineral oils and tar oils for, 217.
  - on milled rice, U.S.D.A. 73.
- enrichment or fortification, background of, 128.
- enrichment, problems in, 151, 152.

**Flour—Continued.**

- moth, confused, in rolled oats packaged in cardboard cartons, cause of infestation, 782.
- peanut, southern bread enriched with, 699.
- quality, chemical factors affecting, Kans. 579.
- starch and amylase in, Nebr. 5.
- wheat, quantity and quality, tempering factors affecting, Kans. 579.
- white, milled by stone milling process, thiamin in, 857.
- white, thiamin in, 436.

**Flower(s)—*see also* Plant(s), flowering, and Plant(s), ornamental.**

- culture in cloth houses, Ohio 331.
- cut, solutions for prolonging life, Ohio 331.
- excessive fertilizer applications, effect, Ohio 331.
- greenhouse, gravel and cinder culture, Ohio 331.
- rooting in sterile culture, 20.
- thrips studies, Tex. 73.

**Fluorescent substance, new, urinary excretion of, effect of pyridoxin, 280.****Fluoride, effect on rat caries and on composition of teeth, 568.****Fluorides, removal from public water supplies, 532.****Fluorine—**

- acquired by mature dog's teeth, 569.
- compounds useful in insect control, Tenn. 785.
- in dicalcium phosphate, toxicity, 704.
- problem in livestock feeding, 514.
- topically applied, effect in dental caries of children, 567.

**Follicle and corpus luteum, method of growth in mouse ovary, 753.*****Fomes annosus* on red cedar, effect of light, 779.****Food(s)—*see also* Diet(s).**

- Administration, British, U.S.D.A. 123, 130.
- analyses, Me. 545.
- and beverage analyses, 406

diseases, Tex. 60.

drying, Tex. 106.

mosaic, U.S.D.A. 58.

**Garments**, serviceability, effect of differences in cotton fibers and harvesting methods, Tex. 140.

**Gases**, respiratory, movement through waxy coatings, studies, 607.

**Gastralgia** in a horse due to bot infestation, 823.

**Geese**—

of North America, life history, 653.

**Geese**—Continued.

rearing on grass alone and with supplementary feeding, 237.

**Genes**, in similar areas of chromosomes, morphological effects, 182.

**Geography**, physical elements of, 443.

**Georgia**—

Coastal Plain Station notes, 288, 575.

Coastal Plain Station report, 426.

Station notes, 143, 868.

Station report, 719.

University notes, 288.

**Geraniol**, pure, preparation, 657.

**Ginger culture**, P.R. 628.

**Glaciers** and perennial snow, 736.

**Gladiolus**—

bulb rots, *Papulaspora* spp. associated with, 70.

thrips control, substitutes for tartar emetic and brown sugar in, 782.

thrips on carnations in greenhouses, control, Wash. 503.

triploid, chromosome number in progeny of, 749.

**Glanders**, U.S.D.A. 97.

*Horosporium olivarium*, cause of olive disease, 493.

Gluconic acid production, repeated recovery and re-use of *Aspergillus niger* in, 726.

Glucose v. triacetin as nutrient in feeds, 797.

Glutathione, synthesis of aspartic acid analog, 582.

Glycerol, synthetic and natural, bacteriological comparison, 176.

Glyoxalase, coenzymes for, 584.

*Glyptometopa* and related genera, new genera erected and new species, 664.

**Gnat**, Clear Lake—

emergence habits, 226.

overwintering larvae, effect of larvicides on, 498.

**Goat(s)**—

and sheep, crosses between, cytological studies, Tex. 35.

Angora, inheritance of type in, Tex. 35.

Angora, v. lamb wethers, fattening in dry lot, Tex. 85.

blind halves in udder, 94.

breeding, management, and judging, 230.

dairy, disease, Oreg. 676.

dairy, improved, care and management, 521.

dairying as use for low-grade land, U.S.D.A. 396.

dairying, directions for, 811.

diseases and parasites, U.S.D.A. 98.

experimental test and mammary development and lactation, 470.

for clearing pastures, Okla. 797.

growth, milk production, and energy metabolism, Mo. 92.

kids, newborn, thyroid enlargement in, 683.

lactating, basal energy metabolism, Mo. 92.

## Goat(s)—Continued.

- lactating, effect of stilboestrol and anterior pituitary extract, 678.
- milk and fat production, effect of thyroxine, Mo. 34.
- milk, bacteriological quality, procedures affecting, 821.
- respiratory quotient in, effect of fasting and refeeding, Mo. 92.
- transference of genes for fineness of fiber from non-Angora to Angora, Tex. 35.

## Golter—

- in newborn pigs, lambs, calves, and colts, prevention with iodized salt, Mont. 678.
- parenchymatous, in newborn goat kids, 683.

Gonadotropic hormones, effects on immature fowl gonads, 614.

Gonadotropin, urinary, effects in prepuberal male rats, 752.

Gonads, increase in weight following injection of male rat pituitary, 751.

*Gonatorrhodiella highti* on diseased American beech in Canada, 650.

*Gontozus indicus*, biology, 793.

Gooseberry diseases, control, N.Y.State 203.

Gourd, luffa or "dishrag," culture, handling, and uses, U.S.D.A. 332.

Governments of Ohio, sources of revenue, Ohio 537.

Grains(s)—*see also* Cereal(s) and Oat(s), Rye, Wheat, etc.

- and corn silage rations, U.S.D.A. 670.

- beetle, flat, on milled rice, U.S.D.A. 73.

- beetle, saw-toothed—

- in insect nests, 73.

- on milled rice, U.S.D.A. 73.

- bin burning, prevention, U.S.D.A. 723.

- bin construction, plywood for, 259.

- borer, lesser, on rice, U.S.D.A. 73.

- containing tarweed seed as poultry feed, 685.

- drying, insect survival in, 784.

- elevators, average margins on grain and supply business, Tex. 111.

- feeding, profitable levels for, Mont. 671.

- germinating, carbohydrate-enzyme relations, Nebr. 41.

- improvement in yield by use of lime, Pa. 595.

- marketing, Kans. 693.

- milling industry in Knoxville trade area, Tenn. 403.

- mites control in British Columbia, 500.

- mites, taxonomy, 665.

- mixture of wheat bran, gluten feed, and soybean meal, digestibility, 232.

- planted at various dates for supplementary pasture, comparisons, R.I. 326.

- production and quality in Knoxville trade area, Tenn. 330.

- requirements of dairy cattle, lowering, Ohio 380.

## Grain(s)—Continued.

## small—

- as good grazing crops, N.C. 473.

- best time for planting, Miss. 325.

- diseases in South Dakota, U.S.D.A. 202.

- diseases in Virginia, U.S.D.A. 640.

- for green manure, Utah 186.

- low yields from poor cultural and fertility practices, N.C. 473.

- plat technic studies, 188.

- seed treatments, Spergon and Thio-san for, U.S.D.A. 58.

- value of applying P to, N.C. 473.

- varieties, Miss. 41.

- variously fertilized, comparative yields, Ga. 617.

- storage, effect on proteins, U.S.D.A. 723.

- stored, insects, Mont. 655.

- stored, protection from insects, 654.

## Gramicidin—

- d-amino acids in, 583.

- effect on bacteria, 457.

- in vitro and in vivo studies, 815.

- value in herd mastitis control program, 91.

(Granary, Russian, North Caucasus as, U.S.D.A. 123.

## Grape(s)—

- anthracnose in Chile, 357.

- Arkansas-grown, composition, Ark. 10.

- berry moth control, Pa. 652, Tex. 73.

- berry moth control, spray supplements for, N.Y.State 785.

- California, maturity studies, 54.

- Champanel, performance under different pruning treatments, 197.

- composition and quality, effects of rootstock, Ark. 53.

- control program in Argentina, U.S.D.A. 696.

- diseases, control, N.Y.State 203.

- diseases in Idaho, Idaho 493.

- juice, samples, ascorbic acid in, 418.

- leaf petioles and blades, potassium in, as indicator of potassium, 482.

- leaf petioles, nitrate in, as indicator of nitrogen status of plant, 482.

- leafhopper feeding injury to leaves, effect on photosynthesis, 503.

- leafhopper feeding on apple leaves, effect on photosynthesis and transpiration, 214.

- mealybug (?) on partridge pea, Ga. 655.

- muscadine, breeding results, 627.

- muscadine, diseases, Ga. 640.

- nutrition, Mo. 47.

- Ohanez, pollen-containing sprays for cross-pollination, 635.

- or vine thrips, economic importance and biology, 75.

- Pierce's disease, 343.

- pollen storage, 482.

- poultry manures for, Okla. 763.

**Grape(s)—Continued.**

pruning and fertilization, N.Y.State 194.  
rootworm, biology and control, Ark. 659.  
rootworm control, Ark. 72.

**varieties—**

and rootstocks, incompatibility between, 481.

identification by seed characters, 196.

new tetraploid, breeding, 467.

resistance to freeze of November 1940, 54.

rootstocks for, N.Y.State 194.

variety tests, Ga.Coastal Plain 331.

**Grapefruit—**

composition and time of maturity, effect of fertilizer practices, 198.

juice, liberal intake, effect, 703.

juices, canned under various processing conditions, ascorbic acid in, 860.

Marsh, yield, quality, and maturity, Ariz. 635.

Grapevines, freeze-injured, methods of handling, Okla. 763.

*Grapholita molesta*, see Fruit moth, oriental.

Grass(es)—see also Grassland, Meadows, Pasture(s), etc.

and legumes grown in association, interrelation, 757.

breeding, Mont. 618, Oreg. 619, Tex. 42.

cultivated, in Alaska, 43.

culture tests, Alaska 617.

**disease(s)—**

host and pathogen indices to, U.S.D.A. 62.

hot-weather, control with chloranil, Pa. 619.

hot-weather, control with Spergon, Pa. 641.

in Wisconsin, U.S.D.A. 640.

endurance on athletic field and airports, R.I. 326.

fertilizer tests, Alaska 617, R.I. 326.

for sheep, nutritive value and digestibility, U.S.D.A. 665.

for winter hardiness, studies, Alaska 617.

growth, improvement by walnut and locust trees, Ohio 326.

insects, Kans. 655.

mixtures, tests, Kans. 618.

n.sp. from North Carolina, 311.

Nebraska, vitamins in, Nebr. 84.

new, grazing tests, Tex. 42.

nutritive value, Ark. 83.

of genus *Echinochloa* of Argentina, 740.

of Mauritius and Rodriguez, 620.

of Nova Scotia, 741.

on South African ranges, carotene in, 232.

pasture, breeding, Ga.Coastal Plain 325, Kans. 618.

pasture, palatability for sheep, Oreg. 666.

pasture, variety tests, Ga.Coastal Plain 825.

prairie, drought resistance of seedlings, 744.

*Pythium* root rot of, 206.

**Grass(es)—Continued.**

reestablishment, measures to promote, S.Dak. 186.

reseeding, stand failures in, due to soil-borne parasites, 203.

response to intensity of clipping, Nebr. 42.

seed drying with device employing infrared radiant energy, Pa. 619.

seed, methods of producing, Nebr. 42.

seed production, Oreg. 619.

sickness in horses, causal agent, 529.

silage, see Silage.

species adapted to South Dakota, S.Dak. 186.

stands, effects of time and method of seeding, Kans. 618.

strains, seed production tests, Pa. 619.

strains, tests, Nebr. 41.

superior varieties or strains grown by station, Oreg. 619.

Transvaal dogtooth, promising for lawns, tests, P.R. 619.

tropical American rusts of, revisionary studies, 642.

turf, ecology, 189.

variety tests, Alaska 617, Kans. 618, Mont. 619, Okla. 755, R.I. 326, Tex. 42.

young, drying for feed, 108.

**Grasshopper(s)—**

control, Mont. 655.

control, dry bait for, 221.

importance of birds in checking, Utah 653.

problem, 217.

studies, Nebr. 73.

Grassland—see also Grass(es), Meadows, and Pasture(s).

farming, relation to soil and water conservation, 107.

farming, relation to water management, 107.

mesas in Badlands of South Dakota, used and unused, 620.

plants, better, for North Carolina, N.C. 473.

research, N.Dak. 620.

**Grazing—see also Range(s).**

crops, variety of, N.C. 473.

excess, harmful aspects, N.Dak. 620.

use, estimating, short-cut method, U.S.D.A. 620.

**Great Plains, new frontiers of, 393.****Green manure—**

crops for soil improvement, Utah 186.

for crops, Tex. 42.

rotation and sequence experiments, Tex. 42.

to replace N fertilizers, value, Ark. 755.

**Greenhouse—**

beds, fumigation to control symphylids, Pa. 628.

crops, nutrient solution culture, Ind. 763.

soil, chloropicrin for sterilizing, Ohio 831.

Grouse, ruffed, eastern, cover requirements in northeast Iowa, 653.

- Growth substance—*see also* Plant growth substances.  
chemical nature, determining, U.S.D.A. 594.
- Guaidine effect on *Nitella*, 606.
- Guanoacetic acid, dietary, effect on liver lipids of rats, 703.
- Guava(s)—  
fresh, canned, and dried, ascorbic acid in, 418.  
production, extending, in California, 636.  
vitamin C in, 714.
- Guayule—  
growing, progress in, Colo. 768.  
root knot nematode resistance, U.S.D.A. 640.  
rubber from, N.Dak. 624.  
rubber, production under irrigation, 637.
- Guinea pig(s)—  
adequacy of simplified diets for, 549.  
coat color, physiological genetics, 469.  
new dietary essentials required by, 705.  
ovary, thecal gland in, 324.
- Guineas subjected to all-night light, sexual activity, 377.
- Gymnosporangium, juniperi-virginianae*, carotenoids of telial galls of, 216.
- Gypsum excess in soils, calcium- and sulfate concentrations in, 24.
- Gypsy moth control, Conn.[New Haven] 499.
- Haemaphysalis leporis-palustris*, *see* Rabbit tick.
- Haemonchus contortus*—*see also* Stomach worms.  
control in sheep, test of anthelmintics for, 682.
- Haemonchus* spp., percentage incidence in cattle, 101.
- Haemoproteus lophortyx* in California valley quail, 251.
- Hair, graying, 570.
- Hair, graying, effect of phenylthiocarbamide ingestion, 412.
- Halatometer, atmospheric, description, 177.
- Halophytes, new perspective in, 601.
- Halticus citri*, *see* Flea hopper, garden.
- Ham(s)—  
commercially cured, palatability and cooking losses, effect of constant oven temperatures, Mo. 127.  
salt absorption and spoilage, relation to curing temperature and pumping, U.S.D.A. 665.
- Hamsters, newborn, infection by mare-abortion virus, 818.
- Hansenula* on dates, 358.
- Hansenula*, taxonomic study, 601.
- Haploidy, problem of, 466.
- Haplospheeria deformans*, notes, 777.
- Haplosporangium parvum* n.sp., isolation from wild rodents and relation to coccidiodomycosis, 524.
- Harlequin bug—  
effect of sulfonated oils combined with cube and derris, 787.  
studies, Tex. 78.
- Harvest work, collaboration by United States and Canada, U.S.D.A. 124.
- Hay—  
crops, ensiled, palatability and fermentation losses, effect of moisture and acidity, 93.  
curling, effect of dew, 758.  
handling methods, 256.  
handling methods and equipment, changes in, 533.  
harvesting methods, newer, Ohio 839.  
harvesting methods, newer, survey, Nev. 538.  
Michigan-grown, as fed to dairy cattle, composition, Mich. 238.  
plants, composition, effect of soils and fertilizers, 20.  
production, trends in, 691.  
storage, trends in methods, 691.
- Haying practices and machinery, Tenn. 287.
- Heat production of cattle, effect of fasting and refeeding, Mo. 92.
- Hegari stored in trench silos for fattening beef cattle, Tex. 85.
- Heifers—  
bred to same sire, artificial v. natural service in, 90.  
growth and development on summer pasture and supplementary concentrates, Ga. 671.  
growth, digestible nutrient requirements, Vt. 520.  
growth rate and milk production, factors affecting, Mo. 92.  
raising, war emergency plans for, 811, Ohio 380.  
supplements to pasture v. no supplements for, Ga. 666.  
weights, oscillatory character of variations in, 808.  
yearling, ability to withstand cold temperatures, 90.
- Heligmodendrium hassalli*, parasite of squirrel, 497.
- Heliothis*—  
*armigera*, *see* Bollworm, Corn earworm, and Tomato fruitworm.  
*virescens*, *see* Tobacco budworm.
- Hellula undalis*, *see* Cabbage webworm.
- Helminth(s)—  
in lungs and alimentary tract of pig in Queensland, 529.  
of poultry in Queensland, 531.  
ova in formalized feces, recovery, method for, 361.
- Helminthosporium*—  
blight of sweet corn, N.J. 490.  
leaf blight of corn, U.S.D.A. 203.  
leaf spot and bacterial wilt on field corn in Indiana, U.S.D.A. 203.  
*sativum* on barley, 486.  
*turcicum*, leaf blight of corn, U.S.D.A. 640.
- Hemicelluloses, feeding value, U.S.D.A. 723.
- Hemispherical scale control, P.R. 656.

- Hemlock, western**—  
cultural identification of fungi causing decay in, 780.  
white floccose aggregate in wood, characteristics and significance, 780.
- Hemoglobin**—  
estimation by alkaline hematin method, 731.  
estimation with undiluted reduced blood, 154.  
formation, amino acids in, 704.  
regeneration in blood donors, rate of, 411.
- Hemoglobinuria**—  
a baffling disease of Midwest, 678.  
in cattle, Kans. 676.  
of calves, in Australia, 528.  
studies, Tex. 99.
- Hemometer, Sicca, construction and standardization, 154.**
- Hemophilus**—  
*gallinarum* infection, R.I. 384.  
*gallinarum*, prevention of spread by sulfathiazole, 686.  
*influenzae suis*, synergistic action on chick embryo, 824.
- Hemorrhagic**—  
degeneration in young rats, dietary factors affecting, 270.  
septicemia, *see* Septicemia.
- Hemp**—  
a war crop for Iowa, Iowa 622.  
effect of day length on, U.S.D.A. 607.  
manila, *see* Abacá.  
production, harvesting, and retting practices, U.S.D.A. 617.
- Hen(s)**—  
annual egg production, N.J. 802.  
broodiness and viability, 88.  
fed yeast-fermented mash as supplement to adequate diet, blood values, 88.  
laying—*see also* Egg production.  
all-mash ration, value of B-Y riboflavin supplement for replacing dried skim milk in, 377.  
comparison of corn, milo, and hegari in diet, 236.  
fat absorption in, 237.  
hegari v. corn for, Tex. 85.  
keeping in batteries, Oreg. 666.  
pastures and vitamins for, Miss. 231.  
pastures for, 377.  
poisoned by calcium oxide, 104.  
rough rice and no mash v. mash feeding, Tex. 85.  
sunlight lamps for, Nebr. 379.  
value of green feeds for, Oreg. 666.  
male copulatory behavior in, following administration of male hormone, 761.  
on normal and low fat rations, absorption and retention of carotene and vitamin A by, 803.  
pantothenic acid requirement, 377.  
premature expulsion of eggs by, 472.  
premature oviposition by, action of vasopressin and oxytocin on, 88.
- Hen(s)—Continued.**  
S-4 lamp radiation for, Nebr. 84.  
vitamin A deficient, ascorbic acid storage in, 803.  
Henequen plantings in Haiti, Cuba, and Mexico, U.S.D.A. 617.  
*Hennous confertus*, biology, 227.  
Herbage, composition and yield, effect of fertilizer treatments, Tex. 42.  
Herbs, tests, Ga. 627.  
Herd analyses, method of presenting, 807.  
Herd mastitis control program, value of gramicidin in, 61.  
Hereditry—  
of plant characters induced by radiation, 608.  
of wavy-leaf character in peach, 318.  
*Hesperotettix* genus in Utah, 221.  
Hessian fly—  
on wheat, Kans. 655.  
studies, Nebr. 73.  
*Heterakis*—  
*gallinae* eggs, studies, 815.  
*gallinae*, parasite of partridges, 498.  
*isolonche* in golden pheasant, 251.  
*Heterodera rostochiensis*—  
cyst population of a field over a series of years, 210.  
notes, U.S.D.A. 202.  
*Heterosporium echinulatum* of carnations in greenhouse, 649.  
*Hevea brasiliensis*, crown budding for disease resistance, U.S.D.A. 341.  
*Hexamita* sp.—  
and infectious sinusitis in turkeys, Oreg. 676.  
from ringed-neck pheasant, 686.  
Hexuronic acids, identification as benzimidazole derivatives, 725.  
*Hibiscus* sp., leaf spot induced by *Phytophthora* *sporangiae*, 649.  
Hickory—  
reproduction in Southeast, pests of, 219.  
spiral borer, notes, 219.  
Hides and skins, domestic, conserving, U.S.D.A. 723.  
Histidine, preparation by 3,4-dichlorobenzene-sulfonic acid, 581.  
Histology, comparative, textbook, 578.  
Hog cholera—  
control, U.S.D.A. 676.  
diagnosis, cell changes in gall bladder as aid in, 245, 814.  
immunity, Nebr. 99.  
tissue vaccine, immunological studies, 814.  
virus isolation from supposedly immune swine, 822.  
virus, neutralization by hog cholera antiserum, 103.  
Hogs, *see* Pig(s) and Swine.  
Holly—  
cut, defoliation in, cause and control, Oreg. 767.  
cuttings, defoliation by *Rhizoctonia*, 359.  
Home economics, experiment station research in, effect of war, 126.

- Homocysteine**—  
 dietary, effect on liver lipids of rats, 703.  
 synthesis and its replacement of cystine in diet, 581.
- Homogenization studies**, 520.
- Honey**—  
 and nectar, pollen grains in, 510.  
 effect on calcium retentions in infants, 133.  
 marketing by retail grocers, Mich. 269.  
 of different localities, vitamin content, 550.  
 wine and honey brandy, 296.
- Hop(s)**—  
 culture and labor schedule, Oreg. 628.  
 diseases in 1941, 775.  
 downy and powdery mildews, spraying for, N.Y.State 203.  
 downy mildew, spreaders for use with fungicides in spraying for, 66.  
 farming in Yakima Valley, Wash. 262.  
 gray mold studies, 775.  
 leafhoppers and sooty mold on, spraying for, N.Y.State 203.  
 varieties, new, test, N.Y.State 332.  
 variety tests, N.Y.State 194.
- Hoplocampa testudinea* on Vancouver Is. land, 500.
- Hoplosyllus affinis*, parasite of squirrel, 497.
- Hopvine borer as hop pest, N.Y.State 218.
- Hordeum**—  
*sativum* embryo growth in culture, 29.  
 wild species, cytology, 33.
- Horistonotus uhleri*, see Wireworm, sand.
- Hormones**—  
 gonadotropic, see Gonadotropic.  
 lactogenic and gonadotropic, effects on hypophysectomized pregnant rats, 184.  
 lactogenic, bird and rabbit response to, Mo. 34.  
 plant, see Plant growth substances.  
 thyrotropic, assay, comparison of guinea and chick thyroid in, Mo. 34.  
 thyrotropic, in rat pituitary, Mo. 34.
- Horufly**—  
 on cattle, acidified nicotine sprays for, 227.  
 studies, U.S.D.A. 98.
- Hornia*, systematics of, 659.
- Horse(s)**—  
 body fluids of, ascorbic acid in, 103.  
 bots and their control, U.S.D.A. 97.  
 breeding hygiene, 814.  
 breeding, management, and judging, 230.  
 diseases and parasites, U.S.D.A. 97.  
 draft, feed requirements and selling price, Mich. 235.  
 effects of phenothiazine, 530.  
 farm, Morgan, work of, U.S.D.A. 800.  
 fistulous withers, use of *Brucella abortus* vaccine in, 246.  
 insect pests, U.S.D.A. 97.  
 nutrition, recent developments in, 800.  
 parasites of and treatment for removal, U.S.D.A. 676.
- Horse(s)**—Continued.  
 pedigrees in, importance, 750.  
 rations for, U.S.D.A. 665.  
 Thoroughbred, stakes winning and poor performing, genetic analysis, 610.  
 wheat as feed for, Utah 667.
- Horsepower**, farm, efficiency, 513.
- Hosiery**—  
 cotton, research, U.S.D.A. 716.  
 silk and Nylon, wearing qualities compared, 866.
- Hotbeds**, electric, effect of methods of heating and covering on field production of vegetables, 763.
- Housefly(ies)**—  
 as transmitter of *Endamoeba histolytica*, 370.  
 central nervous system, effects of pyrethrum and activator on, 81.  
 effect of organic halides on, 370.  
 recovery from effects of toxicants, effect of temperature, 663.  
 relation to transmission of bovine mastitis, 101.  
 source of pollution in food establishments, 662.  
*Tephrosia* extract against, 658.  
 toxicity of  $\alpha$ ,  $\beta$ -dibromo- $\beta$ -nitroethyl benzene to, 782.  
 toxicity of paradichlorobenzene to third-instar larvae, 509.
- Household equipment**—  
 and housing research, U.S.D.A. 719.  
 work, and storage space, 718.
- Houses**, construction, use of preserved wood in, 254.
- Housing**—  
 defense, decay of, U.S.D.A. 640.  
 low-cost, studies, Ark. 261.

flavor scoring, comparative standardization, 814.

frozen cream as source of fat in, Mich. 675.

high serum solids, keeping quality, Mo. 92.

manufacture, saving sugar in, 383.

mix, short-time high-temperature pasteurization, 813.

oxidized flavor in, prevention, 812.

properties, effect of dextrose and sucrose, 382.

properties, effect of forewarming temperatures of condensed skim milk in, 92.

ribbon, new flavors in with fruit purées, 522.

ripple sirups, meeting sugar shortages in preparing, 675.

sandy, lactose crystals in, petrographic microscope for study, Mo. 5.

shrinkage, research on, 520.

stabilizers, role of, and needs for war purposes, 241.

sugars in, 240.

sweetening agents for use in, 520, 814.

sweetness of, U.S.D.A. 671.

technical literature, 240.

texture, structure, and stability in, 92.

Illinois Station notes, 575.

Illinois University notes, 575.

Immigrant, European, in rural Rhode Island, R.I. 405.

Income, relation to farm capital, 393.

1,3-Indandiones, insecticidal properties, effect of acyl groups, 500.

Index numbers of production, prices, and income, Ohio 110, 394, 537.

Indexes of United States and Oklahoma prices, Okla. 261.

Indian-meal moth—

in insect nests, 73.

on milled rice, U.S.D.A. 73.

Indiana Station notes, 427, 575.

Indianwheat, mucklage from, 570.

Infant(s)—see also Children.

effect of honey on calcium retention, 133.

feeding, textbook for students and practitioners of medicine, 410.

newborn, healthy, hematologic standards for, 278.

nutrition, textbook, 410.

premature, ascorbic acid requirement, effect of diet, 560.

Infiltrometer, automatic self-recording, 303.

Influenza—

equine, pathology, 823.

virus group, affinity of Newcastle disease virus to, 242.

Inositol synthesis in mice, 703.

Insect(s)—see also Entomology.

and other arthropods in buildings in British Columbia, 500.

and pests in stored products, 500.

apparatus for obtaining interval collections, 498.

attractants and repellents for, 219.

attracted to felled elm trees, isolation of *Ceratostomella ulmi* from, 784.

blood, pH of, and bearing on in vitro cytological technic, 656.

control and pest survey, Okla. 783.

control by aircraft, 657.

control, fluorine compounds for, Tenn. 785.

control in Hawaii, 218.

control in home vegetable garden, N.J. 784.

damage, forest, use of frass in identification, 502.

eastern oceanic, distribution and origin, 362.

eggs, penetration of oils into, N.H. 220.

entomophagous, measurement of effect on population densities of hosts, 783.

food caches as reservoirs and sources of stored products pests, 73.

forest, see Forest.

hosts of *Beauveria bassiana* on elm in United States, 650.

household and storage grain, effect of high temperature, 783.

immature, killing and preserving fluid for, 499.

in Canada, biological control, 657.

industrial fumigation against, U.S.D.A. 221.

infesting dried fruits, control, 784.

injurious, biological control, N.Y.State 218.

injurious to crops, see special crops.

integument of, relation to entry of contact insecticides, 363.

**Insect(s)—Continued.**

- western, fattening, value of various rations for, Ind. 799.
- western, feeding, 234.
- wheat bran, corn, and soybeans for, Pa. 666.

## Land(s)—see also Farm land(s).

- abandoned cultivated, returning to grazing, Colo. 756.
- acquisition program under Title III of Bankhead-Jones Farm Tenant Act, U.S.D.A. 266.
- classification, Mo. 15.
- classification and valuation for assessment purposes, Mont. 399.
- conditions in Charlton Co., Mo., U.S.D.A. 737.
- credit, see Agricultural credit.
- Federal, conservation expenditures on, 393.
- for recreational use, zoning, 125.
- government purchase, social effects due to construction of Sardis Dam and Reservoir, Miss. 537.

## Land(s)—Continued.

- hard, areas, range studies in, Nebr. 42.
- irrigated farm, system of economic classification, Utah 595.
- ownership and operating tenure in Imperial Valley, Calif. U.S.D.A. 840.
- rented, landlord supervision of operation, Tex. 111.
- settlement of Russian-Germans in the Dakota Territory, 843.
- tenure and related problems, Kans. 693.
- tenure in Yazoo-Mississippi Delta, Miss. 537.
- tenure policies at home and abroad, 265.
- uncultivated, in western United States, use, 536.
- use and related changes in Knott Co., trends in, Ky. 537.
- use and rural living on urban margin, R.I. 405.
- use areas, estimating from aerial photograph index sheets, 202.
- use experience in Callaway Co., Mo. 112.
- use in Schuyler Co., economic study, [N.Y.] Cornell 262.
- use in towns in Arrostook Co. Me. 398.
- use, recreational, economic aspects, Mo. 113.
- use relation to sedimentation in reservoirs in Trinity River Basin, Tex. 106.
- use, rural, outstanding Federal and State laws affecting, U.S.D.A. 840.
- values, U.S.D.A. 270.
- values and transfers in North Dakota, N.Dak. 394.
- values, keeping track of, through periodic surveys, U.S.D.A. 835.
- Landlord-tenant relation, legal aspects, Ohio 394.
- Langstroth, life of, 795.
- Lanthionine—
  - formation on treatment of insulin with dilute alkali, 581.
  - dl, isolation from various alkali-treated proteins, 725.
- Laphygma frugiperda*, see Armyworm, fall.
- Larch—
  - mycorrhizal relations, 176.
  - shoot moth, biology and natural control, 659.
- Lard, melting point, effect of wheat and corn in, Oreg. 666.
- Larkspurs, annual, viroses of, Calif. 779.
- Laryngotracheitis—
  - and pox, failures in immunization against, cause, 814.
  - infectious, diagnosis and control, 100.
  - infectious, in chickens, Oreg. 676.
- Latrodectus indistinctus*, insect food and hymenopterous parasites of, 512.
- Laundrying tasks, home, relation to worker and equipment, 718.
- Laundry processes, home and commercial, efficiencies, 425.
- Lawngrass, Japanese, *Claviceps yanagawaensis* in imported seed of, 62.

**Lead arsenate—**

basic, stability with spray ingredients, 782.

substitutes for, Mo. 47.

Lead-cable borer, attack on asphalt roofing material, 72.

Lead determinations with dithizone, factors affecting, 6.

**Leaf(ves)—**

carotene, determination, method, 8.

crumpler, studies, Tex. 73.

green, chlorophyll-protein compound, 172.

stomatal movements, theory of porometers used in study, 30.

Leafhoppers—*see also special hosts.*

control, Tex. 73.

feeding injury to leaves, effect on photosynthesis, 503.

of genus *Empoasca*, trap-light studies, 75.

redbud, studies, Kans. 655.

six-spotted, protecting plants against, 222.

Lease renewal, automatic, Iowa statutory provisions for, 394.

Legume(s)—*see also* Green manure and Alfalfa, Clover, etc.

and grasses grown in association, interrelation, 757.

boron fertilization, 758.

breeding, Oreg. 619.

bugs in seed alfalfa, insecticidal control, 365.

cost of seeding and yields, Mo. 110.

crops, variation of lime requirements, Pa. 595.

culture tests, Alaska 617.

diseases, U.S.D.A. 58.

effect on soils and crops, Miss. 597.

fertilizer tests, Alaska 617, Miss. 186, 326.

for winter hardiness, studies, Alaska 617.

hays, value in rations of fall farrowed pigs, 513.

in Alaska, 43.

inoculant inspection, N.Y.State 159.

inoculant tests, N.Y.State 762.

interplanted with oats for hay, Tex. 42.

nitrogen fixation in soils by, Mo. 15.

nodules, excised, N fixation experiments, 461.

nutritive value, Ark. 83.

palatability for sheep, Oreg. 606.

roots, excretions of nitrogen compounds from, 457.

roots, loss of nodules from, significance, 621.

seed production tests, Pa. 619.

silage, ground corn as preservative, Ohio 380.

v. corn for fattening calves, Mich. 233.

value for maintaining soil fertility, Miss. 300.

variety tests, Alaska 617, Kans. 618, Tex. 42.

**Legume(s)—Continued.****winter—**

culture tests, Tex. 42.

fertilization, early seeding, and drainage important, Miss. 325.

fertilizer tests, Tex. 42.

for green manure in Cotton Belt, U.S.D.A. 43.

for soil improvement, Ark. 40.

growth, effect of acid-forming fertilizer not supplemented with limestone, 185.

increasing to meet nitrogen shortage, Miss. 41.

inoculation for, Miss. 325.

varieties and kinds, Miss. 41.

woody desert, behavior at wilting percentage of soil, 30.

**Lemon grass—**

distillation residues, analyses, P.R. 579.

essential oils from, studies, P.R. 579.

Lemon juice, effect on calcium retention, 277.

Leoti, a sorghum for starch, Nebr. 475.

Lepidoptera of Mexico, systematic and zoogeographic catalog, 508.

**Lepidopterous—**

larvae, host plants and parasites, 661.

pests of corn in Trinidad, 661.

pests on fruit trees and their parasites in Ireland, 661.

*Lepidosaphes beekii*, *see* Purple scale.

*Leptinotarsa deccimicincta*, *see* Potato beetle, Colorado.

*Leptosphaeria* spp., new and interesting from Mt. Shasta, 601.

Leptospirosis among dogs in Honolulu, 530.

**Lespedeza—**

annual, for Florida pastures, Fla. 329.

as crop to precede grasses on poor land, N.C. 473.

biological value for dairy helpers, 90.

diseases, Ga. 640.

fertilizer tests, Miss. 186.

in Coastal Plain area, 761.

increased yields by lime and phosphate, N.C. 446.

Korean, seed, as protein supplement for milk production, Mo. 380.

Korean, seed, feeding for milk production, 90.

nutrients in, effect of soil fertility, Ind. 737.

photoperiod effects on, Mo. 25.

protein and mineral content, Ga. 579.

variety tests, Miss. 186.

*Lespedeza sericea*, *see* Sericea.

**Lettuce—**

cos or romaine, response to chloropicrin soil treatment, phosphate, and lime, 808.

cultural tests, Ga.Coastal Plain 331.

damping-off control, N.C. 485.

disease symptoms caused by bean leafhopper, 646.

fertilizer tests, Ga.Coastal Plain 331.

## Lettuce—Continued.

growth and yield, effects of partial defoliation at transplanting time, U.S.D.A. 47.

head, culture, P.R. 629.

head, Great Lakes, new variety adapted to summer conditions, Mich. 764.

iceberg, spacing and fertilizer studies, 192.

interspecific genetic relations in, 749.

nutrient absorption by, in Salinas Valley, California, 764.

on Everglades muck, effect of starter solutions, 191.

production in Mississippi, Miss. 332.

quality, production under Mississippi conditions, Miss. 49.

seed treatment, Miss. 354.

seed, viability, [N.Y.] Cornell 192.

tests, Ga. 627.

value of molybdenum for, 48.

varieties, breeding, U.S.D.A. 627.

varieties for greenhouse culture, development, Ohio 331.

## Leucosis—

avian, complex, U.S.D.A. 676.

avian, complex, serological studies on, 825.

avian, complex, vinylite-resin corrosion preparations in study, 104.

avian, in embryos, interspecies transmission, 104.

fowl, production of specific antibodies against the agent, 686.

fowl, studies, Mo. 99.

## Leukemia—

in animals, spontaneous and experimental, 523.

lymphogenous, Kans. 676.

transmissible chicken, test of greenmilk for, 825.

## Leukopenia in rats, prevention and treatment, 526.

## Lice—

and other parasites of domestic animals, 502.

head and body, new methods of control, 654.

of pigs, U.S.D.A. 98.

on native American rodents, host distribution, 865.

poultry, sulfur for control, Fla. 250.

*Ligustrum vulgare*, olives grafted on, behavior, 316.

## Liliaceae, virus disease in Portugal, 495.

## Lily (ies)—

bulb rot diseases, 495.

culture, suggestions for beginner, 637.

Easter, growth and flowering, effect of bulb treatments, Mich. 637.

insect pests, 656.

Lima beans, *see* Beans, lima.

## Lime—

and phosphorus as primary soil needs, Pa. 595.

downward movement in soils, N.C. 446.

## Lime—Continued.

importance in feedlot ration, in sanitation, and in treatment of manure, Colo. 867.

products, inspection, Mass. 739.

## Limestone—

dolomitic, effect on soils and crops when used in complete fertilizers, 454.

finely ground, for agricultural use, Mo. 15.

## Liming—

experiments, 598.

relation to efficiency of fertilizers, 454. the land, N.J. 168.

various soils and crops, effect, Miss. 597.

## Limoniis—

*agonus*, *see* Wireworm, eastern field.

*californicus*, *see* Wireworm, sugar beet.

*canus*, *see* Wireworm, Pacific coast.

## Linen in part linen fabrics, quantitative analysis, 803.

## Linkage relationships of mendelian factors in beets, 34.

## Linseed meal, old-process v. solvent-process, as supplement for fattening calves, Nebr. 84.

## Lipase—

activity from  $-70^{\circ}$  to  $50^{\circ}$  C., kinetics as function of temperature of, 239.

in milk, role in development of rancidity, 239.

## Listerellosis in a goat, 390.

## Listeria infection, histopathological changes in ophthalmic response of animals to, 678.

*Listroderes obliquus*, *see* Vegetable weevil.

## Litmus, standardization, progress in, 607.

## Live oak mildew disease control, 359.

## Liver—

abscesses in feed lot cattle, U.S.D.A. 676.

chemical analyses, relation to its vitamin A potency, 731.

concentrate as source of unrecognized vitamins required by chicks, 379.

fat of rats, effect of dietary factors, 703.

flake in cattle, sheep, and goats, Oreg. 676.

Livestock—*see also* Animal(s), Mammals, Cattle, Sheep, *etc.*

and forestry enterprises on farms in Ozark region, Ark. 115.

and livestock products, marketing, Kans. 693.

artificial insemination of, Minn. 184.

breeding and insemination, Ga. 611.

closed herds, effect of progeny testing on progress from selection within, 610.

diseases, *see* Animal disease(s) and *specific to kinds*.

feeding and management, problems in, Miss. 230.

feeding, fluorine problem in, 514.

feeding, use of wheat for, Wyo. 373.

general science of, 372.

## Livestock—Continued.

- grazing on wild land and cut-over land, Mich. 667.  
 industry in Southeast, appraisal, Ala. 114.  
 industry, relation to native vegetation, Tex. 25.  
 keeping healthy, U.S.D.A. 97.  
 management, 272, 372, Kans. 618.  
 market classes and grades, U.S.D.A. 403.  
 marketing practices, S.Dak. 208.  
 movement at Kentucky auction markets, Ky. 539.  
 nutrition problems, physiological approach, 231.  
 parasites and insects affecting, U.S.D.A. 97.  
 physiological and genetic studies by Bureau of Animal Industry, U.S.D.A. 611.  
 poisoning, *see* Plants, poisonous, and specific plants.  
 production—  
   experiments, Ohio 373.  
   treatise, 230.  
   wartime, improving range conditions for, U.S.D.A. 620.  
 raising in U. S. 1607-1860, history, U.S.D.A. 839.  
 rations, computing, direct methods, 231.  
 relation between body weight, amount of wool or feathers, and temperature, Mo. 84.  
 seasonal rhythms in, Mo. 34.  
 statistics, *see* Agricultural statistics.  
 transportation and processing problems, U.S.D.A. 694.  
 vitamin A and carotene requirements, 798.  
 vitamins for, Mo. 514.  
 Living, standard of, *see* Standard.  
 Lizard(s)—  
   brown-shouldered, seasonal insect food of, 783.  
   range, as insect predators, 362.  
*Lobelia cardinalis* seed, microsporogenesis and development, 465.  
 Loco weed poisoning, Tex. 99.  
 Locust(s) (insect)—  
   brown, incipient outbreaks, forecasts, 658.  
   grouse, genetics, 612.  
   grouse, inheritance of, Kans. 655.  
   in South Africa, acarine parasites infesting, 658.  
 Locust (tree), honey, *Thyronectria austro-america* disease of, U.S.D.A. 58.  
 Loess deposits, variations in properties and distribution, Ill. 16.  
 Log and stumpage prices for 1939 and 1940, U.S.D.A. 58.  
 Loganberry dwarf disease, Oreg. 641.  
*Lonchocarpus nicou*, culture and physiology of, P.R. 629.  
*Lophodermium* spp., new and interesting from Mt. Shasta, 601.  
 Louisiana Station notes, 868.  
*Lowostoge sticticalis*, *see* Webworm, beet.

## Lucilia—

- pallescens* as transmitter of *Endamoeba histolytica*, 370.  
 spp., seasonal distribution, 81.  
 Lumber—*see also* Timber and Wood.  
   hardwood, supplies, Ark. 768.  
   pressure-treated, fireproofing standards for, 255.  
   requirements on farm, U.S.D.A. 830.  
 Lung lobation in mice, factors affecting, 30.  
 Lungworms—  
   in sheep and goat, phenothiazine for control, 821.  
   of domestic and bighorn sheep in Wyoming, Wyo. 245.  
   studies, Oreg. 670.  
 Lupine diseases, Ga. 640.  
*Lupinus albus* growth, effect of sulfanilamide and derivatives, 606.  
 Lygus—  
   bugs in seed alfalfa, insecticidal tests for, 787.  
   *hesperus* studies, Tex. 73.  
   injury to alfalfa plants, 362.  
   on cotton, control by dusts, 504.  
   *pratensis oblongatus*, *see* Tarnished plant bug.  
   spp. on potatoes, Nebr. 73.  
 Lymph nodes in male rats, effect of thyroidectomy, castration, and replacement therapy, 755.  
 Lymphomatosis-osteopetrosis in chickens, serial passage of, 104.  
 Lymphomatosis studies, Kans. 676.  
 Lysimeter studies, 18.  
 Macadamia seeds, chemical constituents, relation to chlorosis in seedlings, 630.  
 Machinery, *see* Agricultural machinery.  
 Mackerel—  
   bacterial flora, effect of fast-freezing, 840.  
   oil, vitamins A and D potency, 706.  
*Macronoctua onusta*, *see* Iris borer.  
 Macrosiphum—  
   *pisi*, *see* Pea aphid.  
   *sonchi* on orange-glowvine, P.R. 656.  
*Macrosteles divinus*, *see* Leafhopper, six-spotted.  
 Magnesium—  
   arsenate, determination in treated wood, 154.  
   available, determination, laboratory method, R.I. 301.  
 Maine Station notes, 575.  
 Malaria—*see also* Mosquito(es) and Anophelids.  
   avian, and chemotherapy, 248.  
   avian, parasites, preservation by low-temperature freezing, 248.  
   in man, microscopical diagnosis, manual, 662.  
 Malnutrition, prevalence of, 565.  
 Malt tonic, vitamin B complex in, 856.  
 Mammals, breeding season in, after transference to new latitude, 38.

**Mammary—**

and teat development, experimental, in goat, 470.

development, mammogen control of, 90.

**gland—**

fat metabolism of, effect of ketosis, 672.

growth in hypophysectomized castrated guinea pigs, 754.

of ovariectomized rats, effect of progesterone, 753.

oxygen uptake and CO<sub>2</sub> elimination, 91.

structure in rat, relation to thyroid, 616.

tissue, bovine, lipolytic activity, 807.

tissue, enzymatic hydrolysis of diacetin by, 91.

growth in male mice fed desiccated thyroid, 321.

involution in mice, 324.

**lobule-alveolar growth—**

effect of thyroxine, 471.

stimulation by progesterone-like activity of steroid compounds and of diethylstilboestrol, 471.

stimulation, effect of thyroxine, 91.

system, effect of selection of nipples by suckling rats, 471.

**Man (men)—**

and animals, bacterial infections and parasites common to, U.S.D.A. 97.

healthy, hematologic values for, 548.

swine erysipelas infection in, Nebr. 242.

**Manganese—**

absorption and excretion by man, 279.

active, in soil, determination, 452.

content of commercial matches, Mass. 798.

deficiency in rat, 278.

deficiency, lime-induced, production on eroded Kentucky soil, 598.

effect on calcification in rat, 277.

for oats and white beans in Michigan, 168.

**Mango—**

of dogs, U.S.D.A., 98.

of equines, U.S.D.A., 97.

of swine, U.S.D.A. 98.

**Mangels—**

fertilizer tests, R.I. 326.

vitamin B deficiency in, R.I. 326.

**Mango, polyembryony in, P.R. 629.****Mangosteen cultivation, 25.****Manila—**

fibers, substitutes for, 866.

hemp, *see* Abacá.

**Manure—**

artificial, preparation and use, Mass. 165.

conserving fertilizer value, effect of amendments in, Vt. 447.

**Maple(s)—**

bleeding canker, response to chemotherapy and fertilization, R.I. 344.

Japanese, identification, 601.

products research, N.Y.State 149.

**Maple(s)—Continued.**

trees, sugar, effect of location and character on sugar in sap of, 638.

trees, vegetative propagation and sex, 342.

**Mare(s)—**

natural breeding and artificial insemination, Miss. 230.

oestrous cycle conditions, relation to oestrin of follicular fluid in urine, Mo. 34.

oestrus and ovulation in, 615, Mo. 34.

ovulation in, induction of, Mo. 34.

*Marietta* spp., effect of dormant sprays on, 510.

Market, French, in New Orleans, operating practices on farmers' section, La. 122.

Market gardens, *see* Truck crop(s).

Market reports, U.S.D.A. 124, 540.

Marketing—*see also* special products.

of farm products, wartime, U.S.D.A. 841.

problems, wartime, Ark. 841.

Marten, fur quality and greater prolificacy,

effects of feeding, Alaska 652.

Massachusetts College notes, 568.

Massachusetts Station notes, 288, 568.

**Mastitis—**

and herd practices at Michigan State College, 91.

and the udder, 682.

as important dairymen's problem, N.C. 520.

control, lactovaccine in, 91.

germs, shedding by apparently normal cows, Ohio 383.

in cattle, virus as cause, attempt to demonstrate, 527.

**streptococcal—**

control by segregation program, [Conn.] Storrs 819.

effect of injections of Novoxil in udder, 820.

tyrothricin in treatment, results, 102, 682.

value of udder infusion in treatment, 820.

studies, Kans. 676, Tex. 99, U.S.D.A. 97, 676.

sulfanilamide administered directly into mammary gland for, 101.

sulfanilamide in iodized mineral oil for, preparation, 819.

treatment, role of gramicidin in, 244.

treatment with homogenized oil-sulfanilamide, 244, 681.

Mathematics in agriculture, 272.

*Matuococcus bisetosus* on ponderosa and Jeffrey pines, seasonal history, 224.

May beetles, wingless, Tex. 73.

Maydeae tribe, proposed taxonomic change in, 741.

Meadows—*see also* Hay, Grass(es), Grassland, and Pasture(s).

improvement, Nebr. 41.

mountain, proper use, U.S.D.A. 327.

**Mealybug—**

apple, and its allies in northeastern America, 223.

apple, control by dormant sprays, 223.

coconut, parasite of, P.R. 655.

problem and orchard mites, 230.

sugarcane, experiments with, 658.

**Measures and weights in United States, inspection and control, U.S.D.A. 401.**

**Meat—see also Beef, Lamb, Pork, etc.**

and human health, 281.

and milk hygiene, report of committee on, 814.

animals, wartime marketing problems of, Ark. 841.

canned, processing, Tex. 127.

canning methods, Calif. 409.

cooking problems, contributions of applied research to, 272.

dehydration on production basis, 439.

freezing preservation, N.Y.State 272.

home canning, U.S.D.A. 129.

in nutrition, 273.

meal and soybean meal mixture, gross values, 236.

meal, nutritive value, 231.

microbiology, 846.

nicotinic acid in, 858.

pantothenic acid in, effect of enzymatic digestion on, 153.

phenols in, estimation, 589.

plants, small, developing dehydrating method for, 440.

preparation of muscular tissues for histological study, 514.

preservation studies, U.S.D.A. 700.

products in feeding program, 374.

smoked, studies, 516.

supply program of 1943, Mich. 707.

tendering during cooking, factors responsible for, Tex. 127.

problem in North Dakota, 781.

rice field, breeding habits, 370.

rice field, control, Ark. 783.

spray-killing, improvements made to equipment for, 662.

studies in military establishments, 370.

Mothproofing tests, 656.

Motors, fractional horsepower, protection for, Mich. 600.

Mounting media, notes, 607.

*Mucor ramannianus*, interaction with thiamin, 602.**Mucorales—**

nuclear behavior in, 310, 486.

spore dispersal in, 310.

Mucosa of pigs, lipids of, during absorption of fat, 234.

Mulberry family, rubber from, N.Dak. 624.

Mulch materials, production in orchard, Ohio 331.

**Mules—**

breeding, management, and judging, 230.

diseases and parasites, U.S.D.A. 97.

insect pests, U.S.D.A. 97.

*Musca domestica*, see Housefly(ies).*Muscardi comosum*, virus disease affecting, 495.

Muscular dystrophy, nutritional, cure in rabbit, 716.

**Mushroom(s)—**

casing soil, control of fungi in, 355.

culture, composting of manure for, Pa. 628.

fly control, mixed thiocyanate and pyrethrum dusts for, Pa. 652.

food value, 846.

**Muskmelon(s)—**

aphid abundance, relation to cotton, Okla. 783.

breeding, N.Y.State 191.

breeding for the South, 627.

downy mildew, spraying and dusting for, Tex. 60.

fruiting behavior, effect of number of plants per hill and hill spacing, 627.

growing and handling, Calif. 49.

increasing fruit set in, pruning as aid, 764.

leaf spot, effects of sand and nutrient supply, 775.

**powdery mildew—**effect of vitamin B<sub>1</sub> on, 355.

genes for resistance in, 646.

reaction of strains to, 354.

production, trends and prices by areas, U.S.D.A. 399.

seed production, P.R. 629.

- Muskmelon(s)**—Continued.  
 spoilage, analysis of market inspection reports, U.S.D.A. 211.  
 variety tests, Ga.Coastal Plain 331.  
 vitamin C in, Ohio 409.
- Muskrat(s)**—  
 fluctuations in numbers, 380.  
 larval cestodes from, 248.  
 of Louisiana, parasitological survey, 380.
- Mustard**—  
 black, metabolism, effect of sulfur deficiency, 773.  
 greens, dehydration tests, 849.  
 plants, black, volatile sulfur in, 462.  
 tests, Mont. 619.
- Mutations, X-ray-induced visible gene in**  
*Drosophila*, analysis of data, 36.
- Mutton production, increasing after the war,**  
 796.
- Mycogone perniciosa* in mushroom soil, control**  
 with chloropicrin, 355.
- Mycorhiza(s)**—  
 associated with Colorado flora, 741.  
 formation in nature, 176.
- Myriangiales, new discoveries in the Americas,**  
 25.
- Naphthalene**—  
 aerosol, stabilization, 220.  
 conversion to salicylic acid by bacterial oxidation, Pa. 583.
- Napier grass**—  
 composition and grazing value under controlled management, 622.  
 grazing tests, 797.  
 potash deficiency symptoms in, 350, 622.
- Narcissus**—  
 basal rot increased by use of synthetic hormones and bases, 495.  
 bulb fly, biology in Northwest, U.S.D.A. 509.  
 bulbs, tolerance to hot water-formalin treatment, variations in, 74.  
 lepidopterous pest of, biology, 654.  
 mosaic virus, insect transmission of, 495.
- Narcissus tazetta*, virus disease affecting,**  
 495.
- Naval stores**—  
 making, handling, and storing, wartime changes in, U.S.D.A. 723.  
 military uses for, U.S.D.A. 723.  
 studies, U.S.D.A. 723.
- Nebraska Station notes,**  
 575.
- Nebraska Station report,**  
 142.
- Nebraska University notes,**  
 575.
- Neighborhoods, natural, white and Negro,**  
 representation in administrative agencies,  
 Tenn. 124.
- Nemacides, tests of chemicals and hot water as,**  
 Ga.Coastal Plain 344.
- Nematode(s)**—*see also* Root knot nematode.  
 and usual methods of control, 781.  
 golden, of potatoes, U.S.D.A. 202.  
 meadow, on citrus, 343.  
 meadow, on tobacco, U.S.D.A. 203.  
 new, from deer, 384.  
 parasitic in sheep, identification of eggs,  
 821.  
 sheep, survival in pastures, 389.
- Nematodirus helveticus*, percentage incidence in cattle,**  
 101.
- Neodiprion***—  
*lecontei*, *see* Pine sawfly, red-headed.  
*sertifer* control, 784.  
 spp., development after hibernation in cocoon, effect of temperature, 229.
- Neohaematopinus sciurinus*, parasite of squirrel,**  
 497.
- Neolasioptera* on wheat, Ga. 654.**
- Nervous system and vitamin A deficiency,**  
 136.
- Neurospora***—  
 biochemical reactions in, genetic control,  
 151.  
*crassa*, aminobenzoicless mutant, genetic control of biochemical reactions, 180.  
*tetrasperma*, experimental induction of heritable and other alterations in, 25.
- New Mexico College notes,**  
 143, 575, 869.
- New Mexico Station notes,**  
 143, 575, 869.
- [New York] Cornell Station notes,**  
 143, 429.
- New York State Station notes,**  
 869.
- New York State Station report,**  
 287.
- Newcastle disease virus, affinity to influenza virus group,**  
 242.
- Nezara viridula*, *see* Stinkbug, southern green.**
- Niacin—*see also* Nicotinic acid.**  
 and niacin amide, suggested use of terms,  
 416.
- Nickel**—  
 absorption and excretion by man, 279.  
 arsenate, determination in treated wood,  
 154.  
 chromate, determination in treated wood,  
 154.
- Nicotiana***—  
 cytogenetical studies, 318.  
*glutinosa* and its hybrid, morphological features, 318.  
 haploids, cytogenetic studies, 466.  
*rustica* hybrid, incomplete somatoplastic sterility in, 178.  
 South American genetic groups and distribution, 25.  
 spp., and hybrids, alkaloids in, 289.  
*tabacum*, fruit setting and development, relation to growth hormones, 743.
- Nicotine**—  
 bentonite insecticides and copper fungicides, compatibility, 364.  
 formation in plants grafted on tobacco,  
 174.  
 free, in arsenical and cryolite dust mixtures, 500.  
 growing tobacco as source of, U.S.D.A. 45.  
 in tobacco, determination, modification of Official method, 590.  
 synthesis in excised tobacco roots, 744.
- Nicotinic acid**—  
 and related compounds, polarographic characterization, 732.  
 deficiency, excretion of specific fluorescent substances in urine in, 712.  
 deficiency in dogs, 668.  
 extraction and assay from animal and plant tissues, 733.

## Nicotinic acid—Continued.

- in cereal products, 556.
- in cereal products, determination, nature of interfering chromogens, 437.
- in cereals, assay, 732.
- in chick nutrition, 669.
- in foods, distribution, 136.
- in honey of different localities, 551.
- in meat, 858.
- in prepared foods, 281.
- in wheat and wheat products, 557.
- in wild rice, 857.
- increase in germinating seeds, 313.
- metabolism, 556.
- recommended terms for, 416.
- royal jelly and bee bread as source, 82.
- small quantities, determination, 203.

*Nippostrongylus muris* infection in albino rats, bio-assay of anthelmintics in, 824.

*Nitella*, increased irritability in, due to guanidine, 606.

Nitrate studies, Nebr. 15.

Nitrate studies, as related to soil moisture, Oreg. 595.

## Nitrification—

- experiments, Tex. 15.
- in Bedford silt loam, effect of potassium chloride, 306.
- threshold pH value for, Ariz. 451.

## Nitrogen—

- determination, micro-Kjeldahl, 290.
- distribution studies, 729.

## fixation—

- by *Anabaena cylindrica*, 312.
- by *Azotobacter* associated with other bacteria, 305.
- by *Azotobacter*, effect of molybdenum and vanadium, 19.
- in legumes and characters of root-nodule bacteria isolated from, 176.
- in soils by legumes, Mo. 15.
- nonsymbiotic, effect of fertilizers and season, 166.
- studies, biochemical, 461.

metabolism in plants, end products of, 315.

shortage for farm production and best use of available supply, Miss. 738.

shortage, meeting by increased winter legume production, Miss. 41.

sources and rates, Miss. 300.

supplies in wartime, Vt. 454.

Nitrogenous fertilizers, acid-forming, neutralization, relation to nitrogen availability and soil bases, 306.

Nodular worm disease of sheep, U.S.D.A. 528.

## Nodule bacteria—

- effect of mixing Ceresan-treated oats with inoculated vetch seed, Oreg. 619.
- serological studies, 741.

North Carolina Station report, 574.

## North Dakota—

- College notes, 869.
- Station notes, 429, 869.
- Station, publications of staff of, 720.

*Nosema apis* in package bees, 668.

*Nosema* disease, winter losses and queen superscedure due to, 664.

*Notocotylus stagnicolae* n.sp., life history studies, 230.

## Nursery—

- inspection, Conn.[New Haven] 499.
- inspection and quarantine, taxonomic problems in, 499.
- stock, balling, Oreg. 628.
- stock, inspection, certification, and transportation, Ky. 331.
- stock, ornamental, diseases, Oreg. 641.

## Nuts—

- culture in Missouri, Mo. 483.
- studies with, Tex. 47.

Nutgrass, control, 626, Miss. 186, 476.

Nutmeg culture, P.R. 628.

Nutrient solutions, dilute, bacterial activity in, 26.

Nutrients, application in form of sprays, N.Y.State 193.

## Nutrition—

- and food production in Great Britain, 545.

animal, *see* Animal nutrition.

contribution of amino acids to, 277.

cooperative research in, 545.

for national defense, 130, 410.

foundation, grants for, 722.

human, blood plasma ascorbic acid tests in mass studies, Pa. 715.

human, mass studies in, 131.

human, relation to vitamins in food, Kans. 701.

importance, in prenatal clinic, 410.

important for older school children, Miss. 275.

of rural population in Tennessee, 132.

of school children, improvement, 851.

plant, *see* Plant nutrition.

relation to pregnancy and lactation, 131.

relation to tooth decay, 566.

study of Virginia, seasonal survey, Va. 276.

## Nutritional—

- deficiencies in rats, pathologic aspect, 418.

status, evaluation, 410, 546.

## Oak—

live, powdery mildew of, 780.

of Central America, U.S.D.A. 201.

red, growth, effect of leaf mold v. inorganic fertilizers, 57.

stump sprouts, origin and development, relation to likelihood to decay, 639.

white, acorns, germinating, respiration studies, 316.

willow, acorns as source of vitamin A activity, 877, 803.

## Oat(s)—

- and oatmeal, composition and nutritive value, 407.

and pea hay and silage, average acre yields and production costs, Alaska 617.

average acre yields and production costs, Alaska 617.

## Oat(s)—Continued.

breeding, Ark. 755, Ga. 617, Ga.Coastal Plain 325, Kans. 618, Mont. 618, Nebr. 41, Okla. 755, Oreg. 619, Tex. 42, U.S.D.A. 616.  
 composition, factors affecting, 21.  
 crown rust resistance, breeding for, relation to winter pasture usage, Ark. 768, culture tests, Ga.Coastal Plain 325, Miss. 325, Mont. 619, Tex. 42.  
 disease, American, found in western Anatolia, 771.  
 disease resistance in, breeding for, Kans. 640.  
 disease-resistant and hardier, breeding, results, 484.  
 downy mildew disease, 348.  
 fertilization in Yazoo-Mississippi Delta, Miss. 41.  
 fertilizer tests, Ga. 617, Ga.Coastal Plain 325, Kans. 618, Tex. 42.  
 for fattening steers, Okla. 797.  
 for grain and winter pasture, variety tests, Tex. 42.  
 gray speck production in purified sand cultures, 487.  
 ground, quality on Massachusetts markets, Mass. 798.  
*Helminthosporium* leaf spot in Arkansas, U.S.D.A. 343.  
 hogging off, Ga.Coastal Plain 373.  
 in dark and light, development of xylary elements in first internode, 747.  
 increased yields by lime and phosphate, N.C. 446.  
 manganese deficiency disease, 168.  
 nutrients in, effect of soil fertility, Ind. 737.  
 Pioneer and Wintok winter-resistant, U.S.D.A. 616.  
 plant juice, ovulating factor in, 91.  
 planting tests, Nebr. 41.  
 Rangler, resistant to crown rust and smut, U.S.D.A. 616.  
 resistant to cold and disease for North Carolina farmers, N.C. 473.  
 rolled, packaged in cardboard cartons, cause of infestation by confused flour moth, 782.  
 seed, response to hormone treatment, N.Y.State 190.  
 seeding, rates and dates, Miss. 41.  
 smut(s)—  
   heavy annual loss from, prevention, Miss. 63.  
   resistance, breeding for, Mo. 41.  
   seed treatment for, Mont. 641.  
 stem rust, variation in reaction of Anthony variety to, 486.  
 superior varieties or strains grown by station, Oreg. 619.  
 tests for high vitamin and high chlorophyll foods and feeds, U.S.D.A. 617.  
 utilization of absorbed phosphate by, 453.  
 Utah, notes, Utah 620.

## Oat(s)—Continued.

varieties, Mich. 755.  
 variety tests, Ark. 755, Ga.Coastal Plain 325, Kans. 618, Miss. 41, 186, 325, Mo. 41, Mont. 618, Nebr. 41, Okla. 755.  
 winter resistance in, breeding for, Ark. 41.  
 yield and mineral content, effect of minor element compounds, 456.  
 yields, crop rotation v. superphosphate for, Ark. 755.  
 yields, effect of seed treatments, Mo. 50.  
 Outgrass—  
   tall, for pasture and hay, seeding practices and seeds, N.J. 187.  
   tall meadow, sowing with alfalfa to keep out "cheat" grass, Oreg. 619.  
*Oenothera*, tetraploidy, in, colchicine induced, 467.  
*Ocrophagostomum radiatum*, percentage incidence in cattle, 101.  
 Oestrogen(s)—  
   administration to castrated male rats, effect on copulatory behavior, 752.  
   effect on young of injected lactating rats, 40.  
   source, chemical composition, and richness, 40.  
 Oestrogenic activity, variables affecting estimation, 183.  
 Oestrone—  
   conversion to oestriol in vivo, 727.  
   effect on lactogen in pituitary and blood of male rabbits, 753.  
   treatment of mammary glands and teats of rabbits, effect, 470.  
 Oestrous cycle—  
   and reproduction of golden hamster, actions of sex hormones on, 753.  
   relation to oogenesis in mice, 614.  
 Ohio Station notes, 429.  
 Ohio Station report, 426.  
 Oil(s)—see also Fat(s) and specific oils.  
   ✓ bacteria attacking, 175.  
   deposit observations, 74.  
   extracted, column for stripping solvents from, 6.  
   imported, replacing with modified domestic oils, U.S.D.A. 723.  
   light petroleum, for codling moth, 869.  
   mineral, carotenoid pigments produced from, 26.  
   mineral, suitability as mosquito larvicides, tests for, 509.  
   packing, for sardines, analyses, Me. 545.  
   promoting oxidation of, 433.  
   seed, recovery from press cake, U.S.D.A. 723.  
   sprays and other dormant treatments containing oil, 220.  
   sprays, performance, effect of temperature and rainfall, N.Y.State 785.  
   vegetable, U.S.D.A., 723.  
 Oilseed meals, expanding uses of, U.S.D.A. 723.

- Oiticica* nut, curculionid pests of, 505.  
 Oklahoma College notes, 429.  
 Oklahoma Station notes, 288, 429.  
 Oklahoma Station report, 867.  
 Okra mosaic disease, nature of, 779.  
 Oleomargarine and butter, comparative nutritional value, 701.  
*Oleiscampe pikonemae* n.sp., description, 512.  
 Olive(s)—  
   aerial root system of, significance, 316.  
   dehydration of, 850.  
   experiments of 1940-41 season, 295.  
   fruits, disease of, 493.  
   nutritive deficiencies in, diagnosis, 493.  
   tree, root system, 316.  
*Oilula* spp., new and interesting from Mt. Shasta, 601.  
*Omphalia flavida* on coffee, 778.  
*Onchocerca cervipedis* in deer of northern Rocky Mountain region, 245.  
*Oncideres cingulatus*, see Twig girdler.  
 Onion(s)—  
   culture, Mont. 628.  
   dehydration tests, 849.  
   fertilizer tests, R.I. 326.  
   fly, black, bionomics and morphology, 277.  
   growth and yield, effects of partial defoliation at transplanting time, U.S.D.A. 47.  
   leaf blight, Tex. 60.  
   maggot studies, Oreg. 655.  
   neck rot prevention in cold storage, Tex. 60.  
   production in northern Indiana, economic aspects, Ind. 838.  
   rotations for, R.I. 331.  
   seed production, Idaho 333.  
   seed stocks, tests, N.Y.State 191.  
   seedbed diseases, control, 491.  
   seedlings, *Ditylenchus dipsaci* in, pathogenesis, 647.  
   thrips on carnations in greenhouses, control, Wash. 503.  
   thrips studies, Tex. 73.  
   variety tests, Ga.Coastal Plain 331.  
   virus disease in Portugal, 495.  
   weed control in, [N.Y.]Cornell 333.  
 Oogenesis, relation to oestrous cycle in mice, 614.  
*Oospora lactis*—  
   cultures, growth, effect of acidity and temperature, 91.  
   growth rate, 96.  
 Ophthalmia—  
   contagious, of sheep, 528.  
   in blue fox pups, Alaska 652.  
   periodic, of horses, U.S.D.A. 97.  
   periodic, studies, U.S.D.A. 676.  
 Orange(s)—  
   composition and time of maturity, effect of fertilizer practices, 198.  
   composition, relation to K deficiency, U.S.D.A. 627.  
   effect of growth substances on solids and acid contents, 190.  
 Orange(s)—Continued.  
   Florida, carotenoid pigments in juice, 197.  
   juice, canned, flavor deterioration in, prevention, 207.  
   juice concentrate, improved, 207.  
   juice, packaged, causes of darkening, 441.  
   leprosis, 358.  
   marmalade of high vitamin C content, improved, 156.  
   Pineapple, preharvest sprays for reducing dropping, timing, 190.  
   tortrix control, 224.  
   trees, adjustment of yields in, fertilizer experiment, 636.  
   trees, young, bearing, growing in solution cultures, weekly nitrate absorption, 108.  
 Orcein, standardization, progress in, 607.  
 Orchard(s)—see also Fruit(s), Apple(s), Peach(es), etc.  
   Atchison experimental, Kans. 194.  
   border trees, relative yields, 632.  
   cover sites, relation to low-temperature injuries, Pa. 628.  
   diseases, dormant sprays for, Miss. 479.  
   fertility problem in wartime, Pa. 334.  
   fertilizers, need of wise use in wartime, Pa. 628.  
   grass for pasture and hay, seeding practices and seeds, N.J. 187.  
   home, need for pruning, fertilization, and spraying, Miss. 479.  
   in eastern Nebraska, supplemental water for, Nebr. 47.  
   insects of Pacific Northwest, control, U.S.D.A. 784.  
   mites and mealybug problem, 230.  
   on sandy soils, legume program, Mich. 766.  
   site and mulch treatment, relation to winter injury, Kans. 628.  
 soil(s)—  
   management, Nebr. 47.  
   movement of potassium fertilizer in, Ohio 331.  
   porosity, effect on root behavior, Mich. 596.  
   under sod, mulch, and cultivation, aggregation of, 596.  
   sources of N for, Pa. 628.  
   work, careful planning to alleviate labor shortage, Colo. 765.  
 Orchid—  
   fruits, correlation of growth with internal development, 33.  
   seeds, sterilization, aerosol-hypochlorite technic, 496.  
   soft rot, cause, 649.  
*Orechopeas wickhami*, parasite of squirrel, 497.  
 Oregon Station report, 720.  
 Organic acids, ether soluble, role in salt absorption by plants, 462.

- Organic matter—**  
 and montmorillonite, interaction between, 455.  
 changes in during decomposition of compost heaps, 597.  
 effect on properties of Berks silt loam, 185.  
 in soil, effect of texture of erosion material, N.Y.State 160.  
 incorporated, and organic mulches, effect on erosion and soil structure, 185.  
 incorporated, v. mulches, effect on soil and moisture conservation, 185.  
 need of Paulding County soils for, Ohio 301.  
 of soil, fractionation, relation to quality, 597.  
 of soil, studies, 185, Nebr. 15.
- Orius insidiosus*, predator on cotton insects, 72.

  - tests, Ga., 627, Ga Coastal Plain 331, Miss. 191
- virus disease studies, developments in, 357.
- vitamins in, 627.
- wart, a virus disease, 648.
- wartime marketing problems of, Ark. 841.
- wavy-leaf character in, inheritance, 318.
- X disease—
  - control by killing chokecherry, 215
  - N.Y.State 215.
  - summary, 215.
  - western, 357.
- leachtree borer—
  - control, Miss. 369, N.C. 476.
  - control in New York State, 363.
  - control, insecticides for, N.Y.State 785.
  - control, new materials for, Ohio 362.
  - effect on trees of ethylene dichloride emulsion treatment for, 782.
- Peafowl, sex inversion in, 323.
- Peanut(s)—
  - and cotton in rotation, need of more K for, U.S.D.A. 617.
  - and milk proteins in diet of rat, comparison, Ga. 699.
  - as feed for pigs, Ga. 666.
  - as soil-depleting crop, N.C. 473.

## Peanut(s)—Continued.

- breeding, Ga. 617, Ga.Coastal Plain 325, Tex. 42.
- culture experiments, Ga.Coastal Plain 325.
- diseases, studies, Tex. 59, U.S.D.A. 640.
- effect of handling in field on quality of nuts and oil, Ga. 579.
- emergence improvement by seed treatment, N.C. 485.
- fertility indices for, comparison. 185.
- fertilizer tests, Ga.Coastal Plain 325, Tex. 42.
- flour for human consumption, 699.
- hogging off, Ga.Coastal Plain, 373.
- leaf spot, control, Ga.Coastal Plain 325.
- leaf spot, fungicidal dusts for, 484, Ga. 640, N.C. 485.
- need of increased production and yields, Miss. 755.
- nutrient absorption by, time and rate, 185.
- nutrient deficiency symptoms in, N.C. 473.
- on vine and sweetpotato meal as milk-producing feed for dairy cattle, Ga. 671.
- or peanut butter in human diet to improve protein value and vitamin B complex in, Ga. 699.
- production on Coastal Plain, Ga.Coastal Plain 188.
- proteins, Ga. 579.
- proteins, threonine, serine, cystine, and methionine in, 580.
- response to lime and K, N.C. 473.
- root, stem, and fruit decay associated with fungi, N.C. 485.
- seed treatment, 484, Ga. 640.
- spacing tests, Ark. 755.
- utilization, Ga. 579.
- varieties and strains, yield differences, N.C. 473.
- varieties, large and small-seeded, yield and shelling properties, 186.
- variety tests, Ark. 755, Ga. 617, Ga.Coastal Plain 325.
- wartime production, seed treatment as aid in, 209.
- yield increase due to early planting and seed inoculation, N.C. 473.

## Pear(s)—

- Bartlett, preharvest drop, sprays for control, 338.
- Bartlett, softening and soluble solids in, effect of soil moisture, 634.
- cull dried, feeding value for hogs, Oreg. 666.
- fire blight in Florida, U.S.D.A. 58.
- fruit setting and progeny fertility in, Vt. 476.
- juice, preparation and processing, 156.
- leaf spot control, spraying for, Mo. 59.
- orchards, border trees, relative yields, 632.
- pollination, Oreg. 628.

## Pear(s)—Continued.

- pollination, position on cluster, and set, interrelation, Vt. 52.
  - production under differential soil moisture treatments, relation to pruning, Oreg. 628.
  - psylla control, dinitro insecticides and oil sprays for, N.Y.State 785.
  - residue, dried, for pig feeding, 376.
  - scab and storage rot, control, Oreg. 641.
  - thrips in prune orchards, control, 74.
  - time interval between full bloom and fruit maturity, 334.
  - trees, boron deficiency in, 492.
  - variety tests, Ga.Coastal Plain 331, Miss. 191.
  - virus stoney pit disease, Oreg. 641.
- Peats in New Jersey, nature and properties, 597.
- Pecan(s)—
- fertilizer and cultural needs, Ga.Coastal Plain 331.
  - growth, yield, and quality, effect of fertilizer and time of application, 54.
  - insects in middle Georgia, 363.
  - new, Cape Fear, development, N.C. 476.
  - nut casebearer studies, Tex. 73.
  - rosette, soil applications of zinc sulfate for control, 778.
  - trees, delayed foliation, 636.
  - trees treated with indolebutyric acid at transplanting, root and shoot production by, 627.
  - trees, zinc sulfate treatment, improved method and duration of effect, 778.
  - variety tests, Ga.Coastal Plain 331.
- Pectin(s)—
- and pectic enzymes, chemistry of, N.Y. State 272.
  - decomposition by intestinal bacteria, 569.
  - regulating methoxyl in methods, 432.
  - uses in wartime, N.Y.State 735.
- Pectinophora gossypiella*, see Bollworm, pink.
- Pellagra, story of treatment with nicotinic acid, 705.
- Penicillin—
- activity in vitro, 388.
  - chemotherapeutic activity, 388.
  - extraction from *Penicillium notatum*, 388.
  - mechanism of action, 388.
  - new antiseptic agent from corn sugar, U.S.D.A. 723.
  - nitrogenous character, 172.

*Penicillium*—

- claviforme*, antibacterial substance produced by, 600.
  - notatum*, cultural characteristics, relation to production of antibacterial substance, 460.
  - roqueforti*, growth and enzyme activity, Minn. 522.
  - spp., production of bacteriostatic substances by, 601.
- Pennsylvania College notes, 143.
- Pennsylvania Station notes, 143.
- Pennsylvania Station report, 720.

- "Penny-a-pig" program, 513.
- Pentatomids, parasites, receipt of shipments of, P.R. 656.
- Penttilia castanea*, control of scale insects by, P.R. 655.
- Peony root knot, failure of hot-water treatment, Ohio 344.
- Pepper(s)—  
 black, culture, P.R. 623.  
 composition of artificially produced parthenocarpic and normal fruits, 764.  
 dehydrator for, Colo. 849.  
 diseases, virus, 209.  
 growth and yield, effects of partial defoliation at transplanting time, U.S.D.A. 47.  
 maggot, studies, Ga. 655.  
 Perfection pimiento, time of flower primordia differentiation, effect of photoperiod, 477.  
 pimiento, transplanting solutions for, Ga. 627.  
 pungency in, chemical test, Mich. 630.  
 seed stocks, tests, N.Y.State 191.  
 weevil in California, control, 79.  
 weevil studies, U.S.D.A. 368.
- Peppermint oil, determination of methol in, acetyl chloride as reagent, 731.
- Perilla production tests, Kans. 618.
- Periplaneta americana*, see Cockroach, American.
- Permeability—  
 of soils to water, Nebr. 15.  
 salt accumulation, and metabolism in plants, interrelations, 314.
- Peromyscus*, aberrant ratio in, 469.
- Peronospora*—  
 genus in the Punjab, 204.  
 on soybean in Virginia, U.S.D.A. 203.  
*parasitica*, oospore production in cabbage seedlings by, 484.  
*tabacina*, cause of tobacco downy mildew, 774.
- Perosis—  
 in chicks, prevention by factors other than manganese, 377.  
 in turkey poult and choline in diet of, 807, 826.  
 in turkey poults, development and prevention, 237.  
 prevention by biotin, 669.
- Persimmon leaves and fruit, ascorbic acid in, 313, 861.
- Pest control, use of toxic polynitro derivatives in, 654.
- Pest survey and insect control, Okla. 783.
- Petroleum oils as insecticides, developments in use, 368.
- Petunia axillaris*, colchicine stimulation of seed germination, 28.
- Pheasant(s)—  
 Chinese, nesting in Willamette Valley, Oregon, 361.  
 pH of digestive tracts of, 236.  
 ringed-neck, *Heamita* sp. from, 686.
- Phenacoccus*—  
*aceris* control by dormant sprays, 223.  
 spp. of northeastern America, 223.
- Phenol(s)—  
 disinfectants, synthetic, 243.  
 in meat and fat, estimation, 589.
- Phenothiazine—  
 as anthelmintic for sheep, 245.  
 colorimetric determination, 731.  
 effect on blood of fowl, 250.  
 effect on hemoglobin in fowls, Kans. 676.  
 feeding to poultry in various amounts, effects, 250.
- Phenylalanine, metabolism, role of ascorbic acid in, 419.
- Phenylthiocarbamide, ingestion, graying of hair produced by, 412.
- Phialophora malorum* and *Sporotrichum malorum*, relation, 492.
- Phomopsis—  
*cinereascens* on fig branches in Brazil, 493.  
*occulta* and *P. juniperovora*, taxonomy, distribution, and pathology, 779.
- Phormia regina*—  
 as transmitter of *Endamorba histolytica*, 370.  
 seasonal distribution, 81.
- Phosphate(s)—  
 amperometric determination with uranyl acetate, 290.  
 and lime for pasture, Miss. 739.  
 comparison, Tex. 599.  
 deficiency in Idaho soils, determination by *Azotobacter* plaque test, 166.  
 determination of sodium in presence of, 586.  
 experiments, Ark. 15, Miss. 159.  
 fertilizers, field experiments with, R.I. 167.  
 fixation in soils, 22, 167.  
 reserves of Utah, revised estimate, Utah 455.  
 waste pond, compared with rock phosphate and superphosphate as fertilizer, 456.
- Phospholipids—  
 in dairy products, 7.  
 oxidation in presence of ascorbic acid and carcinogenic chemicals, 584.
- Phosphoric acid—  
 contents of sewage sludges, N.J. 738.  
 in soil extracts, determination, 150.
- Phosphorus—  
 absorption from rock phosphate, effect on composition and dry weight of corn, 21.  
 analysis of plant material, 291.  
 and lime as primary soil needs, Pa. 596.  
 compounds, organic, dephosphorylation by soil catalysts, 598.  
 deficiency, preventing normal succession on areas of Bull Run Mountain in Virginia, 311.  
 dietary absorption by rat, effect of aluminum, 854.

## Phosphorus—Continued.

- economy in animal organism, 705.
- in expressed vegetable juice, 559.
- inorganic, concentration in whole blood of dairy cattle, 94.
- organic, availability to plants and dephosphorylation, 314.
- radioactive, use in translocation studies, 744.

*Photobacterium* spp., studies, 457.

## Photomicrograph, still and movie, technic for obtaining accurate exposure times, 782.

## Photoperiodism—see also Day length.

- accompanying autotetraploidy, 34.

## Photosynthesis—

- in forest trees, Vt. 483.

experiments with dried pear residue, 376.

finishing, rations for, Miss. 231.

goiter in, prevention with iodized salt, Mont. 676.

ground soybean hay for, U.S.D.A. 665.

growth rates at different ages, genetic and environmental correlations, 610.

helminth parasites of in Queensland, 529.

inbred line, development from crossbred foundation, 610.

inbred lines, experimental design for testing, 611.

inbreeding and improvement, Mo. 34.

inheritance in, study by breed colors and morphological conditions, Mo. 34.

length of feeding period, economic analysis, 393.

low agglutination reactions in unbred virgin gilts, Mo. 99.

market, protein-mineral-vitamin supplements to barley rations, 668.

measures of growth rate for use in selection, 516.

nicotinic acid for, Mo. 84.

nutrition, vitamin B<sub>6</sub> in, 516.

nutritional inadequacy of beet molasses rations, Utah 516.

oat and pea pasture with and without grain for, Alaska 666.

on peanut ration, deficiency symptoms in, Fla. 87.

on rape pasture, soybean meal for, Pa. 666.

on Sudan grass pasture, fattening, supplements for, Nebr. 84.

parasites of and treatment for removal, U.S.D.A. 676.

pasturing annual crops with, Mont. 610.

photosensitization produced by phenothiazine, 245.

Poland China, variance of 180-day weights, factors affecting, 182.

potassium requirements in feed, Ga. 666.

raising in Arizona, Ariz. 668.

raising, self-feeder and movable automatic waterer as labor savers in, Colo. 834.

rations, proteins in, U.S.D.A. 665.

runts, gains on special rations, Mo. 84.

salt tolerance and salt poisoning, U.S.D.A. 98.

**Pig(s)—Continued.**

sensory neuron degeneration in, control, 799.

skim milk in rations, Ark. 88.

skim milk, whey, and pasture for, Ark. 797.

sorghum grains for, Nebr. 84.

soybean feeding methods, 797.

suckling, early infections with helminth parasites, 384.

suckling, management, Ga.Coastal Plain 373.

sugar beet molasses for, Utah 668.

supplements to corn and tankage for, Pa. 666.

transportation types, average rates charged for, Ohio 394.

vitamin A and carotene requirements, 798.

vitamin A requirements, Tex. 85.

vitamin requirements, 514.

Wessex Saddleback, color variation in, relation to conformation and usefulness, 310.

wheat as feed for, Utah 667.

Pigeon fly, U.S.D.A. 98.

**Pigeon(s)—**

directed mutation in, possible case of, 749.

immunogenetic studies of species, 37.

pH of digestive tracts of, 236.

vitamin requirements, Mo. 84.

Pigments, pure, distribution between immiscible solvents, 435.

**Pikonomia—**

sawflies, new *Olesicampe* parasite of, 511.

spp., development after hibernation in cocoon, effect of temperature, 229.

**Pilchard meal—**

and soybean meal mixture, gross values, 236.

feeding value, effect of heat and moisture, 374.

Pillbugs, control, 501.

Pimientos, *see* Pepper(s).

Pine(s)—*see also* White pine.

beetle, mountain—

native predators, biology, 367.

predators, laboratory propagation of, 791.

beetle, western, control through tree selection, 659.

blister rust, *see* White pine blister rust.

direct seeding, effects of stratification, 200.

eastern, canker of, associated with *Atropella tingens*, 780.

fused needle disease, 496.

gall-forming *Peridermium* on, experimental autoecism and other studies, 71.

in east-central Alabama, natural reproduction, Ala. 768.

jack, red-stained ties under service conditions, decay in, 216.

## Pine(s)—Continued.

- jack, seedlings, effect of thiamin and niacin on growth, 483.
  - loblolly, buttressed trunks, effect of annual spring fires, 639.
  - loblolly, management in pine-hardwood region, 56.
  - loblolly, yield of even-aged stands in Louisiana, 200.
  - lodgepole, interception of rainfall by, 445.
  - lodgepole, stands, effect of cutting on rainfall interception, 639.
  - longleaf, sites, variations in fire danger factors, 202.
  - of Arkansas, dendrochronology, 201.
  - plantations in Piedmont section of Georgia, ice damage to, 343.
  - ponderosa, region of Pacific slope, fire as ecological and silvicultural factor in, 639.
  - red, saplings, height related to density 200.
  - sapwood, *Trichoderma lignorum* in, effect, 216.
  - sawfly control, 784.
  - sawfly, red-headed, mortality of young pines defoliated by, 229.
  - sawfly, red-headed, on seedling pines, 664.
  - Scotch, disease due to *Diplodia pinea*, 651.
  - Scotch, planting stocks, tests, N.Y.State 200.
  - seedlings, growth in water culture, effects of boron concentrations, 496.
  - slash, studies with, Tex. 47.
  - small crowned ponderosa, value in reserve stands, 342.
  - Virginia, cankered, undescribed *Atropellis* on, 359.
- Pinus* species, differentiation by colorimetric tests of their pitch, 638.
- Pipe discharges, measuring, use of current meters in, Colo. 829.
- Piricularia oryzae*, notes, Ark. 769.
- Platol can-bearer control, Pa. 652.
- Pituitary (ies)—
- anterior—
    - extracts, effect on poultry, 321.
    - hormones, extraction and separation, Mo. 34.
    - of cattle and female rabbits, prolactin in, 91.
    - of rabbit and guinea pig, lactogen in, Mo. 34.
  - cystic, in young cattle with vitamin A deficiency, 375.
  - glands of albino mice compared to other species, lactogen in, 471.
  - glands of female rats treated with antigonadotropic serum, increase in gonadotropic content, 39.
  - glands of male rat, gonadotropic hormone in, effect of ascorbic acid, 91.
  - hormones, comparative assays for mam-mogenic growth factor, 614.

## Pituitary (ies)—Continued.

- interstitial-cell-stimulating hormone—
    - biological properties, 39.
    - standardization methods, 39.
  - of livestock, mammogen content, Mo. 84.
  - of pseudopregnant rabbits, lactogen in, 754.
  - of rabbit, fat metabolism hormone of, Mo. 34.
  - of swine, gonadotropins of, 38.
  - rat thyrotropic hormone in, Mo. 34.
  - sheep, separation of adrenotropic hormone from, 616.
  - weight of albino rat, relation to body weight, 321.
- Plane tree, London, canker stain control, N.J. 651.
- Planning Authority, Central, of Great Britain, U.S.D.A. 405.
- Plant(s)—*see also* Flora(s) and Vegetation.
- absorption of inorganic nutrients by, relation to pH, 603.
  - and soil research, Federal-State cooperation in, 15.
  - ants and termites, ecological relations, 311.
  - aquatic, photosynthesis of, 316.
  - as potential sources of rubber, testing, U.S.D.A. 627.
  - ascorbic acid in, physiological activity, 29.
  - beds, chloropierin as disinfectant for, 345.
  - biochemistry and physiology, 312.
  - biology, textbook, 126.
  - breeding possibilities for southern Florida, 197.
  - bugs control in citrus groves, 503.
  - cancerous neoplasm of, 204.
  - carnivorous, 601.
  - carotene determination in, 152.
  - carotene development in, 232.
- cell(s)—
- accumulation of salt and permeability in, 314
  - division and growth, test of chemicals other than colchicine for effect on, N.Y.State 193.
  - walls, dispersion of cellulose strands in, 317.
- chromosomes, *see* Chromosome(s).
- communities of—
- Piedmont, N. C., ecological analysis, 311.
  - southeastern coastal plain, ecological problems, 311.
  - Welaka area, Florida, 461.
- copper deficiency in, 60.
- deficiencies, relation to soil composition, Tex. 21.
- desert, *see* Desert.
- diagnosing mineral deficiencies, importance of determining concentration of C in plant extracts, 484.
- dicotyledons commonly cultivated in Brazil, keys for, 310.

## Plant(s)—Continued.

disease(s)—*see also* Fungi(us) and different host plants.

and control, recent outstanding cases in South Dakota, 208.

control, national policy, 484.

control, papers on, 58.

host-parasite check-list revision, U.S.D.A. 58, 202, 640.

in Canada, check-list, 344.

in Ceylon, 485.

in Maine, additions to, U.S.D.A. 58.

in Massachusetts, U.S.D.A. 203.

in Nebraska prior to July 18, 1942, U.S.D.A. 58.

in U.S. prior to 1917, estimates of losses from, U.S.D.A. 58.

nature and prevention, 202.

nature, cause, and control, Miss. 203.

nonparasitic, in Chile, 485.

papers on, 640.

parasitic, in Chile, 485.

recorded in Scotland, 203.

surveys, prevention of losses by, Okla. 769.

distribution records of Indiana, 310.

drug, *see* Drug plants.

effects of prolonged rotation on horizontal klinostat, 170.

exchange, technic of, U.S.D.A. 768.

flower-bud initiation, effect of flower-producing hormones, Mo. 47.

flowering composites, photoperiodic after-effects in, 32.

fluorine content, effect of fertilizer treatments, 456.

food availability in alkaline-calcareous soils, Ariz. 20.

grafted on tobacco, formation of nicotine in, 174.

greenhouse culture, Okla. 763.

greenhouse, gas injury, Kans. 628.

groups, temperature reaction, mutation, and geographical distribution in, 26.

growing in quartz sand substrate, availability of adsorbed ions to, 455.

growth and differentiation, symposium, 33.

growth and nitrogen balance of soils, effect of legumes and free-living organisms, Kans. 595.

growth and yield, effect of insecticides added to soils, 501.

growth, effect of irrigating soils with waste sulfate liquor, Oreg. 595.

growth in quartz sand, effect of soil and peat admixtures, 738.

growth substance(s)—

applications in horticulture, 190.

preparation and use, U.S.D.A. 46.

research, critical study of *Avena* test and extraction methods used in, 456.

## Plant(s)—Continued.

growth substance(s)—continued.

response, interrelation of organic materials in, 27.

substituted phenoxy and benzoic acid, 174.

vitamins as, 25.

growth under controlled conditions, effect of pH on, 603.

hormones, *see* Plant growth substances.

house, insects infesting, Mich. 656, 784.

hybrids, mock-dominance and hybrid vigor in, 177.

incompatibility in, physiology, 313.

induced evolution in, 25.

juice, frozen, ovulating potency in rabbit, 752.

juice preparations, orally active sex maturity factor(s) in, 91.

kingdom, modern classification, 309.

life, physiological activity of ascorbic acid in, 713.

material(s)—

gonad-stimulating, U.S.D.A. 670.

identification, U.S.D.A. 627.

imported for testing, U.S.D.A. 808.

phosphorus analysis, 291.

strategic, importation, U.S.D.A. 627.

use as orchard cover crops, Pa. 628.

medicinal, of Navajo Indian, 460.

metabolism iron-manganese relation in, 645.

mineral pattern of stems, determined by microincineration, 314.

native, adaptability for stabilization of blowing sand areas, Tex. 25.

nectar and pollen, Oreg. 795.

newly introduced, testing and propagation, P.R. 629.

nitrate content, factors affecting, 315.

nitrogen metabolism in, end products of, 315.

nutrition—

and hydrogen ion, 209, 604.

minor elements in, Oreg. 595.

physiological studies in, 171, 744.

zinc in, 456.

ornamental—

diseases, Oreg. 641.

propagation with growth substances, Ohio 331.

seed treatment studies, 484.

studies, Tex. 47.

pathology in England and Wales, organization for, 203.

perennial, for North Carolina, N.C. 342.

perennial, variety tests, Kans. 628.

photosynthesis, *see* Photosynthesis.

poisonous—*see also specific plants.*

in Davis Mountains, Tex. 99.

of New South Wales, 526.

to livestock, Calif. 526, U.S.D.A. 97, 676.

propagation by grafting and budding, Mo. 332.

## Plant(s)—Continued.

- resources of Honduras, 310.
- respiration, *see* Respiration.
- salt absorption and accumulation by, biochemistry, 462.
- sand culture methods, 314.
- species, temporary establishment on Canton Island, 73.
- stand on muck soil, relation to midsummer seeding, Ohio 331.
- stems, longitudinal splits in, causes of regeneration after, 171.
- sugar in, effect of cations (K, Na, Ca) on conversion, 604.
- survey of Texas, Tex. 25.
- susceptible and resistant to root knot, 781.
- suspected toxicity, feeding tests to determine, Tex. 99.
- tanning, production of substitutes for, U.S.D.A. 627.
- tests for tannin, Tex. 25.
- tissue(s)—
  - auxin extraction from, 462.
  - carbohydrates in, determination methods, Mo. 47.
  - cultures, 463.
  - cultures, new technic in experimental science, 25.
  - rubber in, new method for determination, N.Y.State 767.
  - tests, relation to fertilizer needs, N.Y.State 191.
- transplanted, survival, effect of partial defoliation, U.S.D.A. 47.
- treatment with synthetic growth substances, Ohio 46.
- vascular, of Ohio, additions to revised catalog, 311.
- viruses and crystallography, 204.
- viruses, isolation and crystallization by hydrophilic colloids, 346.
- viruses, preserving in vitro by simplified lyophile apparatus, 210.
- viruses, purification and properties, Mo. 50.
- volunteer, ring rot in, 209.
- water culture, fertilizers for, Tex. 599.
- woody, *see* Woody.
- Plasmodium gallinaceum*, mosquito-borne, immunization of fowls against, 391.
- Platinum chloride, effect on bean and tomato, 462.
- Platynota stultana*, life history and control on carnation, 79.
- Platyopocilus maculatus* populations, frequencies of dominant genes in, 749.
- Platyptilia* spp. of economic importance in California, 506.
- Plecoptera, North American, studies, 658.
- Pleospora* spp., new and interesting from Mt. Shasta, 601.
- Pleuropneumonia, bovine, developmental cycle of organism and related microbes, 527.
- Plodia interpunctella*, *see* Indian-meal moth.

## Plow(s)—

- draft increased by pressure on landside, Pa. 688.
- value of stop-hitches for, Pa. 688.
- Plum(s)—
  - aphid, mealy, new materials for control, Calif. 788.
  - beach, composition and use, 440.
  - beach, propagation by cuttings, 339.
  - canker resistance in, varietal rating, 484.
  - curculio—
    - Jarring and dichloroethyl ether for control, 367.
    - notes, Mont. 655.
    - on peach, control, 654.
    - sprays for, Pa. 652.
    - studies, Tex. 73.
  - fertilizer tests, N.Y.State 193.
  - gouger, notes, Mont. 655.
  - juice, preparation and processing, 156.
  - Lombard, latent virosis on, U.S.D.A. 343.
  - preparing for frozen food lockers, 700.
  - variety tests, Miss. 191.
- Plume moths of economic importance in California, 506.
- Plutella maculipennis*, *see* Diamondback moth.
- Plywood for grain bin construction, 259.
- Pneumococci, bacteriostatic effect of sulfonamide drugs on, quantitative determination, 526.
- Pneumoencephalitis in poultry, studies, 824.
- Pneumonia—
  - atypical, infectious agent from, transmissible to cotton rats, 525.
  - calf, cause, and effectiveness of sulapyridine in, Pa. 676.
  - calf, etiology and pathology, 682.
  - progressive, or lungier disease of lambs, Oreg. 676.
- Poa pratensis*—
  - and its hybrid, cytogenetic studies, 180.
  - nematode infestation in Nova Scotia, 209.
- Podapolipus*, acarine parasites of in South Africa, 658.
- Pogonomyrmex occidentalis*, damage to highways by, 510.
- Poinsettia, bacterial disease, 496.
- Poison ivy control by spraying, 331.
- Poisonous plants, *see* Plants, poisonous, and specific plants.
- Polarography, quantitative factors in, 5.
- Polioencephalitis, Wernicke's hemorrhagic, of man, counterpart of Chastek paralysis in foxes, 248.
- Pollen(s)—
  - composition of, 82.
  - required by colony of honeybees, 83.
- Polychrosis viteana*, *see* Grape berry moth.
- Polymers, high, synthetic and natural, textbook, 577.
- Polyploidy—
  - and relation of mitotic disturbances to X-ray dosage, 35.
  - induction in crop plants, 179.

- Polyporaceae**, transformation of basidia, moisture relation as determinant factor, 770.
- Popcorn**, hogging off, Ga. Coastal Plain 373.
- Popillia japonica*, see Japanese beetle.
- Poplar**, white, significance in Maryland, 461.
- Poppy**, white, growth and development, effect of day length, 170.
- Population**—  
 adjustment to rural resources in Missouri, Mo. 124.  
 and labor movements, keeping track of, U.S.D.A. 835.  
 changes of incorporated hamlets and villages, size as factor in, 696.  
 groups, nutrition survey, 546.  
 growth in Washington, Wash. 541.  
 increase rate, decrease of, Pa. 697.  
 migration, interstate, and county finance in California, U.S.D.A. 840.  
 migration, wartime, from rural Spanish-speaking villages of New Mexico, 843.  
 rural, of Missouri, resources, Mo. 124.
- Pork**—  
 changes in, during freezing and storage in frozen state, Ind. 848.  
 curing and storage, Alaska 666.  
 muscle, dried autoclaved, effect on pregnant rats, 273.  
 production, confinement system for, 800.  
 production, home, 800.  
 research program in Canada, 130.  
 sausage, seasoning in, Kans. 606.
- Porphyrin** nature of blood-caked whiskers of pantothenic acid deficient rats, 284.
- Porthetria dispar*, see Gypsy moth.
- Potash**—  
 available to crops unless lost by erosion, Miss. 453.  
 fertilization, crop response to, relation to available potassium, 453.
- Potassium**—  
 absorption in soils in nonreplaceable forms, 23.  
 determination in fertilizers, 7.  
 fixed, availability, affected by freezing and thawing, 22.  
 in animal nutrition, 134.  
 quick-test technics for, 149.  
 relation to soils and plant nutrition, Oreg. 595.
- Potato(es)**—  
 apical leaf speck, 351.  
 bacterial ring rot, diagnosis, 643.  
 bacterial ring rot situation in United States, 623.  
 beetle, Colorado, Nebr. 73.  
 blight, early, U.S.D.A. 58.  
 blight, early, in Ecuador, 351.  
 blight, late—  
   in Nebraska, U.S.D.A. 202.  
   in Oregon, early appearance, U.S.D.A. 640.  
   reports on, U.S.D.A. 58.
- Potato(es)**—Continued.  
 blight, late—continued.  
   situation in Upper Mississippi Valley, U.S.D.A. 848.  
   studies, U.S.D.A. 58.  
 blight-resistant strains, tests, Pa. 619.  
 breeding, Miss. 186, Nebr. 41, Oreg. 619, U.S.D.A. 616.  
 bulk handling, Idaho 259.  
 bulk storage to save burlap costs, Colo. 867.  
 Central and South American, for improvement of European and North American stocks, 25.  
 certification work, Ga. 617.  
 culture tests, Alaska 617, Mont. 610, Tex. 42.  
 dehydration tests, 840.  
 dehydrator for, Colo. 849.  
 disease(s)—  
   and insect control by breeding, 622.  
   and pests in Chile, 351.  
   control in Brazil, 773.  
   in Panama, 648.  
   in peat soils in California, survey, 63.  
   in State, N.C. 485.  
   main virus, in Victoria, 210.  
   new, in Vincentown, N. J., symptoms, 352.  
   studies, Nebr. 59.  
   virus, review, 643.  
 early, production, 623.  
 eelworm disease, 352.  
 effects of fertilizers on chemical constituents, Alaska 617.  
 ✓fertilizer tests, Alaska 617, Kans. 618, Okla. 756, R.I. 326, Tex. 42.  
 ✓fertilizers, Mich. 756.  
 ✓fertilizers, replacement of superphosphate in, U.S.D.A. 617.  
 flea beetle(s)—  
   control, 498.  
   life history and habits in western Nebraska, 700.  
   studies, Nebr. 73, Oreg. 655.  
 fruit setting in, 761.  
 growth and maturity, effect of treble superphosphate on, Alaska 617.  
 heat and drought endurance studies, Nebr. 41.  
 hollow heart, effect of foliage removal and shading, 64.  
 hollow heart, histological study, 64.  
 improvement, aid of exploration in, 748.  
 in storage, effect of humidity and temperatures at various periods, Nebr. 41.  
 inoculation tests for resistance to *Phytophthora*, 773.  
 Kansas, cold storage studies, Kans. 623.  
 Kansas, distribution, 623.  
 Kansas, storage conditions for, 623.  
 labor needs for, Mich. 756.  
 late-crop, maintaining quality in retail markets, Oreg. 842.

## Potato(es)—Continued.

late-crop, marketing, Oreg. 121.

leaf roll studies, Vt. 485.

## leafhopper—

as alfalfa pest, U.S.D.A. 658.

as hop pest, N.Y. State 218.

feeding on apple leaves, effect on photosynthesis and transpiration. 214.

Intermountain, suggested name, 75. studies, Nebr. 73.

trap-light studies, 75.

meal, feeding value for sheep, Ga. 666

mosaic, mild forms, effects, 60.

nematode, scab, and virus problems, Oreg. 641.

net necrosis in, 644.

planting, spraying, and pH range tests, R.I. 326.

## production—

and marketing in State, R.I. 394.

dusts v. bordeaux spray for, 64.

in Southern States, U.S.D.A. 189.

on Cumberland Plateau, Tenn. 44.

psyllid, notes, Mont. 655, Nebr. 73.

quality, relation to fertilization, Ohio 326.

research, 623.

resistant to leafhoppers, development of, Ohio 362.

ring rot control, results in, 488.

ring rot disease, causal agent, transmission by insects, 72.

ring rot free seed stocks, methods for selecting, accuracy, 64.

ring rot, resistance of varieties and seedling progenies to, 64.

root eelworm, cyst population of a field over a series of years, 210.

root knot control in Ecuador, 351.

scab gardens in United States, 351.

scab pathology, Vt. 485.

scab, relation to calcium, soil reaction, and fertilizers, Va. Truck 488.

scab, relation to pH of soil, 209.

scab severity, relation to fertilizers, 644.

seed, development of virus diseases in basic strains, Vt. 485.

seed piece decay, prevention, 65.

seed stock testing for virus disease, sample size and reliability, 488.

seed stocks, prevention of ring rot infection in, 623.

selection for institutions, quality and economy in, 699.

self- and cross-incompatibility in, genetic nature, 179.

sickness, effect of trace elements, 209.

sprouts for mass propagation of black scale, 504.

starch, and derivatives, uses for, U.S.D.A. 723.

starch, physical properties and relation to culinary quality of potatoes, 699.

stem end browning in, 644.

## Potato(es)—Continued.

storage tests, Alaska 617, Kans. 618.

## storages—

cooling, control system for, N.Dak. 392.

for Michigan, Mich. 691.

types, temperature studies, N.Dak. 259.

sugar in, factors affecting effect of CO<sub>2</sub> on, 44.

sulfur injury to, Tex. 73.

superior varieties or strains grown by station, Oreg. 619.

top necrosis in, strain of tuber blotch virus causing, 643.

tuber injury, La. 362.

tubers, inhibition of sprouting, 602.

Up-to-Date variety, top necrosis in, identity, 644.

varieties, Mich. 755.

varieties, combining disease resistance and high yield and good qualities, U.S.D.A. 616.

variety tests, Alaska 617, Ga. 617, Kans. 618, Miss. 325, Nebr. 41, Okla. 755, R.I. 326, Tex. 42.

virus diseases, 343.

virus-free, production in southwest England, 644.

virus X, effect on growth and yield, 210.

virus X, severity of strain mixtures in varieties, 773.

virus Y, transmission by *Aphis rhamni*, 210.

## yield(s)—

and mineral content, effect of minor element compounds, 456.

effect of manure, alfalfa, and pastured sweetclover on, Nebr. 41.

in response to right fertilizers, Ohio 326.

increase by manure and fertilizer, Ohio 326.

Poultry—see also Chick(s), Chicken(s), Duck(s), Fowl(s), Hens, etc.

and egg situation outlook for 1943, Mich. 800.

artificial insemination of, Kans. 666, Minn. 184.

autopsy examinations of, R.I. 384.

blood, hemoglobin in and methods for determination, 685.

body form in, 802.

body measurements and production characteristics, effect of environment v. heredity, 37.

breeding and cross-breeding studies, N.C. 468.

breeding for meat production, Calif. 750.

breeding operations in Canada, mortality during, 248.

breeds possessing high egg production and early feathering tendencies, development of strains, Kans. 612.

cecal worm removal, efficacy of phenothiazine for, 250.

## Poultry—Continued.

colds in, sulfathiazole for, 824.  
 consumer demand in resort areas of western Michigan, Mich. 695.  
 Cornish Bantams, growth, 802.  
 cross-breeding, Kans. 320.  
 crosses between inbred lines, 612.  
 disease(s)—  
   and parasites, U.S.D.A. 98.  
   Ranikhet, vaccination against, method, 249.  
   respiratory, control, 824.  
   studies, Calif. 824, Kans. 676.  
   transmissible, report of committee on, 814.  
 dusting with hypochlorite powders, possible irritating effects, 104.  
 early feathering, sex-linked, modified expressions of, 377.  
 effects of thyroid and gonadotropic preparations in, 321.  
 enterprise on Kansas farms, economics of, Kans. 838.  
 fat, storage changes in, Kans. 666.  
 fattening, methods and rations for, 88.  
 feather picking prevented by fiber, Okla. 797.  
 feeding, economy and efficiency, effects of feed supplements in, R.I. 379.  
 feeds, farm price, 1933-38, Mo. 110.  
 fertility in, seasonal variation, Mo. 84.  
 freezing preservation, N.Y.State 272.  
 frozen, factors affecting quality, 273.  
 gains in weight and increases in fat, covariance analysis for data on, 669.  
 gains of different breeds, Mo. 84.  
 grass silage and modified rations for, Kans. 666.  
 growth, relation to date of hatching, Mo. 84.  
 handling, types of, by cooperative associations, Ohio 394.  
 hatching ability, relation to eggshell texture, Mich. 237.  
 house litter, problem of moisture in, N.H. 235.  
 improvement in southeastern Europe, U.S.D.A. 540.  
 Improvement Plan, National, changes in, U.S.D.A. 669.  
 industry, economics of, Kans. 693.  
 inheritance of lethal condition affecting both mandibles, 376.  
 laying house, time- and labor-saving equipment for, Ohio 235.  
 Leghorn, unselected, and strains bred for resistance to leukosis complex, comparative viability, 377.  
 lice control, U.S.D.A. 98.  
 lice, notes, 502.  
 management manual, 272.  
 mites, U.S.D.A. 98.  
 molasses in feed of, 517.  
 normal growth, Mo. 84.  
 nutrition, new developments in, 514.  
 nutritional experiments, 378.

## Poultry—Continued.

nutritional requirements, Mo. 84.  
 one mash for all ages, Miss. 281.  
 parasites and treatment for removal, U.S.D.A. 676.  
 pH of digestive tract, 803.  
 phenothiazine v. hemoglobin, 250.  
 plant protein feeds for, Pa. 667.  
 production characteristics and body measurements, effect of environment v. heredity, 320.  
 production, profits in, Utah 235.  
 production strains, laying tests for identifying, Okla. 797.  
 products, packing by freezing, U.S.D.A. 723.  
 protein needs of, effect of war, N.Y.State 801.  
 pulse rate, method of measuring, 801.  
 rations—  
   animal protein required in, 800.  
   corn products and silage in, Nebr. 84.  
   fiber and "bulk" in, effect on feather picking and cannibalism, 89.  
   protein, replacement by soybean products, Ark. 797.  
   riboflavin in, 518.  
   varying amounts of vitamin D with high manganese levels in, Tex. 85.  
 reproduction, effect of *Lactobacillus casei* e eluate fraction, 802.  
 research program in Canada, 180.  
 resistance to *Salmonella pullorum*, relation to body temperature, 377.  
 results of hypophysectomy in, 377.  
 Rhode Island Red, breeding for rapid feathering, Mass. 468.  
 Science Association meeting, papers, 376.  
 Single-Comb White Leghorn, improvement of general viability in, 376.  
 sorghums and corn milling byproducts for, Nebr. 84.  
 utilization of fat by, 376.  
 wastes, utilization, U.S.D.A. 723.  
 White Leghorn fed high and low protein rations, egg production and mortality, 377.  
 White Leghorn females, lopping of combs in, 469.  
 White Leghorn males, body weight, effect of different periods of illumination, 377.  
 White Leghorn males, effect of dubbing, 237.  
 White Plymouth Rock strains for specific purposes, 377.  
 Powder-post beetles, studies, N.J. 79.  
 Powdery mildew control by fungicides and resistant varieties, R.I. 344.  
 Power equipment, cost of operating, Oreg. 839.  
 Prairie—  
   ant, mound-building, damage to highways by, 510.

- Prairie**—Continued.  
 grasses, drought resistance of seedlings, 744.  
 hay as source of vitamin A, Okla. 808.  
 hay for dairy cattle, Okla. 808.
- Pratylenchus pratensis***—  
 notes, U.S.D.A. 203.  
 on citrus, 343.
- Precipitation**—see also Rainfall, Snow, etc.  
 centuries-long tree-ring records of, 13.  
 contrasts, average, in United States, 158.  
 maps and regionalization of United States on precipitation basis, 445.
- Precipitinogens**, separation from bacterial spores, 457.
- Predators**, biological control, 652.
- Pregnancy**—  
 prolonged, in lactating rat with oestrogen, experimental control, 40.  
 relation to nutrition, 131.
- Pregnant mare serum**, purification of gonadotropic hormone in, Mo. 34.
- Pressure in tropical regions**, synchronous variations of, 159.
- Price(s)**—  
 control, ancient experience with, 393.  
 control program as it affects the station, Miss. 142.  
 wartime, relation to work of agricultural engineers, 687.
- Pricklypear**, see Cactus.
- Prionus**—  
*californicus*, see California prionus.  
*laticollis* in subterranean wooden duct for telephone cables, 362.
- Pristiphora* spp.**, development after hibernation in cocoon, effect of temperature, 229.
- Production, prices, and income**, index numbers, Ohio 110.
- Profenusa canadensis***, notes, N.Y.State 785.
- Progesterone effect on pituitary lactogen and on mammary glands of ovariectomized rats**, 753.
- Prolactin**—  
 assay, methods for, 91.  
 studies, 725.
- Prospaltella* spp.**, effect of dormant sprays on, 510.
- Protein(s)**—  
 and allied substances, effect of light on, N.Y.State 149.  
 cellular, dissociations by auxins, relation to growth, 27.  
 hydrolyzate, new color test for tryptophan in, 730.  
 hydrolyzates, hydroxylysine in, 587.  
 hydrolyzates, preparation of amino acids from, 581.  
 macromolecules, isolation and crystallization by hydrophilic colloids, 346.  
 molecules, electron micrographs of, 746.  
 nitrogen, determination by Kjeldahl method, effect of nitrates, 587.  
 studies with casein-aldehyde plastics, N.Y.State 149.
- Protein(s)**—Continued.  
 supplements, relative efficiency for ruminants, 513.
- Proteus vulgaris***, production of active and inactive catalase by, 458.
- Protoperce sexta***, see Tobacco hornworm.
- Protoplasmic streaming**, effect of auxins, 312.
- Protostrongylus* spp.** infesting bighorn sheep, Wyo. 245.
- Protozoan parasites**, studies, Kans. 676.
- Provitamin A carotenoids**, assays of, 9.
- Prune**—  
 dwarf, 69.  
 fruit, russet and protuberances on, 357.  
 Italian, pollination, 339.  
 Sugar, blossom bud differentiation, effect of deflorating or defruiting, 339.  
 thrips control, Oreg. 655.  
 worm, destructive in Idaho, Idaho 224.
- Psallus seriatus***, see Cotton flea hopper.
- Pseudananas* genus**, taxonomic study, 25.
- Pseudaphycus utilis***, parasite of coconut mealybug, P.R. 655.
- Pseudocentera mali***, notes, N.Y.State 785.
- Pseudococcus***—  
*sacchari*, experiments with, 658.  
*saccharicola*, life history and bionomics, 658.
- Pseudomonas-Phytomonas* fluorescent bacteria in soil**, activity, 61.
- Pseudomonas putrefaciens***—  
 characteristics, distribution, and taxonomy, 240.  
 in dairy products, 239.
- Pseudorabies**, see Paralysis, infectious bulbar.
- Psila rosae***, see Carrot rust fly.
- Psittacosis***—  
 in chickens cause of human infection, 686.  
 in pigeons and relation to human pneumonitis, 678.  
 studies, U.S.D.A. 98.
- Psittacosislike* infection in domestic and game birds of Michigan**, 251.
- Psocids on milled rice**, U.S.D.A. 73.
- Psylla pyricola***, see Pear psylla.
- Psyllidae**, new, from Puerto Rico, P.R.U. 222.
- Ptinus californicus* in insect nests**, 73.
- Public welfare in Michigan**, reorganization, Mich. 125.
- Puccinia***—  
*allii-phalaridis*, biological study, 647.  
*phyllostadiæ*, new record for India, 204.
- Puerto Rico Federal Station notes**, 288.
- Puerto Rico Station report**, 720.
- Puerto Rico University Station notes**, 429.
- Pullet(s)**—  
 disease, cholera-like, Mich. 248.  
 growth rate, relation to production characteristics and viability, 377.  
 pastures for, 377.  
 respiratory-nervous disorder in, 104.  
 Rhode Island Red, feeding methods and rations, Ohio 516.

## Pullet(s)—Continued.

White Leghorn, calcium and phosphorus requirements, 377.

## Pullorum—

agglutination test, Kans. 676.

disease—see also *Salmonella pullorum*.

antigens, U.S.D.A. 676.

eradication, Mass. 249.

rapid whole blood agglutination test for, 826.

serum agglutination test, drawing blood samples for, Oreg. 825.

Pullorumlike disease in poultry, 240.

Purchasing, local government, savings in, Tex. 111.

Purdue University notes, 427.

Purines, fermentative decomposition by *Clostridium* spp., 583.

Purple scale on citrus, effect of magnesium deficiency on infestations, 77.

Pyrausta nubilalis, see Corn borer, European.

Pyrethrins in fly sprays, activators for, 498.

## Pyrethrum—

and rotenone, relative toxicity to *Ornithodoros moubata*, 664.

substitute, need for, 657.

toxicity, determining, quantitative interaction of spray fluid and active principle, 654.

v. roaches, 221.

Pyridine and nicotinic acid, 732.

## Pyridoxin—

deficiency associated with convulsive syndrome in rats, 559.

deficiency in rats, pathology and histology of, 418.

deficient rats, occurrence of fits in, 558.

effect on appetite and growth of rat, 558.

effect on urinary excretion of new fluorescent substance, 280.

in honey of different localities, 551.

in wheat and wheat products, 557.

increase in germinating seeds, 313.

metabolite physiologically active in natural products, 712.

nutrition of lactic acid bacteria, 458.

paper on, 705.

storage in rat, 859.

## Pyrimidine—

analog of thiamin and growth of fungi, 312.

stimulating yeast fermentation in blood cells and urine of normal humans, measurement and metabolism, 415.

Pyrroline and pyrrolidine derivatives action on firebrat, 365.

## Pyruvate—

dissimilation by pigeon liver accompanied by fixation of carbon dioxide, 583.

metabolism by liver from pantothenic acid- and biotin-deficient rats, 859.

## Pyruvic acid—

in blood and cerebrospinal fluid, variations in, 416.

removal from human blood in vitro, 280.

*Pythiomorpha gonapodyides* growth, relation to pyrimidine analog of thiamin, 313.

## Pythium—

root rot of grasses, 206.

spp. from dead roots of orange and lemon, Calif. 495.

*ultimum* on peas, N.Y.State 66.

*verans* on avocado, Calif. 494.

## Q fever—

epidemiology of, 525.

epidemiology, role of cow in transmission of human infection, 244.

## Quail—

bobwhite, protein requirements for survival, growth, and efficiency of feed utilization, 361.

pairing responses to sex hormone pellet implants, 322.

Study Association, Cooperative, reports, 653.

Quarantine adjustments considering biological findings, 500.

*Quercus* species of Central America, U.S.D.A. 201.

Quince, Japanese, use as food, 296.

Quilnoa anatomy and chemical composition, 315.

*Quinqueserialis quinqueserialis*, life history studies, 230.

## Rabbit(s)—

adequacy of simplified diets for, 549.

attempts to modify sex ratio in, 610.

blood enzyme, atropinesterase, inheritance of, 750.

broad-leaved milkweed poisonous to, 248.

cottontail, body weight and sex ratio, 360.

cottontail, home range, 360.

degenerative disorder of nervous system designated ataxia, 36.

effect of feeding coffee grounds to, 235.

extrauterine pregnancy in, 753.

mammogen and unilateral mammary gland growth in, 470.

New Zealand white, pituitary weight, relation to live weight, 183.

raising, 497.

tick, seasonal history in Oklahoma, 664.

Rabbitbrushes, rubber from, N.Dak. 624.

## Rabies—

diagnosis and prevention, 390.

experimental, treatment of wounds in, 814.

report of committee on, 814.

viruses, plurality in, Venezuela, 390.

## Radish—

*Fusarium* wilt, 355.

induced formation of  $\beta$ -glucoside in, 172.

*Raillietina cesticillus*—

in poultry, nutritional requirements, 249.

studies, Kans. 676.

Rain, heavy summer, effect on soil losses from cultivated land, N.C. 446.

Rainfall—see also Precipitation.

and runoff from watersheds of Missouri, compilation, U.S.D.A. 594.

and runoff in Santa Cruz River drainage basin, Ariz. 445.

**Rainfall—Continued.**

- at State College in 1942, driest year in 54-year record, Miss. 736.
- distribution over surface of unlevel ground, factors governing, 158.
- effect on mineral composition of forage, Okla. 756.
- effect on soil crust formation, Okla. 737.
- evaluation as aid to irrigation interval control, 13.
- heavy, in New Mexico and Arizona, characteristics, 736.
- interception, effect of cutting mature lodgepole pine stands, 639.
- of varying duration, intensity-frequency, 593.
- papers on, 445.
- runoff, and soil loss from Little La Crosse River and Coon Creek Watersheds, U.S.D.A. 736.
- runoff, and soil loss from South Fork Palouse River, U.S.D.A. 736.
- spring, in United States and sunspot period, 593.
- tabulated data, Ga.Coastal Plain 299.

Ramie fiber, present situation in, 286.

*Ramularia* spp., new and interesting from Mt. Shasta, 601.

Rancidity in milk, prevention, 674.

**Range(s)—**

- condition, guides to determine, U.S.D.A. 327.
- conditions, improving for wartime livestock production, U.S.D.A. 620.
- improvement, conservation of flood water for, Mont. 688.
- land, destruction of cacti on, 506.
- lands, Montana, reseeding to increase yield, U.S.D.A. 757.
- livestock industry, problems and policies facing, 536.
- management and burning, U.S.D.A. 665.
- management, effective, appraisal of range survey methods for, U.S.D.A. 326.
- national forest, important plants on, U.S.D.A. 327.
- regrassing for soil protection, U.S.D.A. 756.
- reseeding for increased feed supplies, Utah 187.
- reseeding tests, Utah 620.
- sagebrush-grass, forage improvement on for increased wartime meat production, Colo. 757.
- subalpine grassland, basis for judging, U.S.D.A. 43.

**Raphanus—**

- polyploid forms, self-incompatibility in, 317.
- raphanistrum* as breeding host of green peach aphid, 499.

Rapid plant bug studies, Tex. 73.

**Raspberry (ies)—**

- breeding for South, 627.
- Cuthbert, crown degeneration, Oreg. 641.
- decline disease, 777.
- diseases, control, N.Y.State 203.

**Raspberry (ies)—Continued.**

- fertilizer requirements, N.Y.State 193.
- fruitworm, notes, Mont. 655.
- Milton, new variety, description, N.Y. State 196.
- mosaic, mild forms, effects, 60.
- phosphorus and calcium in, 133.
- production, Mo. 339.
- root-borer, notes, Mont. 655.
- soils of British Columbia, 196.
- variety tests, Ga. 627.

**Rat(s)—see also Rodent(s).**

- androgen production during pregnancy and lactation, 321.
- antigraying factor for, Ohio 409.
- appetite and growth, effect of deficiencies of vitamin B group, 558.
- calcium and fat utilization, interrelation, 132.
- convulsive syndrome in, due to pyridoxin deficiency, 559.
- feeding carotene products to, results, 234.
- female, effect of postnatal androgenic treatment, 39.
- flea, oriental, in Kansas, 510.
- hermaphroditic, anatomy of, 36.
- hypophysectomized, effect of oestrin implants on tibia, 183.
- inbred, vitamin A requirements, relation to genetic factors, Tex. 35.
- intact and castrated female, masculine copulatory behavior in, 614.
- interlitter and intralitter variation in as response to vitamin D, 284.
- lactating, basal energy metabolism, Mo. 92.
- on pantothenic acid-deficient diet, nature of reddish material on nose and whiskers, 284.
- on synthetic diet, effect of substitution of bicarbonate for chloride in, 134.
- oviducts and egg transport in, 752.
- parabiotic, effect of oestradiol on secretion of gonadotropic hormone in, 321.
- parallel embryonic development in and relation to superfetation, 470.
- suckling, selection of nipples by, effect on mammary system, 471.
- Vitamin B<sub>2</sub> complex-deficient, red staining of paws and whiskers in, 566.

**Rationing—**

- bibliography of, U.S.D.A. 111.
- wartime, in Elre, U.S.D.A. 540.

Raven, white-necked, relation to agriculture, 653.

**Rayon—**

- how to sell and care for, 865.
- production in first six months of 1942, 572.
- yarns, plastic-coated, 572.

**Red mite—**

- control, 512.
- European, control, Conn.[New Haven] 499.
- European, control, tank-mixed oil sprays for, N.Y.State 785.

**Red mite—Continued.**

European, early season v. summer control, 363.

**Red scale—****California—**

*Comperiella bifasciata* as parasite, 796.

laboratory fumigations, 366, 789.

protective stupefaction of, 782.

resistant and nonresistant strains to fumigation with HCN, 788.

resistant and nonresistant strains to methyl bromide, comparison of susceptibility, 76.

spray-fumigation experiments, 789.

stupefaction with sublethal dosages of hydrocyanic acid, 76.

toxicity of trichloroacetonitrile to, 72.

control, fumigation in, 659.

difference in two races and relation to tolerance to HCN, 788.

Florida, Tex. 73.

parasites, oriental races in California, comparison, 664.

**Red spider—**

control on lima beans, N.Y.State 785.

control on strawberries, new practice for, La. 362.

on alfalfa in greenhouse, new organic insecticides for, 782.

studies, Ark. 72, Kans. 655.

**Redwood—**

crown gall, 359.

cut-over lands, natural restocking, 201.

Reed canary grass for pasture and hay, seeding practices and seeds, N.J. 187.

Refrigerator, farm milk, dual motion development in, 257.

Reindeer compared with domestic animals as to fattening, sex, and increase, 86.

Relay, simple photoelectric, description, 177.

Rennin, crystalline, preparation, 813.

Reproduction and lactation, effectiveness of linoleic, arachidonic, and linolenic acids in, 859.

Resazurin test, paper on, 520.

Research—see also Agricultural research.

analysis, cross-sectional and case-grouping procedures in, 693.

**Reservoirs—**

evaporation from, 736.

in Trinity River Basin, sedimentation in, relation to land use, Tex. 106.

stratified flow in and use in prevention of silting, U.S.D.A. 532.

**Resins—**

stable, from pine gum, U.S.D.A. 723.

synthetic, from lactic acid, intermediates for, U.S.D.A. 723.

Respiration in virus-infected plants, 769.

**Rhagoletis—**

*cingulata*, see Cherry fruitfly.

*pomonella*, see Apple maggot.

**Rhizobium—**

cultures for inoculating alfalfa in Argentina, 312.

japonicum, persistence in soil, 166.

**Rhizoctonia—**

*mucoroides*, mycorrhizal associate of *Zeusinc stratematica*, 27.

soil-borne, prevalence, effect of environment, 351

solant, notes, 63.

solant on peas, N.Y.State 66.

solant, single basidiospore isolates, cultural differences, 770.

*Rhizopertha dominica*, see Grain borer, lesser.

**Rhizopus—**

pattern, 486.

*suinus*, carbohydrate nutrition of, 31.

Rhode Island College notes, 429.

Rhode Island Station notes, 429.

Rhode Island Station report, 426.

*Rhopalosiphum pseudobrassicac*, see Turnip aphid.

*Rhopalothrips bicolor*, notes, 72.

Rhubarb, ascorbic acid in, 559.

*Ribes alpinum*, formation of adventitious roots, 457.

**Riboflavin—**

and thiamin deficiencies, relation, Ark. 845.

and turkey egg hatchability, Pa. 667.

bibliography supplement, 417.

deficiency in chick, genetic resistance to, 749.

deficiency, succinoxidase system of rat liver in, 856.

effect on appetite and growth of rat, 558.

fate of on baking, 151.

history and properties, 374.

in citrus fruits, 856.

in common foods, 557.

in defatted milk solids, 674.

in foodstuffs, fluorimetric estimation, 591.

in fruits and vegetables, determination, 437.

in honey of different localities, 551.

in poultry rations, 518.

in prepared foods, 281.

in urine and tissues of rats, fluorimetric assay, 710.

in urine, fluorimetric estimation, 591.

in wild rice, 857.

increase in germinating seeds, 313.

metabolism in American cockroach, study by fluorescence microscopy, 658.

microbiological assay for, growth stimulants in, 734.

microbiological method for, 438.

of various products, Mass. 708.

papers on, 705.

pure, use in poultry mashes and concentrates, 804.

relation to cataract formation in rats, 417.

report on, 733.

- Riboflavin**—Continued.  
 requirement of turkeys for hatchability and growth, 376.  
 solutions, effect of light on, 734.
- Ribonuclease**, crystalline, ultraviolet absorption spectrum, 585.
- Rice**—  
 and rice milling products, thiamin in, Ark. 845.  
 blast, varietal resistance, Ark. 769.  
 breeding, Ark. 755, Tex. 42. U.S.D.A. 616.  
 carriers of N and P for, Tex. 42.  
 culture tests, Tex. 42.  
 disease-resistant varieties, U.S.D.A. 616.  
 diseases, Tex. 69.  
 drier, farm-sized, description, Ark. 833.  
 fertilization, Ark. 40.  
 fertilizer tests, Tex. 42.  
 fertilizers, methods of applying, Tex. 42.  
 field mosquitoes, control, Ark. 783.  
 irrigation, water resources for, Ark. 106.  
 leaf spot fungus races and subraces, 642.  
 moth on milled rice, U.S.D.A. 73.  
 physiological studies, Tex. 25.  
 polishings, use in cooking, Lin. 700.  
 prices paid Arkansas farmers, comparisons, Ark. 270.  
 proteins, digestibility and biological and supplemental values, Ark. 845.  
 respiration, fermentation, and growth, effect of oxygen tension, 745.  
 stinkbug as sorghum pest, 783.  
 stored, insect pests, control, U.S.D.A. 73.  
 tolerance to different soil reactions, Tex. 42.  
 transplanted and direct sown, comparative yields, 623.  
 variety tests, Ark. 755, Tex. 42.  
 weevil, mineral oils and tar oils for, 217.  
 weevil studies, U.S.D.A. 73.  
 yield, effect of green manure, Ark. 755.
- Ricinus communis***, development of node in, 465.
- Rickettsia**—  
*conjunctivae* infection, epidemiology of, 528.  
*dermacentrophila* n.sp., description, 242.  
*Rictularia* sp., parasite of squirrel, 497.
- Rinderpest**, transmission experiments by *Tabanus orientis*, 244.
- Rirea corymbosa***, history, nomenclature, and composition, 601.
- River stages**, daily, at gage stations, 299.
- Road burdens and services** in rural towns, N.H. 400.
- Robin**, nesting habits, 654.
- Rocky Mountain spotted fever tick** and tularemia in sheep, 102.
- Rodent(s)**—*see also* Mice and Rat(s).  
 and mosquito control, Conn.[New Haven] 499.  
 biological control, 652.  
 wild, granuloma in lungs of, spontaneous coccidioidal, 391.
- Roentgen rays**, *see* X-ray.
- Root knot**—  
 chemical control, 484.  
 nematode—  
 in high ridge plantings of potatoes and tomatoes, 484.  
 larvae populations in special areas, 484.  
 reaction of commercial cotton varieties to, 484.  
 on plants, effect, Ga.Coastal Plain 344.
- Root nodules**, *see* Nodule bacteria.
- Root parasitism**, anatomical study, technique for, 204.
- Root stimulants**, Tex. 599.
- Roots**, entry of water into, device for measuring, 463.
- Rose(s)**—  
 black spot control in commercial plantings, R.I. 344.  
 bushes, effect of pruning on bloom production, 55.  
 diseases, Tex. 60.  
 effect of soil reaction, Ohio 331.  
 hip sirup, vitamin C in and stability, 862.  
 hips, vitamin C in, 714, Conn.[New Haven] 127.  
 hybrid, understock resistant to nematode, 496.  
 in greenhouse, soil management, Wash. 767.  
 in storage, effects of growth-regulating substances on shoot development, 341.  
 in storage, prevention of shoot development on, 637.  
 plants, storage, Oreg. 628.  
 powdery mildew control in commercial plantings, R.I. 344.  
 powdery mildew control in greenhouse, [N.Y.]Cornell 358.  
 understocks, susceptibility to nematode root knot, U.S.D.A. 58.
- Resin products** to replace scarce ones, U.S.D.A. 723.
- Rotation of crops**—  
 Miss. 326, Mo. 15, Nebr. 41, R.I. 326.  
 on dry land and under irrigation, Mont. 619.
- Rotenone**—  
 analytical isolation from spray solution, 72.  
 and pyrethrum, relative toxicity to *Ornithodoros moubata*, 664.  
 dusts, carriers of, 365.  
 dusts, increased toxicity with, 657.  
 elaboration, effect of nutritional levels on, 463.  
 lower concentrations, 221.  
 producing crops, culture and physiology of, P.R. 629.
- Roughages**, carotene content, reflected in milk, Ohio 380.
- Roundworm parasites** of cattle, U.S.D.A. 98.
- Royal jelly** and bee bread, vitamins in, 82.
- Rubber**—  
 analysis of plants in South Carolina, 31.  
 bacterial oxidation, 309.  
 bacterial oxidation, prevention, 778.

## Rubber—Continued.

from *Castilla*, U.S.D.A. 768.  
from milkweeds and other plants secreting latex, N.Dak. 623.

guayule, production under irrigation, 637.

*Hevea*, cultivation in tropical America, 25.

native plants as possible sources, N.Y. State 767.

plant, Colorado, rubber from, N.Dak. 624.

sources, tests of potential plants as, U.S.D.A. 627.

substitute Norepol, U.S.D.A. 723.

synthetic, from lactic acid, intermediates for, U.S.D.A. 723.

synthetic, intermediates, U.S.D.A. 723.

synthetic, research on, U.S.D.A. 723.

tree (*Hevea*), selection and propagation of high-yielding resistant strains of, U.S.D.A. 627.

tree leaf blight, control by crown bud-ding, U.S.D.A. 341.

Rubidium bromide, absorption and accumulation by barley plants, 173.

*Rubus*—

new dwarf species and Asiatic relatives from China and Tibet, 169.

single-bud stem cuttings, rooting, use of mist spray in, 627.

## Ruminants—

digestibility studies, 232.

rumen gases and bloat in, Oreg. 676.

## Runoff—

and percolation studies of soil types of Illinois, 450.

forecasting in Humboldt Basin, Nevada, 300.

water, velocity, method for determining, 828.

## Rural—

community(ies)—

in transition, Va. 124.

Landaff, N. H., culture of, U.S.D.A. 271.

of Cumberland Co., local leadership in, Tenn. 844.

of New York, effect of status on attitudes in, [N.Y.]Cornell 543.

Old Order Amish of Lancaster Co., Pa., culture of, U.S.D.A. 271.

Sublette, Kans., culture of, U.S.D.A. 406.

credit, *see* Agricultural credit.

cultural conflict and acculturation in southern Brazil, 843.

education in, United States, 543.

Electrification Administration, report, U.S.D.A. 830.

housing in the South, 608.

labor, *see* Farm labor.

life, changes in, effect of the war, 697.

life, satisfaction in, attempt to measure, 697.

living, changes in, survey, U.S.D.A. 718.

## Rural—Continued.

population in Tennessee, nutrition of, 132.

population, social well-being of, factors affecting, Kans. 697.

youth group of Randolph Co., Ill. 542.

youth of Ross Co. level of living and social achievement, Ohio 698.

*Rumula* sp., unusual development of fruit bodies, 27.

Rust mite on pears, control, Oreg. 655.

Rusts, parasitization in Kansas, U.S.D.A. 58.

Rusts, tropical American, revisionary studies, 612.

Rutabagas, vitamin B deficiency in, R.I. 326.

## Rye—

cold resistance, factors affecting, Nebr. 41.

culture tests, Mont. 619.

haploid, meiotic mechanism of, 35.

milling products, vitamin E in and effect of bleaching, 715.

variety tests, Ga. Coastal Plain 325.

Ryegrass, new cover for vineyards, N.Y. State 186.

Saccharic acids, identification as benzimidazole derivatives, 725.

*Saccharomyces* on dates, 358.

## Safflower

culture tests, Tex. 42.

irrigation tests, Tex. 42.

production tests, Kans. 618, Tex. 42.

variety tests, Nebr. 41.

*Sagaritis pronancheri*, parasite of tobacco budworm, 783.

Sage, propagation by cuttings, 631.

*Saintpaulia ionantha* ring spot, cause, 649.

*Saissetia*—

*hemisphaerica*, *see* Hemispherical scale.

*oleae*, *see* Black scale.

Salicylates, fungicidal value, 346.

Salicylic acid from naphthalene by bacterial oxidation, Pa. 583.

## Salmon—

canned, bacteriological survey, 700.

canned, production of staphylococcus enterotoxin in, 409.

cheek quality as affected by freezing and storage, Oreg. 579.

*Salmonella*—

*donaricensis* suggested name for new *Salmonella* type, 248.

*choleraesuis* in swine, nicotine acid for prevention, 108.

*choleraesuis* var. *kunzendorf*, somatic antigens of, 528.

control in foods, 408.

cultures, serological identification, Ky. 817.

genus, coliform bacilli serologically related to, 388.

infections in pigs, 529.

organisms, serological type determination, 678.

**Salmonella**—Continued.

pullorum—see also Pullorum disease.

resistance of chicks to, effect of X-ray treatments, 531.

species, evolution and description of unusual type, 526.

spp. in intestines of chickens, isolation and pathogenicity, 387.

spp. in turkey poults, 105.

types, new, with related specific antigens, 251.

**San Jose scale**—

control on apple, effect of summer sprays, N.Y.State 785.

parasites, effect of dormant sprays on, 510.

**Sand**—

areas, blowing, stabilization, adaptability of native plants for, Tex. 25.

dunes, coastal, in Pacific Northwest, control, U.S.D.A. 450.

hill areas, range studies in, Nebr. 42.

Sandbags, prolonging life of, U.S.D.A. 688.

**Sanninivora**—*cattiosa*, see Peachtree borer.*opalescens*, see Peach borer, western.**Sarcophaga miasa** as transmitter of *Endamoeba histolytica*, 370.**Sarcophagidae**, Hawaiian, 227.**Sarcoptes scabiei**, see Itch mite.**Sardines**, canned, quality, volatile fatty acidity as index, 150.**Sauerkraut**—

acceptable for Government purchase, production, 295.

dehydration, 545.

dried, made into bricks freed from air in new packaging process, N.Y.State 850.

factories, heating, when, how, and why, 295.

**Sausage-casing material**, Visking, action on bacterial growth, 291.**Sawfly**—

infestations in Pennsylvania, 604.

wheat stem, notes, Mont. 655.

**Scabies**—see also Mange.

eradication, U.S.D.A. 076.

parasitology, quantitative aspects, 654.

transmission and development, 654.

**Scale insect(s)**—see also Black scale, Purple scale, and Red scale.

armored, status of friendly fungus parasites, 223.

control by predators, P.R. 655.

dormant sprays for, Miss. 479.

on coffee in Puerto Rico, relation to ants and other organisms, P.R.U. 223.

on ponderosa and Jeffrey pines, seasonal history, 224.

**Schaefferia** to *Smilax*, host-parasite checklist revision, U.S.D.A. 58.**Schizosaccharomyces pombe** dead cells, absorption of neutral red by, as index of toxicity of bacterial antibiotic substance, 600.**Schizura conchina**, see Caterpillar, red-humped.**School(s)**—

high, students of classes of 1934-41, occupational roles 6 months after graduation, Wash. 542.

lunch for improving diets of high school students, 547.

milk program of Agricultural Marketing Administration, U.S.D.A. 128.

**Science**, contribution to food preparation, 272.**Scirphophaga rhodoproctalis**, natural enemy of, 793.**Scirtothrips citri**, see Citrus thrips.**Sclerospora macrospora**, cause of oat downy mildew, 348.**Sclerotinia sativa** on alfalfa and sweetclover, varietal resistance to, 349.**Sclerotium**—*bataicola* on sorghum, Tex. 60.*rhizodes* on grasses, U.S.D.A. 58.*rolfsii*, interaction with thiamin, 602.*rolfsii*, notes, Tex. 60.**Scobicia declivis**, see Lead-cable borer.**Scolytus**—*multistriatus*, see Elm bark beetle, smaller European.**Scours**, treatment, sulfaguanidine in, Pa. 676.**Screwworm**—

and blowfly problem, U.S.D.A. 97.

fly, newly introduced pest, Mont. 652.

infestation, factors predisposing animals to, 794.

larvae, ants as predators, 795.

larvae development in carcasses, 817.

secondary, as transmitter of *Endamoeba histolytica*, 370.

secondary, seasonal distribution, 81.

**Scurvy** in guinea pigs, activity of alkaline serum phosphatase, 569.**Seaweeds** at Beaufort, N. C., as source of agar, 174.**Sediment** transported by aqueous and atmospheric density currents, kind and quantity, 449.**Seed(s)**—

activities of grain inspection laboratory with, Mont. 619.

certification a national asset, 484.

certification, opportunities in, 484.

dormant, mitotic disturbances induced in, relation to X-ray dosage, 35.

germinating, increase of B vitamins in, 313.

germination, effect of seed-borne microorganisms on, 484.

germination, inhibition of, 174.

germination studies, 46.

inspection, Ky. 330, Vt. 330.

inspection and testing, N.Y.State 762.

official samples, merits and characteristics, N.Y.State 190.

stocks of 1942, N.Y.State 186.

tests, N.H. 476.

**Seed(s)**—Continued.

## treatment—

and war needs, N.Y.State 771.

tests in laboratory and field, N.Y.  
State 203.with synthetic growth substances,  
Ohio 46.weed, *see* Weed seeds.

Seedbed preparation studies, Tex. 42.

Seed-corn maggot, notes, Mont. 655.

Seedlings from X-rayed seeds, auxin and  
calines in, 743.**Selection**—

artificial, progress with, 469.

experiment, new extreme variants in,  
749.on family basis, results to be expected  
from, 610.**Selenium**—absorption by corn from *Astragalus* ex-  
tracts and solutions containing pro-  
teins, 173.compounds, chemistry and toxicity and  
problem in agriculture, 579.content of vegetation and mapping of  
seleniferous soils, 454.indicator species of *Astragalus*, identifi-  
cation, 31.soluble, in soils and availability to  
plants, 308.

toxicity, factors affecting, 527.

*Selenothrips rubrocinctus*, *see* Thrips, red-  
banded.**Semen**—smears, preparation, effect on abnormal  
types of spermatozon, 184.

stallion and jack, dilutors for, 614.

storing, packaging, and shipping, 90.

swine, rabbit, and poultry, collection and  
storage, Mo. 34.

Semimicronitrometer, du Pont type, 730.

**Septicemia**—

hemorrhagic, U.S.D.A. 97.

paratyphoid, in horses, 529.

**Septoria**—

leaf spot on celtuce, U.S.D.A. 640.

*tycopernica* on tomatoes, control, 648. spp., new and interesting from Mt.  
Shasta, 601.*Septosperma rhizophidii* n.g. and n.sp., de-  
scription, 486.**Sericea**—

as silage and hay crop, 185.

correct time of cutting for good hay,  
N.C. 473.

effect on soil fertility, 185.

in crop rotations, 184.

seeding rate, 185.

**Serine**—dietary, effect on liver lipids of rats,  
703.in proteins, liability toward alkali and  
its consequences, 582.

Sesame production tests, Kans. 618.

Sewage sludges, chemical composition, N.J.  
738.Sex of progeny, genetic constitution of mother  
as means of predetermining, 749.Sex, predetermination in *Drosophila melano-*  
*gaster*, 612.

Shad oil, vitamins A and D potency, 706.

Shark-liver oil—

and vitamin A potency of milk, 673, 807.

effect on milk and butterfat production,  
809.

vitamin D in 798.

Sheep—*see also* Ewe(s) and Lamb(s).and cattle, rotation on pasture as aid  
in parasite control, Ohio 383.and goats, crosses between, cytological  
studies, Tex. 35.artificial insemination with fresh and  
stored semen, 324.black disease in, vaccination against,  
Mont. 670.

breeding, Mont. 666.

breeding for Georgia conditions, Ga. 611.

breeding, management, and judging, 230.

clean fleece weight estimation from un-  
scoured fleece weight and staple  
length, 513.

cobalt deficiency in South Australia, 389.

cobalt deficiency symptoms in, efficacy  
of cobaltized salt for prevention, 389.cross breeding and reproduction studies,  
U.S.D.A. 800.cross-breeding for lamb and wool produc-  
tion, Wyo. 181.Deccan, breeding, wool quality as basis  
of individual selection in, 611.

diseases and parasites, U.S.D.A. 98.

diseases, control, Kans. 389.

effect of stilboestrol on sperm produc-  
tion, 615.enzootic ataxia and copper deficiency,  
389.

fattening on alfalfa, 375.

fertility in, hormonal augmentation of,  
616.fertility in, seminal changes in rams  
affecting, 615.fine wool, selection for polled character  
in, Tex. 35.fineness of wool and mohair, relation to  
age, Tex. 85.

fleece worm infestations, treatment, 820.

foot rot in, Mont. 678.

gastrointestinal parasites, best control  
for, Ohio 383.

grazing logged-off land with, Oreg. 666.

grazing methods on bromegrass-alfalfa  
pastures, Nebr. 42.grazing on *Phalaris tuberosa*, staggers  
syndrome in, 528.

grazing preferences, Nebr. 42.

herds of the station, N.Dak. 373.

hybrid vigor in, 318.

livers, hard yellow, Tex. 99.

Merino, blowfly strike of breech, relation  
to tail length, 217.Merino, of Australia, "density" and re-  
lated characters of fleece, 799.

## Sheep—Continued.

nematode larvae, differentiation, preparation and examination of fecal cultures for, 217.

nematodes in pasture, survival, 389.  
on bitterweed ranges, maintenance, Tex. 85.

parasites and treatment for removal, U.S.D.A. 676.

parasites, control, Ga. 682.

parasitic worms of, control, 389.

permanent marking and tattooing, U.S. D.A. 665.

## Rambouillet—

and Romney, and crosses between, inheritance of fiber characteristics, Tex. 35.

clean wool yield variation among regions of fleece, 513.

fiber density of fleeces, 513.

inheritance of skin folds on, Tex. 35.

range, blood phosphorus, U.S.D.A. 665.

range methods for, Mont. 666.

range, phenothiazine medicated pellets for, 103.

range, weanling and yearling fleece characters, relation, 233.

rations for wintering, Alaska, 666.

stomach, nodular, and tapeworms in, comparative damage, Mo. 99.

stomach worm, heavy infections, fatalities from, 381.

strivey wool indicative of copper deficiency, 86.

urinary calculi in, 389.

vitamin A and carotene requirements, 798.

vitamin A requirements, Tex. 85.

wheat as feed for, Utah, 667.

worm burden, on improved and unimproved hill pastures, 821.

Sheets, four classes, service study, 423.

Shellfish, analyses, Me. 545.

## Shelterbelt—

plants at North Platte Substation, effects of November freeze, Nebr. 47.

seedlings, transplanting methods to increase survival, Mont. 628.

*Shigella* infections, ants as probable agents in spread, 371.

## Shrubs—

effects of November 1940 freeze, Kans. 628.

for shelterbelt uses, tests, Mont. 628.

native, identification and landscape uses, Miss. 342.

propagation, Mo. 47, Okla. 763.

propagation by seed, Okla. 194.

## Silage(s)—

alfalfa, U.S.D.A. 670.

bluegrass-molasses, alfalfa-molasses, and corn, digestible nutrients in, 514.

corn, and grain rations, U.S.D.A. 670.

corn, vitamin A and carotene values, U.S.D.A. 670.

costs of, Mo. 110.

## Silage(s)—Continued.

grass, evaluation as succulent feed, 519.

grass, for West Virginia, W.Va. 473.

grass, preservation studies, Pa. 671.

laboratory, electrode potentials in, 374.  
of various kinds, use for feeder calves, Ark. 707.

small grain-legume mixture, N.C. 520.

soybean feeding to helpers, N.C. 473.

Silica in soil extracts, determination, 150.

Silks, effect of sodium thiosulfate and sodium hydrogen sulfite on, 286.

Silos, moisture drainage from, methods, 535.

Silver sprays, composition and field performance, 345.

Silviculture, American, and silvics, 638.

Sinusitis, infectious, in turkeys, Oreg. 676.

Sires—see also Bull(s).

Holstein-Friesian, proved, dam-daughter comparison of daughters, 610.

in serve on dairy herds at N. D. A. C., N.Dak. 720.

Sisal plantings in Haiti, Cuba, and Mexico, U.S.D.A. 617.

*Sitona cylindricollis*, notes, Mont. 655.

*Sitophilus oryza*, see Rice weevil.

*Sitotroga cerealella*, see Angoumois grain moth.

## Skim milk—

acid-precipitated casein from, methods for manufacturing, U.S.D.A. 96.

in swine rations, Ark. 83.

odor produced by *Pseudomonas putrefaciens* in, 239.

*Skrjabinema parva*, notes, 384.

*Skrjabinoptera*—

genus, present knowledge and world host list and key, 654.

*phrynosoma*, redescription, 654.

Slime control, materials recommended for, relative toxicity, 154.

Snail, brown, control in citrus orchards, 72.

## Snakes—

of United States and Canada, field book, 217.

venomous, Central American records and snakebite accidents, 218.

## Snapdragon(s)—

cytological studies, N.Y.State 193.

diploid, colchicine induced univalents in, 467.

new pest of, 362.

tetraploids, sterile intra- and fertile intervarietal, comparative cytology, 609.

tetraploidy induced by sanguinarine hydrochloride, 180.

## Snow—

and ice, papers on, 445.

Conference, Central, papers, 14.

cover and stream flow in Colorado, correlation, 299.

melt, prediction of stream flow from, 445.

perennial, and glaciers, 736.

sampling tubes, tests, 300.

**Snow**—Continued.

- storage and melting, effect of openings in young lodgepole pine forest, 343.
- survey, Mont. 688.
- survey tubes and accessories, canvas case for carrying, 300.
- surveys and irrigation water forecasts—
  - for Colorado River Drainage Basin, Colo. 736, U.S.D.A. 736.
  - for Missouri and Arkansas Drainage Basins, Colo. 736, U.S.D.A. 736.
  - for Oregon, Oreg. 736, U.S.D.A. 736.
  - for Rio Grande Drainage Basin, Colo. 736, U.S.D.A. 736.
- surveys, Nevada cooperative, 300.

**Soaps and other water-softeners, selection by homemakers, 718.****Social organization, rural and rural sociology, 540.****Social problems, studies by station, N.C. 541.****Sodium**—

- determination in presence of phosphates, 586.
- fluorescein as fertilizer, Tex. 599.
- fluoride, toxicity for cockroaches, 365.
- hydroxide, germicidal properties, evaluation, 243.
- thiosulfate, stabilization, 290.

**Soil(s)**—

- acidity, effect of potash and magnesia losses, N.C. 446.
- active manganese in determination, 452.
- alkaline-calcareous, plant food availability in, Ariz. 20.
- alluvial, of Mississippi drainage basin, properties, U.S.D.A. 162.
- and fertilizer studies, U.S.D.A. 594.
- and plant research, Federal-State cooperation in, 15.
- and root system, electrochemical relations, 447.
- and their use by men, 446.
- and water conservation, relation to grassland farming, 107.
- and water conservation studies, Tex. 15.
- and water losses under different conditions, N.Y.State 160.
- and water losses under different cropping methods, Ark. 15.
- bacteria, flagella staining technic for, 310.
- bacteria, pigments produced by, N.Y. State 159.
- bacterial activity, effect of soil treatments long continued, Mo. 15.
- base exchange capacity determination, 18.
- building, use of cornstalks and straw in, Mo. 15.
- carbon content under burning and non-burning, 185.
- classification, soil acidity relations as aid, N.C. 446.
- clay and colloid content determination, 6.
- colloids, *see* Colloids.

**Soil(s)**—Continued.

- colors, standardization, Ohio 301.
- composition, relation to plant and animal deficiencies, Tex. 21.
- conservation—
  - cover crops for, U.S.D.A. 186.
  - in West Virginia, economics of, W.Va. 395.
  - studies, N.Y.State 160.
- crop-producing capacity, maximum, Mont. 619.
- crust, cultivation for, Okla. 737.
- density, water content, and porosity relations, rapid calculation, nomograms for, 447.
- dry, thermal conductivity, 303.
- erosion—
  - control, Nebr. 15.
  - control, crop rotation as factor, 164.
  - control, effect of periodic close grazing and pasture fertilization, 596.
  - control practices for wartime needs, 688.
  - control, value of ground cover for, N.C. 446.
  - effect of irrigation water, Utah 595.
  - effect on fertility changes in Shelby loam profile, 164.
  - experiment station at Guthrie, Okla., work of, U.S.D.A. 737.
  - measurements and control experiments, revision, U.S.D.A. 164.
  - studies, Mo. 15.
  - variability of material eroded, 18.
  - wind, effect on composition and fertility of Alberta soils, 304.
  - wind, relation to types of vegetative cover, 453.
- extracts, silica and phosphoric acid in, 150.
- fertility—
  - and improvement studies, Tex. 42.
  - and maintenance, Miss. 300.
  - and soil tests, Colo. 738.
  - indices of, comparison, with peanuts, 185.
  - leguminous plant material incorporated with soil v. leguminous mulches for, 185.
  - level, effect on plant nutrient composition and consumption, Ind. 737.
  - studies, Kans. 595. Oreg. 595.
- field capacity and permanent wilting percentage in, jacketed thermal radiators as indicators, 302.
- for crop production, Miss. 159.
- forest, changes in microflora and composition of decomposing leaves, 185.
- free iron oxides in, removal, 164.
- freezing and forest cover, 452.
- from which old peach trees were removed, disinfection, N.C. 476.
- fumigation for control of crop pests, Tex. 60.
- greenhouse and field, chloropicrin for sterilizing, Ohio 331.

## Soil(s)—Continued.

- heavy or alkaline, drainage and improvement, Oreg. 595.
- introductory course at Michigan State College, evaluation, 543.
- Laterite, and related soils of Thailand, analyses and profile, 163.
- management and crops for war production, Mich. 737.
- management, best systems for important soil types, Mo. 15.
- moisture—
  - conservation, Nebr. 15.
  - content indicator, electrical capacity of 2-electrode plaster of paris block as, 162.
  - content indicators, 2- and 4-electrode plaster of paris blocks as, 161.
  - continuous measurement by electrical resistance, absorbent materials for, 16.
  - determination, comparison of methods, 17.
  - measurement, new method, Ohio 300.
  - phenomena in frozen soils, 737.
  - potential, 595.
  - storage, utilization, and evaporation, Kans. 595.
  - variations, response of electrical resistance of 2- and 4-electrode plaster of paris blocks to, 448.
- movement by tillage implements, 829.
- Muskingum, water relations and erosion U.S.D.A. 17.
- nitrogen content, *see* Nitrification and Nitrogen.
- nutrients, chloropicrin as factor in mobilization of, 738.
- of Alabama in lysimeters, nitrogen losses from, 166.
- of Corn Belt States, effect of depth of topsoil and organic matter and nitrogen in, N.Y.State 160.
- of Georgia, available potash and phosphate in, Ga. 594.
- of Hawaii, boron in, 24.
- of Idaho, phosphate deficiency determination by *Azotobacter* plaque test, 166.
- of Illinois, runoff, percolate, and leaching losses from, 450.
- of Mexico, textbook, 159.
- of Miami family and Miami catena, morphology and composition, U.S.D.A. 163.
- of New Jersey, pH values and lime requirements, N.J. 739.
- organic, and soil mixtures, structure shown by pH moisture studies, 161.
- organic matter in, *see* Organic matter.
- pasteurizer, continuous, 109.
- phosphate fixation in, control, 167.
- physical constitution of water-stable granules and of originating soil, 160.
- Piedmont, properties of B horizons, 302.

## Soil(s)—Continued.

- productivity in profitable agriculture, 185.
- productivity, maintenance, Mont. 596.
- profile(s)—
  - mounts, preparing, method and demonstration, 595.
  - organic carbon distribution, 150.
  - studies, Nebr. 15.
- protection in Southwest, regrassing for, U.S.D.A. 756.
- reaction as basis for land management, practices, 19.
- receiving excess gypsum, calcium- and sulfate-ion concentrations in, 24.
- solution, relation to pH and other factors, Kans. 595.
- southern, organic matter in and available nutrients, effect of leguminous plant additions, 455.
- sterilization with chloropicrin and relation to effect of preceding crop, R.I. 301.
- sterilization with urea and calcium cyanamide, 484.
- sterilizer, inexpensive, description, 165.
- structure—
  - important item in soil fertility, Pa. 595.
  - microscopic method of study, 301.
  - nature and effect on tillage, Mo. 15.
- studies, application of polarograph in, 5.
- survey data, uses in regional development program, 185.
- survey in—
  - California, Pixley area, U.S.D.A. 595.
  - California, Wasco area, U.S.D.A. 302.
  - Iowa, Iowa 15.
  - New York, Albany and Schoenady Cos., U.S.D.A. 16.
  - New York, Seneca Co., U.S.D.A. 302.
  - North Carolina, Madison Co., U.S.D.A. 302.
  - North Carolina, Warren Co. U.S.D.A., 160.
  - Oklahoma, Tulsa Co., U.S.D.A. 302.
  - Rhode Island, Newport and Bristol Cos., U.S.D.A. 160.
  - Tennessee, Roane Co., U.S.D.A. 302.
  - Utah-Arizona, Virgin River Valley area, U.S.D.A. 595.
- surveys, importance in wartime adjustments, U.S.D.A. 594.
- synthetic, as bacteriological culture medium, N.Y.State 159.
- systems, dry cohesive, mechanism of water attack on, 450.
- testing as basis for fertilizer recommendations, 185.
- type pattern of Monkato drift plain in Iowa, effect of low recessional moraines, 302.
- types of Missouri, determination and mapping, Mo. 15.

**Soll(s)**—Continued.

volume-freezing-point relations observed with new dilatometer technic, 447.

water, *see* Soll moisture.

Yazoo River, fertilizer elements needed in, Miss. 598.

*Solanum* sp. from Chile, susceptibility to *Fusarium solani cumartii*, 352.

*Solenopsis geminata*, *see* Fire ant.

*Solubea pugnax* on sorghum, 783.

*Solutoparies pythii* n.g. and n.sp., description, 486.

*Sophora* to *Sorbus*, host-parasite check-list revision, U.S.D.A. 58.

Soremouth of sheep and goats, Tex. 99.

**Sorghum(s)**—

and corn and effects on succeeding crops, comparisons, Tex. 42.

and Johnson grass hybrid, F<sub>2</sub> and F<sub>3</sub> generations of, 185.

breeding, Kans. 618, Nebr. 41, Okla. 755, Tex. 42, U.S.D.A. 616.

breeding for low cyanide content, 185.

charcoal disease, Tex. 60.

charcoal rot, Nebr. 59.

crosses for waxy endosperm grain, Kans. 618.

deficiencies as feed for dairy cows, Kans. 671.

disease resistance in, breeding for, Kans. 640.

diseases, control, 210.

double cropping experiments, Tex. 42.

for Kansas, Kans. 329.

grain—

combined, curing in trenches, Tex. 42.

culture tests, Kans. 618, Tex. 42.

disease resistance in, Tex. 60.

fertilizer tests, Tex. 42.

harvesting and storing methods, Kans. 688.

irrigation tests, Tex. 42.

new, saving harvest labor and resistant to chinch bugs, U.S.D.A. 616.

variety-spacing test, Tex. 42.

variety tests, Ga.Coastal Plain 325, Kans. 618, Nebr. 41, Okla. 755, Tex. 42.

grains, industrial utilization, Kans. 579.

heat, light, and drought tolerance in, Kans. 618.

inheritance studies, Tex. 42.

kernel smut control, new fungicides and reduced dosages for, 490.

plant characters induced by radiation, inheritance of, 608.

planting tests, Nebr. 41.

response to fallow and other tillage practices, Nebr. 41.

sirup, homemade, W.Va. 441.

sirup, utilization, Ga. 579.

smuts, pathogenicity and genetics, Minn. 489.

starches from, U.S.D.A. 723.

value for feed and food, Ark. 40.

**Sorghum(s)**—Continued.

waxy starches (replacing tapioca) from, U.S.D.A. 617.

**Sorgo**—

breeding, Kans. 618, Tex. 42, U.S.D.A. 616.

byproducts from, U.S.D.A. 723.

Leoti, for starch, Nebr. 475.

planting for production of high-proof alcohol for explosives, U.S.D.A. 617.

sirup as source of alcohol, U.S.D.A. 723.

variety tests, Ga.Coastal Plain 325, Kans. 618, Nebr. 41, Okla. 755, Tex. 42.

Sowbugs control, 501.

Sows—*see also* Pigs) and Swine.

brood—

effect of manganese in rations, Mo. 84.

ground alfalfa for, Mich. 668.

performance, effect of diet, 514.

individuality in regard to size of litter, 612.

litter size and weight as permanent characteristics, U.S.D.A. 318.

management and breeding, Ga.Coastal Plain 373.

Soxhlet extractor, improved, 290.

**Soybean(s)**—

Arkan. Magnolia, Boone, and Gibson varieties, U.S.D.A. 616.

Biloxi, microsporogenesis in, effect of photoperiod, 465.

breeding, Ark. 755, Mo. 41, Nebr. 41, U.S.D.A. 616.

culture tests, Kans. 618, Miss. 186, Tex. 42.

diseases, U.S.D.A. 58, 343, 640.

edible, food crop for Hawaii, 624.

edible, undetermined virus disease, U.S.D.A. 58.

edible, variety tests, Tex. 42.

effect of day length on, U.S.D.A. 607.

effect of hormone treatments, Miss. 618.

emergency storage for, Mo. 835.

fast-drying oil from, U.S.D.A. 723.

feeding to pigs, 514, 797.

fertility needs and cultural practices for, Mich. 755.

fertilizer tests, Kans. 618.

fiber development by Ford, 865.

flour, kinds, as pollen substitutes, 83.

frogeye leaf spot, new records for, U.S.D.A. 58.

Gibson and Patoka, adaptations, characteristics, and yields, Ind. 476.

hogged down, minerals with, N.C. 514.

hogging off, Ga.Coastal Plain 373.

infection with *Rhizobium japonicum*, effect on fodder yield and quality, 773.

meal as feed for lambs, Kans. 666.

meal in poultry feed, 378.

meal in rations for fattening cattle, laxative nature, 513.

meal, plastics from, U.S.D.A. 723.

meal with pilchard fish meal or meat meal, combinations, gross values, 236.

## Soybean(s)—Continued.

- new crop for Puerto Rico, culture, P.R.U. 476.  
 nodule bacteria strains associated with different host varieties, N fixation by, 176.  
 nutrients in, effect of soil fertility, Ind. 737.  
*Peronospora* on, U.S.D.A. 203.  
 planting tests, Ga. 617.  
 plants, amount of boron absorbed by and effect on growth, 645.  
 production, adaptation on cotton farms for oil mills, Ark. 755.  
 production in Kansas, Kans. 330.  
 protein as source of amino acids for chick, 801.  
 respiration and storage behavior, Minn. 431.  
 root knot resistance, varietal, 484.  
 root knot studies, Ga. 617.  
 Seminoles, increase of seed, P.R. 619.  
 studies, W.Va. 473.  
 varieties, Mich. 755.  
 varieties, earlier, tests, Ohio 326.  
 varieties for seed, N.C. 473.  
 varieties, relative adaptations among, physiological causes, Mo. 25.  
 variety tests, Ark. 755, Ga. 617  
 Ga.Coastal Plain 325, Kans. 618, Miss. 186, 325, Mo. 41, Nebr. 41, Pa. 619, Tex. 42.  
 war crop for Delta farmers, U.S.D.A. 45.  
 with and without preservatives for milk production, U.S.D.A. 670.  
*Spartium* to *Syringia*, host-parasite check-list revision, U.S.D.A. 202.  
 Specimens, embedding in methacrylate resins, U.S.D.A. 5.  
 Spectrograph, inexpensive, for analysis of plant ashes, 190.  
 Spermatogenesis—  
   in hypophysectomized rats following injection of gonadotropins, effect of testosterone propionate, 472.  
   in rats, 751.  
 Spermatozoa—  
   bovine epididymal, metabolism, 323.  
   bull, cytochrome oxidase in, 728.  
   bull, nonhemin and total iron in, 727.  
   survival in female reproductive tract of bat, 324.  
*Sphacelotheca sorghi*, pathogenicity and genetics, Minn. 489.  
*Sphaerotheca lanestris* on live oak, 780.  
 Sphagnum—  
   use for growing seedlings, U.S.D.A. 627.  
   use to control damping off, N.J. 646.  
 Spice—  
   contamination control, 291.  
   crops, culture, P.R. 628.  
 Spider—  
   beetle, California, in insect nests, 73.  
   fauna of Puerto Rico, additions to, P.R.U. 83.  
   mite, *see* Red spider.

*Spilonota ocellana*, *see* Budmoth, eye-spotted.

## Spinach—

- dehydration tests, 849.  
 leaf proteins, isolated, release of auxin from, 213.  
 leaves, chloroplast substance of, 404.  
 seed-borne micro-organisms, N.Y.State 203.  
 seed treatment, Miss. 354, Tex. 59.  
 soil calcium and oxalate content, 604.  
 thiamin determination in, 438.  
 wilt caused by *Fusarium* sp., N.J. 491.  
 Spleen in male rats, effect of thyroidectomy, castration, and replacement therapy, 755.  
*Sporocytophaga myzococcoides*, notes, 305.  
*Sporodinia* pattern, 486.  
*Sporotrichum malorum* and *Phialophora malorum*, relation, 492.  
 Spotted fever in Gulf coast of Texas, 388.  
 Spray(s)—*see also* Fungicide(s), Insecticide(s), and specific forms.  
   concentrated, experiments, 782.  
   copper, *see* Copper.  
   injury, correctives for reducing, Mo. 47.  
   mixture, inverted, use of term, 783.  
   oil, *see* Oil sprays.  
   rigs, use for fire-extinguishing purposes, Mich. 692.  
   tests, Pa. 652.  
   winter, season for, Miss. 786.

## Spruce—

- Alaskan airplane, importance of fungi and defects in handling, 780.  
 and fir stands, effect of cutting on volume, 638.  
 beetle, eastern, estimation of forest damage by, 219.  
 budworm, notes, Mont. 655.  
 defoliators identification, frass key for, 502.  
 Norway, planting stocks, tests, N.Y.State 200.  
 sawfly, European—  
   biological control in New Hampshire, 511.  
   control, 372.  
   diapause and egg intoxication in, 511.  
   distribution in Scandinavian and eastern Baltic countries, 511.  
   natural control by small mammals, 664.

Spurge, caper, proteolytic enzyme in latex of, 29.

Squab raising, U.S.D.A. 370.

Square root transformation and analysis of variance, use with contagious distributions, 361.

## Squash—

- blister beetle, biology, 227.  
 borer control, Conn.[New Haven] 499.  
 breeding, N.Y.State 191.  
 bug control, Mo. 72.  
 bug, effect of sulfonated oils combined with cube and derris, 787.

**Squash—Continued.**

- bug studies, Tex. 73.
- culture, Mont. 628.
- disease-resistant and improved varieties, development, N.Y.State 191.
- plants, growth in water culture, effect of micro-organisms, 67.
- summer, loss of vitamin C during cooking, 862.
- yields, relation to insect control, Ohio 362.

**Squirrel(s)—**

- fox and gray, animal parasites of, 497.
- gray, habitat distribution of, 300.

**Stablefly—**

- breeding in shore deposits of bay grasses, control, 371.
- control, 654.
- false, parasitic habits, 662.
- studies, U.S.D.A. 98.
- waste celery as important breeding place, control in, 509.

**Stachytarpheta virus diseases, 779.****Staggers syndrome in sheep and cattle grazing on *Phalaris tuberosa*, 528.****Stain(s)—**

- biological, N.Y.State 149.
- removal from fabrics, home methods, U.S.D.A. 286.

**standardization, progress in, 607.****Staining rack for handling cover-glass preparations, 317.****Stallion enrollment, Ind. 800.****Standard of living, empirical test of definition, 844.****Standards, biological, reports on, 183.****Staphylococcal toxins, studies, 242.****Staphylococci control in foods, 408.*****Staphylococcus aureus*, cause of loss of turkey poults, 105.****Starch(es)—**

- evaluating for textile purposes, 8.
- reserve, effects of growth substances, 461.
- solutions, stabilization, 290.
- structure and mechanism of formation, 456.

**Starlings—**

- and foot-and-mouth disease, 387.
- oogenesis in, 38.

**Starter solutions, use of, N.Y.State 191.****Steers—see also Cattle, beef.**

- alfalfa-molasses silage for, Pa. 666.
- blood plasma ascorbic acid of, effect of gonadotropic substance of pregnant mare serum, 38.
- fattening—
  - cottonseed meal v. peanut meal for, Tex. 85.
  - oats for, Okla. 797.
  - on ground hegarl fodder v. ground redtop fodder, Tex. 85.
  - rations, maintenance and growth requirements, 797.
  - velvetbeans, cottonseed meal, and peanut meal as protein feeds for, U.S.D.A. 85.

**Steers—Continued.**

- feeding, comparisons of rations, Ga. Coastal Plain 872.
- feeding program, use of pasture in, Mich. 667.
- sweetpotato pulp for, U.S.D.A. 665.
- wintering on crested wheatgrass, Mont. 667.
- yearling, finishing, cottonseed meal as supplement to reeds for, N.C. 514.
- yearling, protein supplements, comparison, 513.

***Stegasta bosqueella* on peanut and partridge pea, Ga. 654.*****Stegobium paniceum*, see Drug store weevil.*****Stemphylium* gray spot of tomatoes, Tex. 59.*****Stephanoderes flos*, studies, Tex. 73.****Sterilization and cleaning studies, N.Y.State 149.*****Sternocochus paludatus*, life history, habits, and control in New Mexico, U.S.D.A. 505.****Stinkbug—**

- Say, notes, Mont. 655.
- Say, on cotton, control by dusts, 504.
- southern green, Tex. 73.

**Stock, see Livestock.****Stock foods, see Feeding stuffs.****Stockyards fever, see Septicemia, hemorrhagic.****Stomach worms—**

- in range sheep, phenothiazine-medicated pellets for, 103.
- in sheep and goats, Tex. 99.
- in sheep, relation to diet, 682.

***Stomoxys calcitrans*, see Stablefly.****Storages, air-cooled, effect of ice on temperatures in, 190.****Stoves, pressure gasoline and pressure kerosene, Nebr. 287.****Strangles, vaccination against, 530.****Straw left by combine, baling methods, 833.****Straw, use in soil building, Mo. 15.****Strawberry(ies)—**

- beds, renovation, N.C. 476.
- Blakemore, yields, effect of renewal systems and width of row, 53.
- breeding for South, 627.
- culture, Ark. 763.
- diseases, Idaho 493, Oreg. 641.
- Dunlap, effect of naphthaleneacetic acid in promoting parthenocarp in, Nebr., 47.
- effects of mulching, Ark. 762.
- fertilizer requirements, N.Y.State 193.
- fertilizers for, N.C. 340.
- fertilizing, time factor in, N.C. 476.
- flower development and structure, effect of fertilization and pruning, Ark. 40.
- insects, control, Ark. 783, Mo. 72.
- leaf blotch in Great Britain, 777.
- leaf roller, biology and control, Kans. 655.
- mites, dusting for control, N.C. 500.
- mulching, Kans. 628.
- nitrogen requirements, Ark. 762.
- nutrition in upper South, 627.
- nutritive requirements, N.C. 476.
- plant behavior, effect of mulch, 53.

**Strawberry(ies)—Continued.**

- plant, effect of high temperature, Okla. 763.
- plants, inoculation with *Phytomonas fasciens*, 215.
- preservation with sulfurous acid, Ga. 700.
- red stele root rot, serious new disease, Mich. 777.
- sawdust mulch for, Ga. 627.
- sun-ripened v. shade-ripened, vitamin C in, N.C. 476.
- Tennessee Beauty, new variety, Tenn. 635.
- value of stable manure for, Ark. 763.
- varieties, plant-spacing experiments, 53.
- variety tests, Ga. 627.
- vitamin C determination in, variations in samples, 713.
- weevil, toxicity of insecticides to, laboratory tests, 361.
- yield and grade, effect of renovation of beds after harvest, 481.
- yields, effect of fertilizers, Ga. 627.
- trem flow—
  - and snow cover in Colorado, correlation, 299.
  - effect of wall-friction on gravity-waves, 392.
- Streptococci—**
  - active resting cells, production, 458.
  - equine, studies, 529.
  - hemolytic, from horses treated with sulfanilamide, 390.
- Streptococcus—**
  - agalactiae—*
    - dehydrogenation of alcohols by, 600.
    - housefly as vector, 101.
    - pathogenicity for mice and treatment with sulfanilamide, 678.
  - equi*, cross-immunity to, 530.
  - equi*, experimental immunity to, 529.
- Strip cropping for war production, U.S.D.A. 737.
- Strongyloides—**
  - papillorum*, percentage incidence in cattle, 101.
  - ransomi* in heart tissue of pigs, death due to, 384.
- Stubble mulch culture, relation to machinery developments in, 185.
- Stumpage and log prices for 1939 and 1940, U.S.D.A. 58.
- Subulina octona*, injury to vanilla plantings, P.R. 656.
- Succinoxidase system—
  - effect of calcium salts on, mechanism, 853.
  - of rat livers in riboflavin deficiency, 856.
- Succinylsulfathiazole in veterinary practice, 677.
- Sudan grass—**
  - as supplement to native grass for pasture, Kans. 618.
  - breeding, Tex. 42.
  - hybrids, disease resistance in, Tex. 60.

**Sudan grass—Continued.**

- increasing yield of dry matter, nitrogen, and vitamin C, 624.
- Sugar(s)—see also Glucose, Lactose, etc.**
  - and coffee tablets for the Army, U.S.D.A. 723.
  - and its substitutes, Conn.[New Haven] 127.
  - determination, Lane-Eynon method, modification, 590.
  - dextrose and sucrose, effect on ice cream properties, 382.
  - in ice cream, 240.
  - in plants, effect of cations (K, Na, Ca) on conversion, 604.
  - more from domestic sources, U.S.D.A. 723.
  - rationing objectives and allotments, 393.
  - receipts and distribution in United States, 1934-39, U.S.D.A. 695.
  - substitutes and their uses, Mont. 545.
- Sugar beet(s)—**
  - breeding, U.S.D.A. 616.
  - diseases, Nebr. 59.
  - diseases, control, Mont. 641.
  - distribution of mineral elements in, effect of preceding crops, 624.
  - effect of day length on, U.S.D.A. 607.
  - fertilizer tests, Mont. 619.
  - growing, labor-saving devices, Colo. 761.
  - grown for seed, irrigation, U.S.D.A. 45.
  - growth, effect of soil structure, 16.
  - improved leaf spot resistant, U.S.D.A. 617.
  - irrigation tests, Tex. 42.
  - labor needs for, Mich. 755.
  - leaf blight, control, Ohio 344.
  - leafhopper, *see* Beet leafhopper.
  - photosynthesis and respiration in, 746.
  - research, Utah 619.
  - seed growing profitable in certain areas by new production methods, Utah 619.
  - seed, important farm crop, Utah 619.
  - seed, new segmented, for labor saving, Utah 620.
  - seed production, Oreg. 619.
  - seed treatments with plant hormones, 624.
  - seed yields, effect of spacings, U.S.D.A. 617.
  - sucrose in, effect of soil and cultural practices, 761.
  - variety tests, Tex. 42.
  - wireworm adults, flight of, 78.
  - workers, migratory, in Michigan, Mich. 271.
  - yields, effect of manure, alfalfa, and pastured sweetclover on, Nebr. 41.
  - yields, limiting, by lack of air in soils, Ohio 326.
- Sugarcane—**
  - borer—
    - biological control, 508.
    - control, 654, La. 362.

- Sugarcane**—Continued.  
 borer—continued.  
   fly parasite of, receipt of shipments, liberations, and shipment to Cuba, P.R. 655.  
   losses caused by, La. 362.  
   resistant varieties, development and use, 508.  
   studies, 225.  
   breeding, U.S.D.A. 616.  
   byproducts from, U.S.D.A. 723.  
   chlorotic streak, experiments with, 205.  
   disease testing and seedling selection at Houma Station, 210.  
   disease-tolerant, U.S.D.A. 617.  
   diseases, "foreign" and those present in Hawaii, 352.  
   effects of colchicine on anatomy and histology, 317.  
   first application of nitrogen, 625.  
   frog hopper studies, 222.  
   growth rates, 625.  
   in India, new pest of, 658.  
   juice, limed, calcium phosphate precipitate in, 593.  
   juice quality affected by lodging, 45.  
   nutrient deficiencies in, methods of determining, 603.  
   research at agricultural experiment station of University of Puerto Rico, 625.  
   rootstock weevil in sweet corn, Kans. 655.  
   shocked, and silage with carpet grass as roughage for beef herd, Fla. 232.  
   smut studies, 773.  
   stem galls induced with insect extracts, 502.  
   variety tests, Miss. 325, P.R. 619.  
   white moth borer, natural enemy of, 793.  
   yields, effect of hot water treatment of seed cane, 211.
- Suits, men's**, mending, U.S.D.A. 867.
- Sulfaguanidine**—  
   chemotherapy in enteric conditions of swine, 529.  
   effect on rat growth and plasma prothrombin, 854.  
   in veterinary medicine, 677.
- Sulfanilamide compounds**, action on lethal factor of bacterial toxins, 677.
- Sulfasuxidine succinylsulfathiazole** in veterinary practice, 677.
- Sulfathiazole**—  
   and methyl derivative, antibacterial activity, 243.  
   for colds in chickens, 824.  
   use in prevention and treatment of infectious coryza, 686.
- Sulfonamides**, therapy in practice, 677.
- Sunflower(s)**—  
   growth and development, effect of boron, 774.  
   hogging off, Ga. Coastal Plain 373.  
   leaves, *Alternaria* on, in India, 211.  
   seeds, sulfur in and seed weight in relation to effects of sulfur deficiency, 172.
- Sunlight lamps** for laying hens, Nebr. 379.
- Sunshine**, fall and winter, antirachitic effectiveness, 566.
- Sunspot data**, 593.
- Sunspot period and spring rainfall** in United States, 593.
- Superphosphate(s)**—  
   chemical properties before and after ammoniation, 456.  
   effective utilization, effect of preliminary, 598.  
   sludge-acid, plant culture and nitrification studies with, 167.
- Swamp fever**, see Anemia, equine infectious.
- Swamps**, forested, drainage, 639.
- Swans of North America**, life history, 653.
- Sweat**, thiamin in, 137.
- Sweet corn**—see also Corn.  
   bacterial wilt, scarcity of, U.S.D.A. 58.  
   breeding, N.Y. State 191.  
   culture and strain tests, N.Y. State 191.  
   ear rot, U.S.D.A. 343.  
   earworm control in, 660.  
   heat and drought tolerance, effect of tillers, 48.  
   *Helminthosporium* blight, N.J. 490.  
   hybrid tests, N.J. 490.  
   hybrids, increase of quality of table corn by, N.C. 473.  
   kernels, auxin in, relation to endosperm type, 28.  
   market, protecting from European corn borer, U.S.D.A. 226.  
   new, Cherokee, breeding, Ga. 627.  
   pollen, sugar content and aphid susceptibility, 48.  
   varieties for Montana, Mont. 628.  
   variety tests, Miss. 191.  
   yield and quality, effect of irrigation water, 477.
- Sweet pea**—  
   powdery mildew control by fungicides and resistant varieties, R.I. 314.  
   seed and root rots, treatments for, R.I. 344.
- Sweetclover**—  
   biennial, response to moisture, temperature, and day length, 761.  
   biennial white, inheritance of growth habit, cotyledon color, and cup-leaf in, 748.  
   biennial white, inheritance of seed color in, 718.  
   breeding, Nebr. 41, Tex. 42, U.S.D.A. 616.  
   coumarin determination with, Nebr. 41.  
   culture tests, Okla. 756, Tex. 42.  
   cutting and palatability tests, Nebr. 41.  
   disease, hemorrhagic, studies, 817.  
   efficiency of phosphate fertilizers on calcareous soil for, 758.  
   fertilizer tests, Kans. 618.  
   for green manure, Utah 186.  
   pasturing with sheep, Nebr. 41.  
   root- and crown-rotting fungi in Alberta, varietal resistance, 349.

## Sweetclover—Continued.

- rotations, need for plenty of K, Ohio 326.
- superior varieties or strains grown by station, Oreg. 619.
- variety tests, Alaska 617, Kans. 618, Nebr. 41, Tex. 42.
- weevil, newly introduced pest, Mont. 652.
- weevil, notes, Mont. 655.

## Sweetpotato(es)—

- and vine storage in pit silos, Ga. 666.
- bedding roots, nematode control in, Okla. 769.
- breeding, Miss. 186, Okla. 755, Tex. 42.
- care in handling and storage necessary, Miss. 325.
- carotene in, 185.
- carotene in, effect of storage and of breeding, 855.
- culture tests, Miss. 186, N.J. 189.
- curing and storage, 185.
- curing and storage, use of electricity in, 186.
- diseases, prevention, 623.
- drying by natural means, cost and rate, 185.
- fertilizer tests, Ga. 617, Ga.Coastal Plain 325, Miss. 186, N.J. 189, Tex. 42.
- flowering in, factors affecting, 186.
- Fusarium* wilt on tobacco, N.C. 473.
- hogging off, Ga.Coastal Plain 373.
- improving profits on, 622.
- internal break-down due to exposure to cold, La. 352.
- meal and milk-producing ration for cows, 807.
- meal and peanuts on vine as milk-producing feed for dairy cattle, Ga. 671.
- N and K top dressings for, Ga.Coastal Plain 325.
- plant and livestock feed, Miss. 85.
- plant, complete usage, program for determining, 185.
- planting, spacing, and curing tests, Ga. 617.
- processing for livestock feed, machinery for, 258.
- pulp for steers, U.S.D.A. 665.
- ratios of organic:nonorganic N with, Ga.Coastal Plain 325.
- roots, disinfection, Miss. 203.
- secondary nutrient elements for, Ga. Coastal Plain 325.
- starch and carotene from, U.S.D.A. 723.
- storage experiments, Okla. 756.
- storage, spacing, and slip production, Miss. 186.
- studies, Tex. 42.
- varieties for starch production and market purposes, cooperative tests, U.S.D.A. 189.
- vines and tubers for feed, U.S.D.A. 723.
- weevil, biology and seasonal history, La. 362.

## Sweetpotato(es)—Continued.

- weevil, reaction under different qualities of light, La. 362.
- weevil, toxicity of poison baits to, La. 362.

Swine—*see also* Pig(s) and Sows.

- closed herds, selection for growth rate and productivity in, 610.
- disease, transmissible, report of committee on, 814.
- enteritis, nicotinic acid for prevention, 103.
- erysipelas, Nebr. 103, Oreg. 676, U.S.D.A. 676.
- erysipelas antiserum, Nebr. 99.
- erysipelas infection in man, Nebr. 242.
- fever, crystal violet vaccine for prevention, 246.
- herds of the station, N.Dak. 373.
- influenza, studies, 814, U.S.D.A. 98.
- influenza virus, swine lungworm as reservoir and intermediate host, 822.
- influenza virus, synergistic action on chick embryo, 824.
- with inherited bleeding disease, abnormal capillary resistance in, 684.
- with inherited bleeding disease, anomaly of normal Duke's and very prolonged saline bleeding time, 529.

## Symphyliids, studies, Oreg. 655.

Symptomatic anthrax, *see* Blackleg.*Systema blanda*, *see* Flea beetle, pale-striped.*Tabanus orientis*, feeding habits and transmission of rinderpest experiments, 244.*Tabebuia* to *Thespesia*, host-parasite checklist revision, U.S.D.A. 202.

## Tachinidae, new North American, 227.

*Taenia pisiformis*, cysts of squirrel, 497.*Taeniothrips*—

- inconsequens*, *see* Pear thrips.
- simpler*, *see* *Gladiolus* thrips.

*Talitrus sylvaticus*, household pest in California, 362.

## Tamarisk canker in Argentina, 359.

## Tangerines, puffy, in packing house process, cause and prevention, 198.

## Tannages, chrome-saving, U.S.D.A. 723.

## Tanning materials, domestic, developing, U.S.D.A. 723.

## Tapeworms of cattle, U.S.D.A. 98.

## Tarnished plant bug on alfalfa, effect of sulfur with other materials, 782.

*Tarsonemus bakeri*, recently discovered on citrus, 230.

## Tarweed seed in grain as poultry feed, 685.

## Tax(es)—

- assessments, inequalities of, and delinquencies in San Saba Co., Tex. 111.
- burden, property, of Tennessee farmers, Tenn. 841.
- delinquent farm, rate of payment, N.C. 587.
- income, estimation of revenue and incidence, Iowa 120.

**Tax(es)**—Continued.

- rates on farin real estate, recent changes in, N.C. 538.
- trend in representative counties, Tex. 111.

Taxation, farm, in Nevada, Nev. 538.

**Taxonomy**—

- and phylogeny, 460.
- insect, significance of economic entomology in, 499.
- relation to biological control, 499.

**Teeth**—

- decay, effect of nutritional supervision on, 412.
- decay of children and topically applied fluorine, 567.
- decay of children, effect of massive doses of vitamin D, 509.
- decay of rats, induced, effect of fluorides and iodoacetic acid, 568.
- decay, role of nutrition in, 566.
- effect of low calcium and vitamin D-deficient diet of mature rats, 567.
- of dog, fluorine acquired by, 569.

*Teleonemia nigrina*, new pest of snapdragon and verberna, 362.

**Temperature(s)**—see also Climate(s).

- air, annual march, effect of Great Lakes on, 12.
- contrasts in the United States, 12.

*Tephrosia* extract against houseflies, 658.

**Termite(s)**—

- ants, and plants, ecological relations, 311.
- dry-wood or powder-post, control, P.R. 656.
- exposure test, international, 787.
- subterranean, preventing damage to buildings, and control, U.S.D.A. 658.

<sup>6</sup> Terrace construction by plowing, 253.

Terrapin scale parasites, effect of dormant sprays on, 510.

**Testes**—

- deer, oestrogens in, 752.
- of opossum, response to androgenic treatments, 39.

Testosterone, colorimetric reaction for, 590

Tetrachloro-*p*-benzoquinone as growth stimulant, U.S.D.A. 58.

*Tetranychus tritici*, covering stubble for control, Okla. 783.

*Tetranychus*, see Red spider.

**Tetraploidy**—

- in snapdragon induced by sanguinarine hydrochloride, 180.
- in tomatoes induced by colchicine, 179.
- induced, hereditary transmission and compatibility in fertilization, 181.

*Tetrastichus belypti*, effect of dormant sprays on, 511.

**Tettigidea parvipennis**—

- genetics of, 612.
- inheritance of, Kans. 655.

Texas Station report, 142.

**Textile(s)**—see also Fabric(s).

- and synthetic fibers, Kans. 140.
- flexural fatigue of, 573.
- materials, A. S. T. M. standards on, 716.
- resilience of, determination, 285.
- sanitization of, 573.

*Theobaldia inornata*, biology in captive colony, 793.

*Thermobia domestica*, see Firebrat.

**Thiamin**—see also Vitamin B<sub>1</sub>.

- and fungi, interaction, 602.
- and riboflavin deficiencies, relation, Ark. 845.

chemical determination, 592.

**deficiency**—

- and thiamin requirement of man, 138, 710.
- in pigs and methods of assay, 684.
- in rats, mechanism of bradycardia in, 818.

determination, modified microfermentation method, 592.

effect on appetite and growth of rat, 558 in average American diet, 414.

in blood cells and urine of humans, measurement and metabolism, 415.

in citrus fruits, 586.

in common American trees, 313.

in defatted milk solids, 674.

in honey of different localities, 550.

in milk, free and combined, 137.

in milk of various kinds, 414.

in peas, effect of sodium bicarbonate, 858.

in prepared foods, 281.

in rice and rice milling products, Ark. 845.

in sweat, 137.

in vegetables, determination, 438.

in white flour, 436.

in white flour milled by stone milling process, 857.

in wild rice, 857.

intake, and relation to other dietary constituents in food, 553.

normal requirement and factors affecting utilization and excretion, 554.

production by *Actinomyces viridochromogenus*, 458.

retention in self-rising flour biscuits, 557.

**urinary excretion**—

as index of nutritional level, 138.

in children, 710.

in patients with chronic hepatic disease, 553.

*Thielaviopsis basicola*, cause of root rot of cotton, 62.

**Thiobacillus thiooxidans**—

metabolism in absence of oxidizable sulfur, 740.

study with electron microscope, 459.

"Thiosan," new turf fungicide, 206.

Thistle, Canada, control, Oreg. 619.

Threonine in proteins, lability toward alkali and its consequences, 582.

- Thrips**—  
 new, on tuberose bulbs, 222.  
 on roses, Tex. 73.  
 red-banded, parasite of, rearing and liberation, P.R. 656.
- Thrips tabaci*, see Onion thrips.
- Thuja* to *Tsuga*, host-parasite check-list revision, U.S.D.A. 343.
- Thymus in male rats, effect of thyroidectomy, castration, and replacement therapy, 753.
- Thyroid**—  
 desiccated, effect on mammary growth in male mice, 321.  
 extracts, effects on poultry, 321.  
 guinea and chick, comparison in assay of thyrotropic hormone, Mo. 34.  
 relation to growth, 321.
- Thyrolactin, effect on milk production, metabolism, and growth, 91.
- Thyronectria austro-americana* disease of honey locust, U.S.D.A. 58.
- Thyroprotein, highly active, chemical formation, 91.
- Thyroxin, in vitro formation by thyroid tissue, 726.
- Thysanus pulchra*, effect of dormant sprays on, 511.
- Tick(s)**—  
 affecting dogs, U.S.D.A. 98.  
 Canadian, laboratory rearing, 500.  
 collected on Tama (Iowa) Indian Reservation, 230.  
 control, 372.  
 eradication studies, U.S.D.A. 676.  
 fever of cattle, U.S.D.A. 98.  
 fowl, new vector of anaplasmosis, 826.  
 Gulf Coast, relation to screwworm infestation in livestock, Tex. 99.  
 lethal temperatures for, in British Columbia, 372.  
 lone star, as vector of spotted fever in Texas, 388.  
 new species on shrews, 230.  
 Rocky Mountain wood, microbial flora of, 512.
- Tillage operations, movement of soil during, 820.
- Tilletia**—  
*levis* crosses, inheritance of reaction to race 8, 609.  
*tritici*—see also host plants.  
 and *T. levis* hybrids, extent of pathogenicity, 608.
- Timber**—see also Lumber and Wood.  
 marketing studies, Ark. 768.  
 saw, survey in Clearfield County, Pa. 638.  
 stand improvement, Miss. 842.
- Time interval, determining, slide rule for, 478.**
- Timothy**—  
 development, effect of soil temperature, 43.  
 for pasture and hay, seeding practices and seeds, N.J. 187.
- Timothy**—Continued.  
 hay, value as sheep feed in response to soil treatment, Mo. 15.  
 hays, vitamin A and carotene values, U.S.D.A. 670.  
 meadows, superiority on fertile soil, Ohio, 301, 326.  
 nutrients in, effect of soil fertility, Ind. 737.  
 yield and feeding value, effect of fertilizers, Mo. 41.
- Tin**, absorption and excretion by man, 279.
- Tineola bisselliella*, see Clothes moth, webbing.
- Tiphia shaastensis* n.sp., 371.
- Toad(s)**—  
 and frogs of United States and Canada, handbook, 654.  
 giant, feeding habits, 217.  
 in Oklahoma, food of, 498.
- Tobacco**—  
 American, types, use and markets, U.S.D.A. 403.  
 attacked by sweetpotato *Fusarium* wilt, N.C. 473.  
 bacterial wilt, resistance to, 645.  
 black shank, new introduction into Kentucky, U.S.D.A. 202.  
 breeding for black root rot resistance, 484.  
 budworm, mixing poisoned bait for, 498.  
 budworm, parasite of, 783.  
 cigar-leaf, sources of K for fertilizers, Pa. 619.  
 cigar wrapper, studies, Ga.Coastal Plain 325.  
 crops improved after natural weed fallow, U.S.D.A. 617.  
 culture experiments, Ga.Coastal Plain 325.  
 culture practices and root knot control in plant beds and field, Ga.Coastal Plain 344.  
 diseases in Maryland, U.S.D.A. 640.  
 diseases in Virginia, U.S.D.A. 343.  
 downy mildew control by new spray, 352.  
 downy mildew, new fungicide for, U.S.D.A. 640.  
 downy mildew, organism causing, 774.  
 etch virus, measurement of strain, 490.  
 fertilizer placement for, Ga.Coastal Plain 325.  
 fertilizer tests, Ga.Coastal Plain 325.  
 flue-cured—  
 diseases, Ga.Coastal Plain 344.  
 new varieties, introduction, N.C. 473.  
 nutrient absorption by, time and rate, 625.  
 recommendations on, Ga.Coastal Plain 325.  
 variations in prices, N.C. 400.  
*Fusarium* wilt, increase in following sweetpotato, U.S.D.A. 640.  
 hornworm, nature of "cobalt" recommended for control, 490.

## Tobacco—Continued.

- leaf spot bacteria, association with roots of crop plants, 211.
- leaves, effect of water extraction on acyl derivatives of mosaic virus protein, 646.
- leaves, water-soaked, entrance of non-motile bacteria and chemicals, 437.
- magnesium absorption by, effect of source, 456.
- mosaic disease control by breeding, 354.
- mosaic disease, phytopathological classics, 211.
- mosaic virus—
  - biologically active, formation, 65.
  - concentration and purification, 353.
  - containing radioactive phosphorus, preparation and use, 354.
  - effect of cyanide on synthesis of, 646.
  - effect on protein content of susceptible and resistant strains, 353.
  - nucleic acid of, molecular size and shape, 352.
  - protein, amino acids of, fractionation, 353.
  - protein, viscosimetric studies, 646.
  - spread in tomato fields, U.S.D.A. 640.
  - strain causing necrosis and shriveling of tomato foliage, 356.
  - strains, comparison of alkaline cleavage products, 353.
- nicotine and nicotinic acid from, U.S. D.A. 723.
- nicotine in, determination, modification of Official method, 590.
- nicotine production from, U.S.D.A. 45.
- of Southern States, demand for, trends in, Ky. 842.
- on extremely acid soils, poorer root growth of, N.C. 473.
- plant beds, need for less fertilizer on, N.C. 473.
- plant beds, weeds and disease control in, N.C. 473.
- quality and yield, gains in, N.C. 473.
- ring spot on edible soybeans, U.S.D.A. 58.
- ring spot virus, effect of cyanide on synthesis of, 646.
- root diseases, rotations as control factors in, N.C. 473.
- root knot, increase in, following sweet-potato, U.S.D.A. 640.
- roots, excised, nicotine synthesis in, 744.
- rotations, Ga.Coastal Plain 325.
- rows, grade of, effect on drainage and erosion control, N.C. 446.
- secondary nutrient elements for, Ga. Coastal Plain 325.
- shade, diseases, Ga.Coastal Plain 344.
- stocks, plants grafted on, nicotine formation in, 174.

## Tobacco—Continued.

- thrips on shade-grown tobacco, control, 503.
  - warehouses, costs of operating, N.C. 537.
  - yields, high, in manured and fertilized rotations, Ohio 326.
- Tocopherol—
- and stability of carotene, 855.
  - dl  $\alpha$ . in serum, photoelectric determination, 592.
- Tomato(es)—
- anthracnose, new spray for control, N.Y.State 776.
  - ascorbic acid in, effect of mineral nutrition, 560.
  - bacterial canker, control, 355.
  - Bay State, bred for resistance to leaf mold, Mass. 49.
  - blossom-end rot and fruitfulness, macro-element nutrition, 213.
  - blossom-end rot, varietal resistance to, Tex. 59.
  - breeding, Nebr. 47.
  - breeding for resistance to nematodes and diseases, Ga. 627.
  - breeding, use of X-rays in, N.Y.State 191.
  - bushy stunt virus, new crystalline forms, 647.
  - canned, wartime marketing problems of, Ark. 841.
  - canning, diseases and control, N.Y.State 203.
  - catsup as source of vitamin C. 862.
  - collar rot resistance, 355.
  - culture, Mont. 628.
  - culture tests, Ga.Coastal Plain 331, Miss. 191.
  - cuttings, effect of growth substances on starch reserve in, 461.
  - defoliating diseases, anthracnose, and shoestring disease, weather effects, N.J. 490.
  - defoliating diseases, fungicidal control, Ark. 769.
  - direct seeding v. transplanting, Ohio 331.
  - disease(s)—
    - conspectus for, 491.
    - control, Utah, 647.
    - in New York, U.S.D.A. 58
    - resistant, development, Ark. 59.
    - studies, Tex. 59.
  - early blight—
    - breeding for resistance to, Tex. 59.
    - prevention, Miss. 203.
    - spread and development, Ga.Coastal Plain 344.
    - studies, U.S.D.A. 58.
    - susceptibility increased by wilt infection, Miss. 354.
  - Early Chatham, merits, Mich. 765.
  - effect of platinum chloride, 402.
  - effect on urinary acidity and blood alkali reserve, 277.
  - excised root systems, water uptake by, due to nonosmotic forces, 464.

## Tomato(es)—Continued.

- fertilizer requirements, N.Y.State 191.
- fertilizer tests, Ga.Coastal Plain 381.
- fertilizer treatment, plant tissue tests as guide, Ky. 765.
- field plot technic studies with, 477.
- food value, relation to soil fertility, Ohio 381.
- fruit production, effect of chloropicrin—
  - roll-treatment and fungicides, R.I. 344.
- fruit rot, U.S.D.A. 58.
- fruit rot control, varietal resistance and mulching for, Colo. 776.
- fruitfulness in, chemicals to stimulate, 334.
- fruitworm control, 226, 508.
- fruitworm on beans, Tex. 73.
- fruitworm studies, Ohio 362.
- Fusarium* wilt immunity, white flowers as index, Tex. 59.
- Fusarium* wilt resistance, breeding for, Mo. 59.
- grafted on *Datura stramonium*, interaction between, 175.
- Granville bacterial wilt, susceptibility to, N.C. 485.
- gray-wall studies, 478.
- greenhouse—
  - affected by tobacco mosaic virus strain, 356.
  - experiments, Okla. 193.
  - fertilizers for, Ohio 331.
  - nutrient requirements, Ohio 331.
  - production, new research phases in, 334.
  - single-virus streak disease, U.S.D.A. 843.
- green-wrapped, shoulder bruising in, 334.
- hereditary variegation in, 609.
- insects, control, Tenn. 784.
- juice, ascorbic acid in, effect of processing, Ark. 485.
- juice, *Bacillus thermoacidurans* in, detection, 292.
- leaf mold fungus, new strain, 356, Ohio 344.
- leaf spots, control, Ohio 344.
- leaf spots destructive in Ohio, U.S.D.A. 58.
- leaves, fresh weight and area, correlation, 478.
- Marglobe, yields, effect of Cu sprays, Tex. 59.
- natural crossing in, related to distance and direction, 765.
- nematode resistance test, 765.
- nutritive value, conservation of, Utah 720.
- nutritive value, factors affecting, U.S. D.A. 544.
- parthenocarp in, induced by  $\beta$ -naphthoxyacetic acid, 49.
- Pennheart, tests, Pa. 628.
- plants—
  - ascorbic acid content and growth, effect of potassium iodide, 193.

## Tomato(es)—Continued.

- plants—continued.
  - burning, improved fertilizer drill for prevention, Tex. 60.
  - composition in sand culture, effect of concentrations of added salts, 478.
  - growing on the farm, Mich. 764.
  - healthy, production for northern shipment, U.S.D.A. 627.
  - shipping and bacterial wilt, Ga. Coastal Plain 344.
  - tetraploid, induced by colchicine, 179.
  - young, effect of topping on fruit set and yield, 631.
- plowing under coarse organic matter for, effect, 478.
- production, value of starter solutions in, Pa. 628.
- products, canned, keeping qualities, effect of sulfur residue, 782.
- psyllid, notes, Mont. 655.
- psyllid treatment, avoid residue in, 658.
- resistance to bacterial canker, breeding for, 213.
- resistant to defoliation diseases, breeding for, U.S.D.A. 67.
- ring-spot type of virus disease, 491.
- root knot in greenhouses, "precleanup" control for, R.I. 844.
- roots, excised, gall formation by, 68.
- roots, excised, synthesis of ascorbic acid in, 29.
- roots, isolated, reversible growth inhibition, 28.
- russet mite status, 781.
- seed, first-generation hybrid, production, 49.
- seedless, use of indolebutyric acid in production, Ohio 331.
- seedlings transplanted from sand, control of damping-off, Pa. 647.
- septoriose, control, 648.
- single-virus streak in greenhouse, U.S.D.A. 58.
- spoilage from heat-resistant micro-organisms, 776.
- spotted wilt control, 491.
- spotted wilt, spraying tests with tartar emetic, 776.
- staking and pruning, Ark. 762.
- starter solution experiments, 476.
- stored, weight loss and rot in, effect of nutrient root media on, 478.
- tip blight, Oreg. 641.
- transplants, flea beetle injury to, reduction of, 782.
- treatise, 334.
- varieties for greenhouse culture, development, Ohio 331.
- varieties for Montana, Mont. 628.
- varieties, nematode reactions of, Tex. 59.
- variety tests, Miss. 191, N.Y.State 191.

## Tomato(es)—Continued.

- virus tip blight, negative report on, U.S.D.A. 58.
- wheel injury during spraying and dusting, 479.
- whole, home canning, use of calcium chloride in, N.Y.State 129.
- wilt, relation to soil fertility, Miss. 354.
- wilt resistance in, Miss. 208.
- wilt, toxin in, 776.
- yield and quality, effect of irrigation water, 477.

## Tonka-beans, culture, P.R. 628.

## Torrey, John, biography as story of North American botany, 460.

*Torulopsis dactylifera* n.sp., description, 358.

## Towels and toweling for consumer use, Mo. 573.

## Towns, rural, merchandise availability in, 536.

## Toxemia in sheep, Mo. 99.

## Tractor(s)—

- engine, crankcase dilution and fuel economy, effect of jacket water temperature, 832.
- farm, fuel consumed and work performed, U.S.D.A. 392.
- farm, type, size, age, and life, U.S.D.A. 108.
- fuel waste by operator of, Pa. 688.
- level for laying out contour lines, 689.

## Trade—

- agreement, reciprocal, United States-Peruvian, U.S.D.A. 124.
- foreign, of Mozambique, U.S.D.A. 405.

*Tradescantia*—

- chromosomes, X-ray effects on, N.Y.State 193.
- cytological studies, N.Y.State 193.
- microspores, five-day, chromosomal effects of low X-ray doses on, 746.

*Trametes* spp. attacking spruce in Great Lakes region, 216.

## Transpiration—

- and evaporation, report of committee on, 445.
- rhythmic fluctuations in, under constant environment, 170.

## Transportation—

- congressional mandate on, Hoch-Smith Resolution, U.S.D.A. 402.
- efficient, now a necessity, N.Dak. 394.

## Tree(s)—

- American, thiamin in, 313.
- coniferous, see Conifer(s).
- effects of November 1940 freeze, Kans. 628.
- for shelterbelt uses, tests, Mont. 628.
- forest, diseases, resistant strains for control, U.S.D.A. 640.
- forest, photosynthesis in, Vt. 483.
- forest, propagation, Mo. 47.
- fruits, new varieties, testing, Kans. 628.
- hardwood—

- British, principal decays of, 781.
- chemical control of sprouts, 57.

## Tree(s)—Continued.

## hardwood—continued.

- early responses to weeding in, 483.
- stand improvement, relation to diseases in, U.S.D.A. 650.
- injury during November blizzard, relation to hardy rootstocks, Nebr. 47.
- leaves, decomposing, composition, 165.
- mixed hardwood, improvement cuttings in, 56.
- native and exotic, site requirements and growth rate, Mo. 47.
- nurseries, fusiform rust control in, 649.
- of eastern North America, their woodcraft and wildlife uses, 200.
- orchard, viruslike leaf mottling and chlorosis, Oreg. 641.
- propagating methods, Okla. 763.
- propagation by seed, Okla. 194.
- ring(s)—

- analysis, methods of correlation, 317.
- as climatic records, 13.
- formation and interpretation, 170.
- measuring, methods and instruments for, 316.
- studies of pines in Arkansas, 201.
- seed, forest, of North America, 200.
- shade, insects in Maryland, 784.
- shelterbelt, see Shelterbelt.
- spacing, effect on diameter development, Vt. 483.
- troubles during a wet summer, N.J. 213.
- vascular diseases, chemotherapy for, 650.
- Victorian forest, wood decay in, fungi associated with, 497.

*Trematodes* of subfamily Notocotylinae, life history studies, 230.

## Tricacetin v. glucose as nutrient in feeds, 797.

*Tribolium*—

- castaneum*, see Flour beetle, red.
- confusum*, see Flour beetle, confused.

## Trichinosis, U.S.D.A. 98.

*Trichodectes ovis* control, Ga. 682.*Trichoderma lignorum* on loblolly pine sapwood, effect, 216.*Trichomonas foetus*—

- bacteria-free strain, isolation and growth, 242.
- differentiating from other protozoa in diagnosis of trichomoniasis in cattle, 682.

## infection in bulls by experimental exposure, 820.

## inoculations with in rats and mice, 364.

## Trichomoniasis—

- bovine genital, U.S.D.A. 98.
- bovine, geographical distribution, 527.
- clinical observations in, 244.
- in cattle, diagnosis, differentiating *Trichomonas foetus* from other protozoa in, 682.
- of lower digestive tract of turkeys, 532.
- of upper digestive tract of domesticated birds, 532.
- studies, Kans. 676.

*Trichostrongylus*—

- calcaratus*, parasite of squirrel, 497.
- colubriformis* in range sheep, phenothiazine-medicated pellets for, 103.
- spp., percentage incidence in cattle, 101.

*Trichuris*—

- dispar*, anthelmintic efficiency of Flcin against, 247.
- spp., percentage incidence in cattle, 101.

*Trillium*, cytological studies, N.Y.State 193.*Tripsacum*, *Euchlaena*, and corn, genetic and cytological relations, Tex. 42.*Triasolous murgantiae*, introduction and recovery in California, 499.*Tritonaa fleaa*, bionomics and morphology, 227.*Trogoderma fajas* in insect nests, 74.*Trombicula* sp., parasite of squirrel, 498.

## Trombiculinae, larval, descriptions of 12 new species, 372.

## Truck crop(s)—

- boron requirements, N.C. 446.
- growing, relative risks involved, determination, 394.
- in Copiah Co., receipts, expenses, prices, etc., Miss. 536.
- insects studies, Tex. 73.

## Truck farmers, better income for, with improved markets, Miss. 269.

## Truckee River runoff, a 100-yr. record, 304.

## Trucks, refrigerator, methyl bromide fumigation of, 783.

## Trypsin—

- activity from  $-70^{\circ}$  to  $50^{\circ}$  C., kinetics as function of temperature of, 289.
- crystalline, inactivation of, photochemical yield for, 585.

## Tryptophan in protein hydrolyzates, new color test for, 730.

## Tuberculin and other diagnostic tests, U.S.D.A. 676.

## Tuberculosis—

- and its eradication, U.S.D.A. 97.
- avian, Michigan plan to combat, 814.
- bovine, eradication in the United States and effects on human health, 814.
- diagnosis, value of blood examinations in, 814.
- eradication, 820.
- eradication, no-visible-lesion case problem in, 814.
- eradication work, efficiency and value of, 814.
- pulmonary, vitamin A and ascorbic acid in, 282.
- report of committee on, 814.
- studies, U.S.D.A., 676.

## Tularemia in sheep, role of Rocky Mountain spotted fever tick in, 102.

## Tung—

- buds, effect of chemical treatments in prolonging dormancy, 29.
- iron deficiency in Florida, 484.
- leaves, chlorosis and necrosis of, cause, 649.
- oil meal, solvent-extracted, feeding value for chicks, 236.

## Tung—Continued.

- oil, replacement by castor oil, U.S.D.A. 627.
- pollen, storage experiments, 199.
- seed, germination, effect of stratification and planting time, 199.
- seed selection, importance, 767.
- tree(s)—
  - adaptation studies, Ga.Coastal Plain, 331.
  - development of pistillate flower and structure of fruit, 465.
  - fertilizer experiments and cultural methods, La. 341.
  - fertilizer, variety, and propagation studies, Miss. 331.
  - foliage poisoning of cattle, 100, Fla. 526.
  - phosphorus compared with other fertilizers for, 627.

## Turf—

- diseases, control, R.I. 344.
- diseases, control, mercury substitutes for, N.J. 62.
- fungicide, new, named Thiosan, 206.

## Turkey(s)—

- breeders, management, N.J. 806.
- breeding and cross-breeding studies, N.C. 468.
- breeds, comparison, 378.
- Bronze, gains in weight made by male and female, 806.
- cross-breeding and heterosis in, 37.
- disease, choleralike, Mich. 248.
- eggs, hatchability, and riboflavin, Pa. 667.
- eggs, length of incubation period, effect of age and weight, 519.
- eradication of paratyphoid disease in by sanitation, N.C. 532.
- feathers, fertilizing value, Oreg. 595.
- feeding and confinement rearing experiment, Mich. 670.
- growing under semiconfined conditions, Tex. 85.
- growth of tarsometatarsus, relative, 613.
- leg bone deformities, 519.
- marketing, Tex. 110.
- of different breeds, composition, 377.
- pH of digestive tracts of, 236.
- physical and chemical composition, 700.
- poults—
  - calcium and phosphorus requirements, Tex. 85.
  - finishing, rations for, Tex. 85.
  - hatching, separate incubators for, Pa. 667.
  - infectious omphalitis of and impetigo staphylogenes in man, 105.
  - nutrition, significance of blotin in, 376.
  - protein needs, Tex. 85.
  - protein utilization from various sources by, Nebr. 84.
  - vitamin D requirement, U.S.D.A. 665.
- production, lights in, Pa. 667.

**Turkey(s)**—Continued.

- production, rations and breeding for, Kans. 686.
- protein supplements for, comparison, Mo. 84.
- range v. cut green feeds for, Pa. 687.
- rations, alfalfa meal in, Utah 670.
- respiratory diseases, U.S.D.A. 98.
- respiratory-nervous disorder in, 826.
- riboflavin requirement for hatchability and growth, 376.
- short spined, skeletal abnormalities, 183.
- storage of vitamin A by, 89.
- strain differences in, Tex. 35.
- wild, food habit trends in Missouri, 381.
- young, detecting salmonellosis in, 105.

*Turnera* to *Ungnadia*, host-parasite check-list revision, U.S.D.A. 343.

**Turnip(s)**—

- aphid studies, Tex. 73.
- greens, ascorbic acid in, factors affecting, Ga. 699.
- growth, effect of natural fertilizer materials, 185.

**Turpentine**—

- products from, U.S.D.A. 723.
- separating into components, U.S.D.A. 723.

Tuskegee Institute notes, 427.

Twig girdler, pest of hickory, 219.

**Tyrocidine**—

- d*-amino acids in, 583.
- effect on bacteria, 457.
- in vitro and in vivo studies, 815.

Tyrosine, metabolism, role of ascorbic acid in, 419.

Tyrosine, in vitro and in vivo studies, 815.

**Udder**—

- of cow, development, structure, and physiological functioning, Minn. 380.
- streptococci of dairy cows, effect of sulfanilamide on, Mo. 99.

Ultracentrifugation results, computation, alignment chart for, 346.

**Ultraviolet**—

- irradiation, elimination of contaminants with, 208.
- radiation, bactericidal action on airborne organisms, 26.

Undulant fever studies, 814.

**United States Department of Agriculture**—

- Bureau of Agricultural Economics, *see* Bureau of Agricultural Economics.
- Bureau of Dairy Industry, *see* Bureau of Dairy Industry.
- Bureau of Entomology and Plant Quarantine, *see* Bureau of Entomology and Plant Quarantine.
- list of available publications, 142.
- slides, catalog and price, U.S.D.A. 699.

**Urea**—

- as protein substitute in ration of ruminants, 281.
- as soil disinfectant, U.S.D.A. 640.

**Urea**—Continued.

hydrolysis in soils, enzymatic v. microbial concepts, 598.

in chick rations, Okla. 797.

utilization by ruminants, effect of starch in ration, 667.

utilization by young calves, 90.

Uredinales, taxonomic study, 642.

Uric acid excretion of young children, effect of diet, 410.

**Urinary**—

calculi in sheep, 389.

17-ketosteroids, neutral, colorimetric assay, elimination of errors in, 589.

tract in small animals, effect of sulfonamides on, 818.

**Urine**—

ascorbic acid determination in, 153.

extraction of lactogen from, Mo. 34.

of pyridoxin-deficient rats, green pigment-producing compound in, 727.

riboflavin in, fluorimetric estimation, 591.

*Urocystis tritici*, physiologic races in, 772.

*Uromyces striatus*, notes, 487.

Utah College notes, 429, 575.

Utah Station notes, 429, 575.

**Vaccinium**—

host-parasite check-list revision, U.S.D.A. 640.

species, cytology, 467.

**Vanilla**—

beans, processing and chemical changes involved in flavor development, P.R. 579.

culture, pollination, and breeding, P.R. 628.

curing, 442.

plantings, injury by snail and slug, P.R. 636.

Variation, coefficients of, limitations to use of, 693.

Veal, dressed, market classes and grades, U.S.D.A. 269.

**Vegetable(s)**—

and fruit dehydrator, Nebr. 105.

areas in Florida, production credit, Fla. 119.

ascorbic acid in, factors in processing affecting, 713.

canning crops, quality studies, N.Y.State 272.

canning methods, Calif. 409.

culture tests, R.I. 331.

culture, value of lime in, Ark. 762.

curly top resistance in, Oreg. 641.

damping-off, control, effect of nitrogen, Mass. 65.

**dehydrated**—

nutritive value and palatability, N.Y.State 272.

packaging, N.Y.State 157.

rapidly refreshing, 11.

**dehydration**—

adequacy of blanching process in, 440.

## Vegetable(s)—Continued.

## dehydration—continued.

by farmers' cooperative associations,  
U.S.D.A. 404.

past and present, 440.

studies, 157, 158, 440, N.Y.Stat 287.  
tests, 295.

desirable, for fall planting, Miss. 191.

## diseases—

bordeaux and fixed copper sprays or  
dusts for, Ohio 344.

effect of weather, N.J. 490.

in Massachusetts, U. S. D. A. 58.

in Nebraska, 490.

in New Jersey, effect of weather,  
U.S.D.A. 640.

on Chicago market in 1940-41,  
U.S.D.A. 343.

studies, Kans. 640.

dried, made into bricks freed from air  
in new packaging process, N.Y.State  
850.

early, fertilizers for, Ohio 331.

effect of boron on, Oreg. 628.

fertilizer placement, Ark. 762.

fertilizer tests, Miss. 331.

fertilizers for, Okla. 763.

freezing preservation, 848, N.Y.State 272,  
U.S.D.A. 723.

freezing procedures, 272.

fresh and canned, quality, relation to  
retail prices, Ohio 394.

fresh, selling cooperatively, U.S.D.A. 404.

frozen, determining maturity of, 150.

gardens, early, time for plowing and  
preparing soil for, Miss. 629.

growth and production, effect of lime on,  
Ark. 46.

home canning U.S.D.A. 129.

home drying, U.S.D.A. 130.

insect studies, N.Y.State 218.

irrigation, Ark 762, Okla. 763.

irrigation and mulching, Nebr. 47.

## juices—

expressed, vitamin C, carotene, cal-  
cium, and phosphorus in, 559.

home preparation and preservation  
N.Y.State 129.

loss of flavor and of food value in  
preparation, 155.

making in small lots, N.Y.State 274.

preparation and preservation, N.Y.  
State 149.

special problems in preparation,  
N.Y.State 274.

leafy, nutritive value, Miss. 544.

marketing, Kans. 693.

mineral composition in representative re-  
gions, relation to nutritive value, Tex.  
127.

nutrient constituents per acre and per  
acre man-hour, 546, 855.

nutrition of, Mo. 46.

of New York State, vitamin C in, N.Y.  
State 284.

oils, *see* Oil(s), vegetable.

## Vegetable(s)—Continued.

phosphorus and calcium in, distribution,  
133.

possibility of overirrigating, Pa. 628.

preparing for frozen food lockers, 700.

quality and nutritive value, effect of  
various cooking methods, 847.

refuse, insect pests breeding in, 72.

relation of glutamine and asparagine in,  
R.I. 331.

relation of percentage of margin to sales  
and attractiveness of display to sales,  
Ohio 394.

riboflavin determination in, 437.

seed production in Utah, possibilities,  
Utah 191.

seed treatment recommendations, R.I.  
344.

seed treatment studies, 484.

selection for dehydration value, N.Y.  
State 191.

southern grown, composition, Ga. 699.

storage, Ga. 627.

storage as help in wartime, Colo. 763.

studies with, Tex. 47.

thiamin determination in, 438.

use of commercial fertilizers for, Mont.  
628.

use of overhead irrigation on, Ga. 627.

value of stable manure for, Ark. 763.

varieties for irrigated central Washing-  
ton, 191.

varieties, new, tests, Okla. 763.

variety tests, Ga.Coastal Plain 331, Kans.  
628, Miss. 331, Nebr. 47, Oreg. 628,

Pa. 628, R.I. 331.

vitamin content, N.Y.State 272.

wartime marketing problems of, Ark.  
841.

wastes, utilization, U.S.D.A. 723.

weevil studies, Tex. 73.

Vegetation—*see also* Flora(s) and Plant(s).

and forest wealth of Ecuador, 169.

and natural resources of British Hon-  
duras, 169.

of Jamaica, 169.

of Trumbull County, Ohio 601.

use of water by, 298.

yield and quality, relation to sunlight,  
Tex. 42.

Velvet grass, creeping, control, Oreg. 619.

## Velvetbean(s)—

caterpillar, biology and control, La. 362.

variety tests, Ga.Coastal Plain 325.

Verbena, new pest of, 362.

Vermont Station notes, 143, 430.

Vermont Station report, 574.

Vermont University notes, 143.

*Veronica kraussii*, injury to vanilla plant-  
ings, P.R. 656.

## Verticillium—

diseases, new records for, U.S.D.A. 58.

*matthusei* in mushroom soil, control  
with chloropicrin, 355.

wilt of chrysanthemum, control, Ohio  
344.

## Vetch—

- bruchid in Georgia, 499.
- culture, drainage highly important factor, Miss. 186.
- diseases, Ga. 640.
- fertilizer tests, Ga. 617, Miss. 159.
- for green manure, Utah 186.
- growth, comparison of phosphates for, Miss. 186.
- hairry, as green manure crop for cotton, 185.
- hairry, fertilizer tests, Miss. 325.
- hairry, most profitable fertilizers for, Miss. 325.
- hairry, yield increased from lime and phosphate, Miss. 618.
- moderate use of phosphate and lime for, Miss. 186.
- planting for seed production, 185.
- superior varieties or strains grown by station, Oreg. 619.
- variety tests, Tex. 42.

Veterinary—*see also* Animal diseases.

surgery notes, 383.

Viburnum to *Vitis*, host-parasite check-list revision, U.S.D.A. 640.

## Viola—

- fabia*, histological responses to indoleacetic acid, 742.
- sativa*, karyological races, 180.

## Vine weevil, black, control, 72.

## Violet(s)—

- genetic studies, Vt. 467.
- scab, additional records, 779.

## Virus(es)—

- bacterial, inactivated and active, interference between, 769.
- bacterial, interference between, and mechanism of virus growth, 769.
- diseases and respiration, 769.
- diseases of plants and animals, treatise, 485.
- diseases of yellows type, spread under field conditions, 61.
- in primordial meristem, 205.
- nature of, recent evidence regarding, 846.
- nomenclature and classification, 205.
- Nomenclature and Committees, comment on paper, 346.
- research, review, 485.

## Visual mechanisms, symposium, 130.

## Vitamin A—

## absorption—

- and retention by hens on normal and low fat rations, 803.
- experiments, 135.
- metabolism, and storage, 413.
- and carotene, utilization in rat, 551.
- and dark adaptation, effect of alcohol, benzedrine, and vitamin C, 552.
- and visual systems, 130.
- chemistry and physiological activity, 413.
- deficiency (ies)—
  - and nervous system, 136.
  - criteria, 282.

## Vitamin A—Continued.

## deficiency (ies)—continued.

- damage to reproductive organs from, Ohio 380.
- diagnosing, simple methods, 413.
- effect on reproduction in farm animals, Ohio 318.
- in cattle and cystic pituitary, 375.
- in cattle, effect on reproductive functions and dilution and quality of semen, U.S.D.A. 670.
- in rat, early signs, relation to liver stores, 708.
- dietary levels, relation to dark adaptation of children, 709.
- distribution, changes in choline deficiency, 413.
- effect on immunological reactions in man, 551.
- excess stores, fate during depletion, 708.
- in blood, relation to body reserves, 135.
- in blood, relation to dark adaptation, 552.
- in liver of rat, state of, 707.
- in milk, effect of shark-liver oil in feed, 673.
- in milk, relation to pasture and feeding practices, seasonal variation, 807.
- in pickles from different areas, 295.
- in pig feeding, 234.
- in prepared foods, 281.
- in shad and mackerel oils, 706.
- in various solvents, ultraviolet absorption, 8.
- in willow oak acorns, effect in chick diet, 803.
- intake, education as means of improving, Pa. 701.
- metabolism of human subjects, R.I. 409.
- mobilization by alcohols from its stores in tissues, 855.
- of liver biopsy specimens and plasma vitamin A in man, comparison, 706.
- potency of liver, relation to chemical analyses, 731.
- potency of milk and shark-liver oil, 807.
- prairie hay as source of, Okla. 808.
- requirements—
  - for conception in dairy cattle, Tex. 92.
  - for fattening beef cattle, Tex. 85.
  - of beef cattle and sheep, Tex. 85.
  - of cattle, sheep, and swine, 798.
  - of dairy cattle, 807.
  - of pigs, Tex. 85.
  - of rat, intake relation to growth and concentration in retina, 707.
- rich milk, producing, Ind. 809.
- storage by growing turkeys, 89.
- storage in liver of rats, Pa. 701.
- studies with rats and pigs, 234.
- ultraviolet absorption maximum of, effect of solvent, 590.
- utilization, effect of fat level in diet, 553.
- value of fresh and dehydrated carrots, 281.

- Vitamin B<sub>1</sub>**—*see also* Thiamin.  
 and endurance, 709.  
 bibliography supplement, 414.  
 clinical aspects, 705.  
 deficiency diets in rats, studies of gastrointestinal tract, 139.  
 determination, by yeast fermentation method, 293.  
 determination, spectrophotometric accuracy, 293.  
 effect on concentration of glucose optimal for fungi fruiting, 602.  
 effect on crops of North Carolina soils, 610.  
 in Indian foods, 709.  
 in yeast and bread and stability during bread making, 292.  
 loss on baking, 151.  
 royal jelly and bee bread as source, 82.  
 stability in manufacture of bread, 837.  
 studies, Tex. 599.  
 synthesis by yeast, 555.
- Vitamin B<sub>2</sub>**—  
 loss from yeast during dissimilation, 742.  
 royal jelly and bee bread as source, 82.
- Vitamin B<sub>6</sub>**—*see also* Pyridoxin.  
 effect on egg production and hatchability, 804.  
 in nutrition of pig, 516.  
 royal jelly and bee bread as source, 82.
- Vitamin B complex**—  
 and fat metabolism, 136.  
 deficiency, effect on gastric emptying and intestinal motility, 136.  
 deficiency in young pigs, sensory neuron degeneration in, control, 799.  
 experimental deficiency, mental changes in, 554.  
 for swine, deficiencies, U.S.D.A. 665.  
 in beers, ales, and malt tonics, 856.  
 in nutrition of dogs, 87.  
 meat as source, 281.  
 requirements for lactation, Ark. 284.
- Vitamin C**—*see also* Ascorbic acid.  
 administration in a large institution, effect on general health and resistance to infection, 419.  
 and wound healing, 563.  
 determination, color reaction for dehydroascorbic acid useful in, 9.  
 effect on immunological reactions in man, 551.  
 for sterility in farm animals, 35.

 in New York State vegetables, N.Y.State 284.  
 in normal nutrition, 714.  
 in persimmon leaves and fruits, 313.  
 in pickles from different areas, 295.  
 in rose hips, 714.  
 in snap beans, 627.
- Vitamin C**—Continued.  
 in strawberries, determination, variations in samples, 713.  
 in strawberries, sun-ripened v. shade-ripened, N.C. 476.  
 loss from turnip greens, effect of storing and cooking, Miss. 409.  
 loss in making evaporated milk, Pa. 671.  
 loss in milk prevented by cold temperature, Ohio 380.  
 nutritional status of human subjects, R.I. 409.  
 royal jelly and bee bread as source, 82.
- Vitamin D**—  
 assay, A. O. A. C., 377.  
 assay, importance of using "litter-mate" comparisons, 284.  
 assay technic with radioactive strontium, 438.  
 deficiency of dairy cattle, 566.  
 determination, A. O. A. C. chick method, use of toes rather than tibiae in, 735.  
 from different sources, effect on bone ash curve, 377.  
 from soft curd and homogenized milk, effectiveness on rickets, Ohio 380.  
 in milk, Ohio 380.  
 in milk, control and verification of, 91.  
 in milk, effect of irradiation of cows, Ohio 380.  
 in shad and mackerel oils, 706.  
 in shark-liver oil, 798.  
 massive doses, prevention of dental caries by, 569.  
 parathyroid glands, and calcium metabolism, 91.  
 requirement of turkey poults, U.S.D.A. 665.  
 requirements of White Leghorn chicks v. crossbreds, 518.  
 single massive doses, feeding to birds, 377.  
 stability, 89, 377.
- Vitamin E**—*see also* Tocopherol.  
 assay tests, 564.  
 distribution in rat tissues, 561.  
 in grain milling products and effect of bleaching on, 715.  
 role in prevention of sterility, 472.
- Vitamin G**, *see* Riboflavin.
- Vitamin H**, biotin, and coenzyme R, review of literature, 863.
- Vitamin K**—  
 determination, colorimetric method, 593.  
 papers on, 705.
- Vitamin P** deficiency, experimental, 420.
- Vitamin(s)**—  
 advances in knowledge of, 854.  
 and micro-organisms, 413.  
 antihemorrhagic, *see* Vitamin K.  
 antineuritic, *see* Vitamin B<sub>1</sub>.  
 antirachitic, *see* Vitamin D.  
 as growth substances for plants, 25.  
 biological action, symposium, 705.  
 chemistry and physiology, 281.  
 deficiency, clinical, chemical measurement and control, 706.

## Vitamin(s)—Continued.

- deficiency diseases, 565.
- for livestock, Mo. 514.
- in food, relation to human nutrition, Kans. 701.
- in fungi, 705.
- in grasses of Nebraska, Nebr. 84.
- in mixtures, proper use of, 705.
- nature and function, 295.
- requirement of rat, effect of exercise, Pa. 701.
- social implications, 184.
- studies, Mo. 134.
- synthesis by a yeast converted from heterotrophic to autotrophic habit, 28.
- varying amounts in the diet, effect on animal body, Kans. 701.
- Walls, rammed earth, soil admixtures for, 253
- War and farm work, U.S.D.A. 111.
- War program, role of insecticides and disinfectants in, 657.
- Washing compounds, alkaline, germicidal properties evaluation, 243.
- Washington College notes, 575.
- Washington Station notes, 575, 722
- Wasp, New Calendonian cockroach, biological notes, 74.
- Wasps nests as reservoirs and sources of stored products pests, 73.
- Wasps, wood, siricid, and symbiosis, 654.
- Waste materials, nitrogen content, N.J. 738.
- Water—
  - absorption at low soil temperatures, species differences, 743.
  - and soil conservation studies, Tex. 15.
  - and soil losses under different conditions, N.Y.State 160.
  - and soil losses under different cropping methods, Ark. 15.
  - attack on dry cohesive soil systems, mechanism of, 450.
  - bearing materials, permeability determination methods, 106.
  - conservation, effect of lining irrigation canals, Utah 595.
  - entry into roots, device for measuring, 463.
  - evaporation and consumptive use, empirical formulas for estimating, 449.
  - ground, areas in Southwest, classes of, present and future use, 448.
  - ground, control and conservation, relation to food production, U.S.D.A. 827.
  - heater, solar, P.R. 692.
  - heaters, plug-in, Pa. 688.
  - irrigation, *see* Irrigation water.
  - levels and artesian pressure in observation wells, 106.
  - management, relation to grassland farming, 107.
  - movement through soils, relation to pores, 17.
  - pipes, protection against freezing by heating cable, Pa. 688.
  - resources of Willamette Valley, Oregon, 828.

## Water—Continued.

- stage recorder charts, determining volume of runoff from, 252.
- supply(ies)—
  - in Georgia, public, industrial quality, 688.
  - of Dakota sandstone in Ellendale-Jamestown area, 828.
  - of Hawaii, 392.
  - of United States, 106, 392.
  - of United States, Ohio River Basin, 828.
  - public, removal of fluorides from, 532.
- Waterfowl in British Columbia, studies, 360.
- Water-hyacinth leaf spot disease, cause, 781.
- Watermelon(s)—
  - cultural tests, Ga.Coastal Plain 831.
  - fertilizer tests, Ga.Coastal Plain 831.
  - Fusarium* wilt resistance, tests for, Tex. 60.
  - growing district, serious damage by *Fusarium* wilt in, 203.
  - wilt resistance and acetic acid, 491.
  - wilt resistance, breeding for, Ga. 627.
  - wilt-resistant strains, Miss. 203.
- Watershed(s)—
  - at West Tarkio Creek and Tarkio River, hydrologic studies, U.S.D.A. 158.
  - North Appalachian Experimental, at Coshocton, Ohio, U.S.D.A. 594.
- Waterways, vegetated, tests on, Okla. 164
- Waxy coatings on cucurbit fruit, study of permeability to respiratory gases, 607.
- Weasel, short-tailed, winter food habits, 360.
- Weather—*see also* Meteorological observations and Meteorology.
  - astronomy, and maps, treatise, 298.
  - effect on vegetable diseases, N.J. 490.
  - forecasting, basic principles, 735
  - of Scotland in 1941, 440.
  - studies, R.I. 290.
- Webworms, control, R.I. 362.
- Weed(s)—
  - control, Miss. 186.
  - control on closely cut turf and on fairways, R.I. 326.
  - non-noxious, for green manure, Utah 186.
  - pasture, control, Tex. 42.
  - seeds, killing with chloropicrin, Ohio 826.
- Weevils, protection of corn from, Miss. 499.
- Weights and measures in United States, inspection and control, U.S.D.A. 401.
- Well water as milk-cooling medium, Pa. 671.
- Wells, observation, water levels and artesian pressure in, 106.
- West Virginia Station notes, 722.
- West Virginia University notes, 722.
- Wethers, ground Love grass hay for, Okla. 797.
- Wetting agents, properties and applications, 520.
- Whale and fish meal, nutritive value, 231.
- Whale meat meal in chick ration, 878.

## Wheat—

- agreement, international, U.S.D.A. 124, 405.
- agreement, "New World," U.S.D.A. 123.
- and wheat products, nicotinic acid, pantothenic acid, and pyridoxin in, 557.
- as livestock feed, Utah 687.
- auxin extraction from, 462.
- average acre yields and production costs, Alaska 617.
- basin, ordinary, and contour listing for, Kans. 618.
- bin fumigation tests, Okla. 756.
- bins, fumigating, safer methods, Okla. 783.
- breeding, Alaska 617, Ga. 617, Kans. 618, Mo. 41, Mont. 618, Nebr. 41, Okla. 755, Oreg. 619, Tex. 42, U.S.D.A. 616.
- brown necrosis and *Alternaria* blotch, 348.
- bunt, *see* Wheat smut, stinking.
- Canadian hard red, thiamin in, variability, 415.
- carbohydrate metabolism under deficient moisture, 31.
- cold resistance, factors affecting, Nebr. 41.
- Comanche and Pawnee, new hard red winter, high-yielding and leaf rust resistant, U.S.D.A. 616.
- combining, proper stages for, Pa. 619.
- composition, factors affecting, 21.
- conditioning requirements, and their effect on milling and baking, Kans. 579.
- culture, continuous v. rotation, N.Dak. 330.
- culture tests, Ga. Coastal Plain 325, Kans. 618, Mont. 619, Tex. 42.
- disease resistance in, breeding for, Kans. 640.
- dusted, viability after storage, 206.
- estimating reduction in yield from hesian fly infestation, U.S.D.A. 794.
- eyespot in Great Britain, cause, 772.
- Fairfield, description, Ind. 762.
- fertilizer tests, Ga. 617, Kans. 618.
- field survey, Ohio 370.
- flour, *see* Flour.
- germination and baking quality, effect of carbon disulfide, Okla. 190.
- grading and protein tests of grain inspection laboratory, Mont. 619.
- growth and yield, relation to environment, Kans. 618.
- hard red winter, quality characteristics, U.S.D.A. 625.
- hybrids, inheritance and interrelation of components of quality, cold resistance, and morphological characters in, 608.
- in national diets, 128.
- inoculation tests with *Helminthosporium sativum*, antagonism in, 349.
- Kansas, quality, effect of  $ICl_3$ , ethylene gas, and Cl on, Kans. 579.
- leaf rust damage, forecasting, Okla. 769.

## Wheat—Continued.

- leaf rust, physiologic races, revision, U.S.D.A. 207.
- loose smut control, Okla. 769.
- milling products, vitamin E in, and effect of bleaching, 715.
- mite, brown, covering stubble for control, Okla. 783.
- mosaic virus, heat inactivation in soils, 207.
- North Dakota, quality in 1942, N.Dak. 626.
- nutrients in, effect of soil fertility, Ind. 737.
- Oklahoma, quality improvement, Okla. 755.
- physical properties, factors affecting, Kans. 579.
- phytic acid distribution in, 289.
- Pilot and Rival, resistant to leaf rust, expansion of areas, U.S.D.A. 616.
- plant characters, relation to yield, effect of tillage and sequence treatments, 762.
- planting tests, Nebr. 41.
- policy, wartime, in Canada, 693.
- polyploidy studies, Mo. 41.
- quality, chemical factors affecting, Kans. 579.
- quality during storage, factors affecting, Kans. 688.
- quality, effect of unfavorable weather at harvest, N.Dak. 298.
- quality, inheritance studies of factors affecting, Kans. 618.
- respiration, fermentation, and growth, effect of oxygen tension, 745.
- response to fallow and other tillage practices, Nebr. 41.
- root strength, guide to winter hardiness, Ohio 326.
- rust-resistant, development, N.C. 473.
- rust-resistant variety, new, Utah, 620.
- scab absent in western North Dakota, U.S.D.A. 58.
- scab control, U.S.D.A. 349.
- scab in Virginia, U.S.D.A. 58.
- smut, stinking, control, Mont. 641.
- smut, stinking, in Rumania, distribution, 772.
- smut, stinking, inoculation method for, Nebr. 59.
- species, role of interspecific hybridization in origin and production of new forms, 466.
- spring, drought resistance in, 169.
- spring, heat, light, and drought tolerance in, Kans. 618.
- stabilization in Australia, U.S.D.A. 124.
- stem rust, physiologic races in Portugal, 207.
- stem rust resistant varieties, new, and genetical background, 642.
- superior varieties or strains grown by station, Oreg. 619.

## Wheat—Continued

surplus, conversion into much needed milk, Utah 673.

take-all disease, control, U.S.D.A. 347.

tillage experiments and rotations, Oreg. 619.

use in livestock feeding, Wyo. 373.

varieties, Miss. 41.

varieties grown in West, quality studies, U.S.D.A. 626.

variety tests, Ark. 755, Ga. 617,

Ga. Coastal Plain 325, Kans. 618, Miss.

325, Mont. 618, Nebr. 41, Okla. 755,

Tex. 42.

wind erosion, relation to different types of tillage preparation, Tex. 42.

winter, as supplement to native grass for pasture, Kans. 618.

winter, leaf and stem rust races, combined resistance to, Kans. 640.

winter, physiological study, Kans. 603.

world survey and outlook, 270.

yield and milling and baking quality, effect of fertilizers, Okla. 756.

yield and mineral content, effect of minor element compounds, 456.

yields, crop rotation v. superphosphate for, Ark. 755.

## Wheatgrass—

crested—

culture tests, Mont. 619.

Fairway, sowing with alfalfa to keep out "cheat" grass, Oreg. 619.

feeding tests for steers, Mont. 666.

for wintering steers, Mont. 667.

grazing studies, Mont. 619.

superiority in pasture experiments, U.S.D.A. 617.

uses, Mont. 619.

new tetraploid, from Nevada, 317.

Whey solubles as source of growth factors in chick rations, 376.

White ants, *see* Termite(s).

## White grubs—

biology, control, and taxonomy, Tex. 73.

control, Conn. [New Haven] 499.

control with dichloroethyl ether, 78.

in forest nurseries of Southeast, tests of chemicals for control, 227.

on wheat, Kans. 655.

## White pine—

blister rust—

control, Ohio 344.

control in Northwest, developments, 216.

control in Washington State, 496.

control policies in New York State, 496.

spread in 1941, 651.

forests, western, economic management, U.S.D.A. 55.

piles, creosote treatment, 254.

sapwood and compression wood, polyuronide hemicelluloses isolated from, 584.

## White pine—Continued.

seedlings in soils of low fertility, my-

corhizal inoculation of, 56.

species, analysis of wood, 465.

wolf trees, profits from cutting, 201.

Whitebrush poisoning in horses, 103.

Whitedish meal, nutritive value, 231.

Whitefly, redbud, studies, Kans. 655.

White-fringed beetle(s)—

fumigation of small land areas for control, 791.

new species, 367.

Wild rice, vitamins in, 857.

## Wildlife—

as valuable resource, Pa. 652.

cover, northeastern forest, plant pathology in relation to, 359.

diseases and parasites, U.S.D.A. 99.

Forest Station, Huntington, history, policy, and program, 217.

production handbook, U.S.D.A. 497.

Willow blight in West Virginia, 497.

Windbreaks, *see* Shelterbelt.

Winds, velocity and direction, 299.

## Wine—

control program in Argentina, U.S.D.A. 696.

sulfur dioxide in, effect of storage, 442.

Wire and fencing, atmospheric exposure, Tex. 106.

## Wireworm(s)—

control, 654, Pa. 652.

control, progress in, N.Dak. 659.

eastern field, control on shade-grown tobacco, 782.

on wheat, Kans. 655.

organic fumigants for, tests, 504.

Pacific coast, value of trapping males and parthenogenicity of females, 78.

populations, effect of sunflowers, Ohio 362.

rate of development, effect of sterile and unsterile foods, 361.

sand, La. 362.

seasonal vertical distribution in soil relation to control, 77.

studies, 367, Ohio 362.

sugar beet, dichloroethyl ether for control, 790.

Witches'-broom disease, susceptibility of selections of cacao to, 494.

*Wohlfahrtia meigeni*, notes, Mont. 655.

## Women, college—

Ca, P, and N metabolism, 852.

calorie intakes, 275.

nutritional status, Kans. 701.

Wood—*see also* Lumber and Timber.

decay susceptibility, effect of urea and other nitrogen compounds, 651.

decayed, calorific value and chemical composition, 652.

fuel in wartime, U.S.D.A. 57.

preservation, availability of materials for in 1942, 254.

preservatives, products of Disco-type low-temperature coal tar as, 254.

## Wood— Continued.

- preserved, use in home construction, 254.
- treated, and preservatives used in U. S. in 1941, quantity, 255.
- treated, chromates and arsenates in, determination, 154.

## Wood-borers, notes, 654.

## Woodcock populations, breeding, 398.

## Woodland(s)—

- place in farm organization, N.H. 263.
- southern, preventing destructive fires in, U.S.D.A. 768.

## Woody plants—

- identification, tabular keys, 309.
- in Idaho, recently active leaf diseases, U.S.D.A. 202.
- leafy cuttings of, treatment with synthetic growth substances, Ohio 46.

## Woody stems, movement of auxin in, 742.

## Wool—

- blended fabrics, how to sell and care for, 865.
- elasticity, relation to chemical structure, 571.
- fibers, density, determination, cross-section-area method, U.S.D.A. 140.
- in mixed fabrics, quantitative determination methods, 421.
- of different breeds, shrinkage, U.S.D.A. 665.
- of Texas, size of sample and determination of grades and shrinkage, Tex. 85.
- powdered, nutritional studies, 545.
- production, Merino, studies, 668.
- quality and fiber diameter, relation, 421.
- quantitative estimation, comparison of methods, 140.
- resistance to digestion by enzymes, cause, 421.
- shrinkage, Mont. 666.
- yield, relation to staple length, U.S.D.A. 665.

Woolly aphid, *see* Apple aphid, woolly.

## Worms, parasitic, seasonal incidence, role of soil temperatures and soil moisture, 531.

## Wound healing—

- and vitamin C, 563.
- review, 677.

## Wren, rock, insect food, 217.

## Wyoming Station notes, 576, 869.

## Wyoming University notes, 576.

*Xanthopastis timais*, biology, 654.*Xenopsylla cheopis*, *see* Rat flea, oriental.

## Xerothermic theory, 443.

## X-ray seed treatments, auxin and calines in seedlings from, 743.

## Yeast(s)—

- budding and conjugation in, mechanics, 601.
- debuttized brewers', for enrichment of white bread, 555.
- growth-promoting effect of diaminocarboxylic acid from biotin, 711.
- new acidifying, 740.
- osmophilic, nutritive requirements, 460.
- respiration, stimulation by ultraviolet radiations, 33.
- sporulation stock medium for, 310.
- sugar-tolerant, cause of souring of dried dates, 11.
- vitamin B<sub>1</sub> in, and stability during bread making, 292.

## Yellow scale—

- and its parasite, effect of tartar emetic on, 77.
- fumigation with HCN, 789.

## Yerba maté, U.S.D.A. 124.

## Yew crown gall, 359.

## Youngberries, preservation with sulfurous acid, Ga. 700.

## Youth problems, analysis, Colo. 698.

## Zein—

- hydrolysis, optical rotation of sulfuric acid hydrolyzates of, factors affecting, 582.
- hydrolyzates prepared by autoclaving, threonine deficiency in, 581.
- in concentrated ethyl alcohol, critical peptization temperatures, 724.

*Zecurine stratumatica*, mycorrhizal associate of, 27.

## Zinc—

- in animal and plant nutrition, 456.
- oxide, new larvicide for hornfly control on cattle, 227.
- relations in Utah soils, 599.
- substitutes in fungicidal sprays, 206.

*Zonosemata electa*, studies, Ga. 655.*Zygosaccharomyces*—

- acidifaciens* n.sp. in domestic red wine turning sour, 740.
- nutrillite requirements, 460.
- on dates, 358.

**NEW DELHI.**

[illegible]
